13 The tools package

The tools package provides a variety of utilities for working with R packages. Some of the functions included in this package are:

- `add_datalist`: Adds a data list to a vignette.
- `assertCondition`: Asserts a condition and sets an error message if the condition is not met.
- `bibstyle`: A function to create and manage bibliography styles.
- `buildVignette`: Builds a vignette from a package.
- `buildVignettes`: Builds all vignettes in a package.
- `charsets`: A function to work with character sets.
- `checkFF`: Checks for files that are not found.
- `checkMD5sums`: Checks MD5 sums of files.
- `checkPoFiles`: Checks Portable Object files.
- `checkRd`: Checks Rd files.
- `checkRdaFiles`: Checks Rda files.
- `checkTnF`: Checks for test files.
- `checkVignettes`: Checks vignettes.
- `check_packages_in_dir`: Checks available packages in a directory.
- `codoc`: A function to codify R code.
- `compactPDF`: Compacts PDF files.
- `CRANtools`: Tools for working with CRAN.
- `delimMatch`: Parses and matches delimiters.
- `dependsOnPkgs`: Finds dependencies on other packages.
- `encoded_text_to_latex`: Encodes text to LaTeX.
- `fileutils`: File utility functions.
- `find_gs_cmd`: Finds the Ghostscript command.
- `getVignetteInfo`: Gets information about vignettes.
- `HTMLheader`: Generates HTML headers.
- `HTMLlinks`: generates HTML links.
- `loadRdMacros`: Loads Rd macros.
- `makevars`: Generates Makefile variables.
- `make_translations_pkg`: Generates translation files.
- `md5sum`: Calculates MD5 sums.
- `package_dependencies`: Lists package dependencies.
- `package_native Routine_registration_skeleton`: Generates skeleton files for native routines.
- `parseLatex`: Parses LaTeX.
- `parse_Rd`: Parses Rd files.
- `pskill`: Sends a signal to a process.
- `psnice`: Adjusts process nice.
- `QC`: Quality control.
- `Rcmd`: Command line interface.
- `Rd2HTML`: Converts Rd files to HTML.
- `Rd2txt_options`: Generates Rd to plain text.
- `Rdiff`: Performs a diff on Rd files.
- `Rdindex`: Generates Rd index.
- `RdTextFilter`: Filters Rd text.
- `Rdutils`: Utility functions for Rd files.
- `read.00Index`: Reads Rd index files.
- `showNonASCII`: Shows non-ASCII characters.

For more information, please refer to the documentation of the tools package.

Part I
Chapter 1

The base package

---

base-package  The R Base Package

Description

Base R functions

Details

This package contains the basic functions which let R function as a language: arithmetic, input/output, basic programming support, etc. Its contents are available through inheritance from any environment.

For a complete list of functions, use `library(help = "base")`.

---

.bincode  Bin a Numeric Vector

Description

Bin a numeric vector and return integer codes for the binning.

Usage

`.bincode(x, breaks, right = TRUE, include.lowest = FALSE)`

Arguments

- `x`  a numeric vector which is to be converted to integer codes by binning.
- `breaks`  a numeric vector of two or more cut points, sorted in increasing order.
- `right`  logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- `include.lowest`  logical, indicating if an ‘x[i]’ equal to the lowest (or highest, for `right = FALSE`) ‘breaks’ value should be included in the first (or last) bin.
Details

This is a 'barebones' version of `cut.default(labels = FALSE)` intended for use in other functions which have checked the arguments passed. (Note the different order of the arguments they have in common.)

Unlike `cut`, the breaks do not need to be unique. An input can only fall into a zero-length interval if it is closed at both ends, so only if `include.lowest = TRUE` and it is the first (or last for `right = FALSE`) interval.

Value

An integer vector of the same length as `x` indicating which bin each element falls into (the leftmost bin being bin 1). NaN and NA elements of `x` are mapped to NA codes, as are values outside range of breaks.

See Also

cut, tabulate

Examples

```r
## An example with non-unique breaks:
x <- c(0, 0.01, 0.5, 0.99, 1)
b <- c(0, 0, 1, 1)
.bincode(x, b, TRUE)
.bincode(x, b, FALSE)
.bincode(x, b, TRUE, TRUE)
.bincode(x, b, FALSE, TRUE)
```

### .Device

Lists of Open/Active Graphics Devices

Description

A pairlist of the names of open graphics devices is stored in `.Devices`. The name of the active device (see `dev.cur`) is stored in `.Device`. Both are symbols and so appear in the base namespace.

Value

`.Device` is a length-one character vector.

`.Devices` is a pairlist of length-one character vectors. The first entry is always "null device", and there are as many entries as the maximal number of graphics devices which have been simultaneously active. If a device has been removed, its entry will be "" until the device number is reused.

Devices may add attributes to the character vector: for example devices which write to a file may record its path in attribute "filepath".

Description

.Machine is a variable holding information on the numerical characteristics of the machine \( R \) is running on, such as the largest double or integer and the machine’s precision.

Usage

.Machine

Details

The algorithm is based on Cody’s (1988) subroutine MACHAR. As all current implementations of \( R \) use 32-bit integers and use IEC 60559 floating-point (double precision) arithmetic, all but three of the last four values are the same for almost all \( R \) builds.

Note that on most platforms smaller positive values than \( .Machine \$double.xmin \) can occur. On a typical \( R \) platform the smallest positive double is about \( 5 \times 10^{-324} \).

Value

A list with components

double.eps  the smallest positive floating-point number \( x \) such that \( 1 + x \neq 1 \). It equals \( double.base ^ ulp.digits \) if either \( double.base \) is 2 or \( double.rounding \) is 0; otherwise, it is \( (double.base ^ double.ulp.digits) / 2 \). Normally \( 2.220446e-16 \).

double.neg.eps  a small positive floating-point number \( x \) such that \( 1 - x \neq 1 \). It equals \( double.base ^ double.neg.ulp.digits \) if \( double.base \) is 2 or \( double.rounding \) is 0; otherwise, it is \( (double.base ^ double.neg.ulp.digits) / 2 \). Normally \( 1.110223e-16 \).

Note that as \( double.neg.ulp.digits \) is bounded below by \( -(double.digits + 3) \), \( double.neg.eps \) may not be the smallest number that can alter 1 by subtraction.

double.xmin  the smallest non-zero normalized floating-point number, a power of the radix, i.e., \( double.base ^ double.min.exp \). Normally \( 2.225074e-308 \).

double.xmax  the largest normalized floating-point number. Typically, it is equal to \( (1 - double.neg.eps) \times double.base ^ double.max.exp \), but on some machines it is only the second or third largest such number, being too small by 1 or 2 units in the last digit of the significand. Normally \( 1.797693e+308 \). Note that larger unnormalized numbers can occur.

double.base  the radix for the floating-point representation: normally 2.

double.digits  the number of base digits in the floating-point significand: normally 53.

double.rounding  the rounding action, one of
0 if floating-point addition chops;
1 if floating-point addition rounds, but not in the IEEE style;
2 if floating-point addition rounds in the IEEE style;
3 if floating-point addition chops, and there is partial underflow;
4 if floating-point addition rounds, but not in the IEEE style, and there is partial underflow;
5 if floating-point addition rounds in the IEEE style, and there is partial underflow.
Normally 5.

double.guard  the number of guard digits for multiplication with truncating arithmetic. It is 1 if floating-point arithmetic truncates and more than double digits base-
double.base digits participate in the post-normalization shift of the floating-point significand in multiplication, and 0 otherwise.
Normally 0.

double.ulp.digits  the largest negative integer i such that 1 + double.base ^ i != 1, except that it is bounded below by -(double.digits + 3). Normally -52.

double.neg.ulp.digits  the largest negative integer i such that 1 - double.base ^ i != 1, except that it is bounded below by -(double.digits + 3). Normally -53.

double.exponent  the number of bits (decimal places if double.base is 10) reserved for the representation of the exponent (including the bias or sign) of a floating-point number. Normally 11.

double.min.exp  the largest in magnitude negative integer i such that double.base ^ i is positive and normalized. Normally -1022.

double.max.exp  the smallest positive power of double.base that overflows. Normally 1024.

integer.max  the largest integer which can be represented. Always 2^{31} - 1 = 2147483647.

sizeof.long  the number of bytes in a C long type: 4 or 8 (most 64-bit systems, but not Windows).

sizeof.longlong  the number of bytes in a C long long type. Will be zero if there is no such type, otherwise usually 8.

sizeof.longdouble  the number of bytes in a C long double type. Will be zero if there is no such type (or its use was disabled when R was built), otherwise possibly 12 (most 32-bit builds) or 16 (most 64-bit builds).

sizeof.pointer  the number of bytes in a C SEXP type. Will be 4 on 32-bit builds and 8 on 64-bit builds of R.

Note
sizeof.longdouble only tells you the amount of storage allocated for a long double (which are normally used internally by R for accumulators in e.g. sum, and can be read by readBin). Often what is stored is the 80-bit extended double type of IEC 60559, padded to the double alignment used on the platform — this seems to be the case for the common R platforms using ix86 and x86_64 chips.

Source
Uses a C translation of Fortran code in the reference, modified by the R Core Team to defeat over-optimization in recent compilers.

## or for a neat printout
noquote(unlist(format(.Machine)))

---

."Platform  Platform Specific Variables

Description
."Platform is a list with some details of the platform under which R was built. This provides means to write OS-portable R code.

Usage
."Platform

Value
A list with at least the following components:

- **OS.type** character string, giving the Operating System (family) of the computer. One of "unix" or "windows".
- **file.sep** character string, giving the file separator used on your platform: "/" on both Unix-alikes and Windows (but not on the former port to Classic Mac OS).
- **dynlib.ext** character string, giving the file name extension of dynamically loadable libraries, e.g., ".dll" on Windows and ".so" or ".sl" on Unix-alikes. (Note for macOS users: these are shared objects as loaded by *dyn.load* and not dylibs: see *dyn.load*.)
- **GUI** character string, giving the type of GUI in use, or "unknown" if no GUI can be assumed. Possible values are for Unix-alikes the values given via the ‘-g’ command-line flag ("X11", "Tk"), "AQUA" (running under R.app on macOS), "Rgui" and "RTerm" (Windows) and perhaps others under alternative front-ends or embedded R.
- **endian** character string, "big" or "little", giving the ‘endianness’ of the processor in use. This is relevant when it is necessary to know the order to read/write bytes of e.g. an integer or double from/to a connection: see *readBin*.
- **pkgType** character string, the preferred setting for *options("pkgType")*. Values "source", "mac.binary.el-capitan" and "win.binary" are currently in use. This should not be used to identify the OS.
path.sep character string, giving the path separator, used on your platform, e.g., ":" on Unix-alikes and ";" on Windows. Used to separate paths in environment variables such as PATH and TEXINPUTS.

r_arch character string, possibly "". The name of an architecture-specific directory used in this build of R.

AQUA

.Platform$GUI is set to "AQUA" under the macOS GUI, R.app. This has a number of consequences:

- ‘/usr/local/bin’ is appended to the PATH environment variable.
- the default graphics device is set to quartz.
- selects native (rather than Tk) widgets for the graphics options of menu and select.list.
- HTML help is displayed in the internal browser.
- the spreadsheet-like data editor/viewer uses a Quartz version rather than the X11 one.

See Also

R.version and Sys.info give more details about the OS. In particular, R.version$platform is the canonical name of the platform under which R was compiled.

.Machine for details of the arithmetic used, and system for invoking platform-specific system commands.

capabilities and extSoftVersion (and links there) for availability of capabilities partly external to R but used from R functions.

Examples

```r
## Note: this can be done in a system-independent way by dir.exists()
if(.Platform$OS.type == "unix") {
  system.test <- function(...) system(paste("test", ...)) == 0L
  dir.exists2 <- function(dir)
    sapply(dir, function(d) system.test("-d", d))
  dir.exists2(c(R.home(), "/tmp", "-n", "/NO")) # > T T T F
}
```

abbreviate Abbreviate Strings

Description

Abbreviate strings to at least minlength characters, such that they remain unique (if they were), unless strict = TRUE.

Usage

```r
abbreviate(names.arg, minlength = 4, use.classes = TRUE,
           dot = FALSE, strict = FALSE,
           method = c("left.kept", "both.sides"), named = TRUE)
```
Arguments

names.arg a character vector of names to be abbreviated, or an object to be coerced to a character vector by as.character.

minlength the minimum length of the abbreviations.

use.classes logical: should lowercase characters be removed first?

dot logical: should a dot ("." ) be appended?

strict logical: should minlength be observed strictly? Note that setting strict = TRUE may return non-unique strings.

method a character string specifying the method used with default "left.kept", see 'Details' below. Partial matches allowed.

named logical: should names (with original vector) be returned.

Details

The default algorithm (method = "left.kept") used is similar to that of S. For a single string it works as follows. First spaces at the ends of the string are stripped. Then (if necessary) any other spaces are stripped. Next, lower case vowels are removed followed by lower case consonants. Finally if the abbreviation is still longer than minlength upper case letters and symbols are stripped. Characters are always stripped from the end of the strings first. If an element of names.arg contains more than one word (words are separated by spaces) then at least one letter from each word will be retained.

Missing (NA) values are unaltered.

If use.classes is FALSE then the only distinction is to be between letters and space.

Value

A character vector containing abbreviations for the character strings in its first argument. Duplicates in the original names.arg will be given identical abbreviations. If any non-duplicated elements have the same minlength abbreviations then, if method = "both.sides" the basic internal abbreviate() algorithm is applied to the characterwise reversed strings; if there are still duplicated abbreviations and if strict = FALSE as by default, minlength is incremented by one and new abbreviations are found for those elements only. This process is repeated until all unique elements of names.arg have unique abbreviations.

If names is true, the character version of names.arg is attached to the returned value as a names attribute: no other attributes are retained.

If a input element contains non-ASCII characters, the corresponding value will be in UTF-8 and marked as such (see Encoding).

Warning

If use.classes is true (the default), this is really only suitable for English, and prior to R 3.3.0 did not work correctly with non-ASCII characters in multibyte locales. It will warn if used with non-ASCII characters (and required to reduce the length).

As from R 3.3.0 the concept of 'vowel' is extended from English vowels by including characters which are accented versions of lower-case English vowels (including 'o with stroke'). Of course, there are languages (even Western European languages such as Welsh) with other vowels.

substr.
Examples

```r
x <- c("abcd", "efgh", "abce")
abbreviate(x, 2)
abbreviate(x, 2, strict = TRUE) # >> 1st and 3rd are "ab"

(st.abb <- abbreviate(state.name, 2))
stopifnot(identical(unname(st.abb),
                   abbreviate(state.name, 2, named=FALSE)))
table(nchar(st.abb)) # out of 50, 3 need 4 letters :
as <- abbreviate(state.name, 3, strict = TRUE)
as[which(as == "Mss")]

## and without distinguishing vowels:
st.abb2 <- abbreviate(state.name, 2, FALSE)
cbind(st.abb, st.abb2)[st.abb2 != st.abb, ]

## method = "both.sides" helps: no 4-letters, and only 4 3-letters:
st.ab2 <- abbreviate(state.name, 2, method = "both")
table(nchar(st.ab2))
## Compare the two methods:
cbind(st.abb, st.ab2)
```

agrep

**Approximate String Matching (Fuzzy Matching)**

Description

Searches for approximate matches to `pattern` (the first argument) within each element of the string `x` (the second argument) using the generalized Levenshtein edit distance (the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another).

Usage

```r
agrep(pattern, x, max.distance = 0.1, costs = NULL,
      ignore.case = FALSE, value = FALSE, fixed = TRUE,
      useBytes = FALSE)
agrepl(pattern, x, max.distance = 0.1, costs = NULL,
       ignore.case = FALSE, fixed = TRUE, useBytes = FALSE)
```

Arguments

- `pattern` a non-empty character string or a character string containing a regular expression (for `fixed` = `FALSE`) to be matched. Coerced by `as.character` to a string if possible.
- `x` character vector where matches are sought. Coerced by `as.character` to a character vector if possible.
- `max.distance` Maximum distance allowed for a match. Expressed either as integer, or as a fraction of the `pattern` length times the maximal transformation cost (will be replaced by the smallest integer not less than the corresponding fraction), or a list with possible components
cost: maximum number/fraction of match cost (generalized Levenshtein distance)
all: maximal number/fraction of all transformations (insertions, deletions and substitutions)
insertions: maximum number/fraction of insertions
deletions: maximum number/fraction of deletions
substitutions: maximum number/fraction of substitutions
If cost is not given, all defaults to 10%, and the other transformation number bounds default to all. The component names can be abbreviated.
costs a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the generalized Levenshtein distance, or NULL (default) indicating using unit cost for all three possible transformations. Coerced to integer via as.integer if possible.
ignore.case if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.
value if FALSE, a vector containing the (integer) indices of the matches determined is returned and if TRUE, a vector containing the matching elements themselves is returned.
fixed logical. If TRUE (default), the pattern is matched literally (as is). Otherwise, it is matched as a regular expression.
useBytes logical. in a multibyte locale, should the comparison be character-by-character (the default) or byte-by-byte.

details
The Levenshtein edit distance is used as measure of approximateness: it is the (possibly cost-weighted) total number of insertions, deletions and substitutions required to transform one string into another.
This uses tre by Ville Laurikari (http://laurikari.net/tre/), which supports MBCS character matching.
The main effect of useBytes is to avoid errors/warnings about invalid inputs and spurious matches in multibyte locales. It inhibits the conversion of inputs with marked encodings, and is forced if any input is found which is marked as "bytes" (see Encoding).

value
agrep returns a vector giving the indices of the elements that yielded a match, or, if value is TRUE, the matched elements (after coercion, preserving names but no other attributes).
agrepl returns a logical vector.

Note
Since someone who read the description carelessly even filed a bug report on it, do note that this matches substrings of each element of x (just as grep does) and not whole elements. See also adist in package utils, which optionally returns the offsets of the matched substrings.

Author(s)
Original version in R < 2.10.0 by David Meyer. Current version by Brian Ripley and Kurt Hornik.

Examples

agrep("lazy", "lasy")
agrep("lazy", c(" lasy 2", " lasy 2"), max = list(sub = 0))
agrep("laysy", c(" l lazy", "l", " l LAZY"), max = 2)
agrep("laysy", c(" l lazy", "l", " l LAZY"), max = 2, value = TRUE)
agrep("laysy", c(" l lazy", "l", " l LAZY"), max = 2, ignore.case = TRUE)

all Are All Values True?

Description

Given a set of logical vectors, are all of the values true?

Usage

all(..., na.rm = FALSE)

Arguments

... zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.

na.rm logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the Summary group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as this is often unintentional.

This is a primitive function.

Value

The value is a logical vector of length one.

Let x denote the concatenation of all the logical vectors in ... (after coercion), after removing NAs if requested by na.rm = TRUE.

The value returned is TRUE if all of the values in x are TRUE (including if there are no values), and FALSE if at least one of the values in x is FALSE. Otherwise the value is NA (which can only occur if na.rm = FALSE and ... contains no FALSE values and at least one NA value).

S4 methods

This is part of the S4 Summary group generic. Methods for it must use the signature x, ..., na.rm.
Note

That all(logical(0)) is true is a useful convention: it ensures that

all(all(x), all(y)) == all(x, y)

even if x has length zero.

References

See Also

`any`, the ‘complement’ of all, and `stopifnot()` which is an all(*) ‘insurance’.

Examples

```r
range(x <- sort(round(stats::rnorm(10) - 1.2, 1)))
if(all(x < 0)) cat("all x values are negative\n")

all(logical(0)) # true, as all zero of the elements are true.
```

---

**all.equal**

Test if Two Objects are (Nearly) Equal

Description

all.equal(x, y) is a utility to compare R objects x and y testing ‘near equality’. If they are
different, comparison is still made to some extent, and a report of the differences is returned. Do not
use all.equal directly in if expressions—either use isTRUE(all.equal(....)) or identical
if appropriate.

Usage

```r
all.equal(target, current, ...)
```

## Examples

```r
## S3 method for class 'numeric'
all.equal(target, current, 
          tolerance = sqrt(.Machine$double.eps), scale = NULL, 
          ..., check.attributes = TRUE)
```

## S3 method for class 'list'
all.equal(target, current, ..., 
          check.attributes = TRUE, use.names = TRUE)

## S3 method for class 'environment'
all.equal(target, current, all.names=TRUE, ...)

## S3 method for class 'POSIXt'
all.equal(target, current, ..., tolerance = 1e-3, scale)
```
attr.all.equal(target, current, ..., 
           check.attributes = TRUE, check.names = TRUE)

Arguments

target  R object.
current other R object, to be compared with target.
...  Further arguments for different methods, notably the following two, for numerical comparison:
tolerance numeric ≥ 0. Differences smaller than tolerance are not reported. The default value is close to 1.5e-8.
scale numeric scalar > 0 (or NULL). See ‘Details’.
check.attributes logical indicating if the attributes of target and current (other than the names) should be compared.
use.names logical indicating if list comparison should report differing components by name (if matching) instead of integer index. Note that this comes after ... and so must be specified by its full name.
all.names logical passed to ls indicating if “hidden” objects should also be considered in the environments.
check.names logical indicating if the names(.) of target and current should be compared.

Details

all.equal is a generic function, dispatching methods on the target argument. To see the available methods, use methods("all.equal"), but note that the default method also does some dispatching, e.g. using the raw method for logical targets.

Remember that arguments which follow ... must be specified by (unabbreviated) name. It is inadvisable to pass unnamed arguments in ... as these will match different arguments in different methods.

Numerical comparisons for scale = NULL (the default) are typically on relative difference scale unless the target values are close to zero: First, the mean absolute difference of the two numerical vectors is computed. If this is smaller than tolerance or not finite, absolute differences are used, otherwise relative differences scaled by the mean absolute target value. (Note that these comparisons are computed only for those vector elements where target is not NA and differs from current.)

If scale is positive, absolute comparisons are made after scaling (dividing) by scale.

For complex target, the modulus (Mod) of the difference is used: all.equal.numeric is called so arguments tolerance and scale are available.

The list method compares components of target and current recursively, passing all other arguments, as long as both are “list-like”, i.e., fulfill either is.vector or is.list.

The environment method works via the list method, and is also used for reference classes (unless a specific all.equal method is defined).

The methods for the date-time classes by default allow a tolerance of tolerance = 0.001 seconds, and ignore scale.

attr.all.equal is used for comparing attributes, returning NULL or a character vector.
Value

Either TRUE (NULL for attr.all.equal) or a vector of mode "character" describing the differences between target and current.

References

See Also

`identical`, `isTRUE`, `==`, and `all` for exact equality testing.

Examples

```r
all.equal(pi, 355/113)
# not precise enough (default tol) > relative error

d45 <- pi*(1/4 + 1:10)
stopifnot(
  all.equal(tan(d45), rep(1, 10))) # TRUE, but
  all  (tan(d45) == rep(1, 10)) # FALSE, since not exactly
  all.equal(tan(d45), rep(1, 10), tolerance = 0) # to see difference

## advanced: equality of environments
ae <- all.equal(as.environment("package:stats"),
  asNamespace("stats"))
stopifnot(is.character(ae), length(ae) > 10,
  ## were incorrectly "considered equal" in R <= 3.1.1
  all.equal(asNamespace("stats"), asNamespace("stats")))
```

**all.names**

Find All Names in an Expression

Description

Return a character vector containing all the names which occur in an expression or call.

Usage

```r
all.names(expr, functions = TRUE, max.names = -1L, unique = FALSE)
all.vars(expr, functions = FALSE, max.names = -1L, unique = TRUE)
```

Arguments

- **expr**: an expression or call from which the names are to be extracted.
- **functions**: a logical value indicating whether function names should be included in the result.
- **max.names**: the maximum number of names to be returned. -1 indicates no limit (other than vector size limits).
- **unique**: a logical value which indicates whether duplicate names should be removed from the value.
Details

These functions differ only in the default values for their arguments.

Value

A character vector with the extracted names.

See Also

substitute to replace symbols with values in an expression.

Examples

all.names(expression(sin(x+y)))
all.names(quote(sin(x+y))) # or a call
all.vars(expression(sin(x+y)))

Description

Given a set of logical vectors, is at least one of the values true?

Usage

any(..., na.rm = FALSE)

Arguments

... zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.

na.rm logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the Summary group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as this is often unintentional.

This is a primitive function.

Value

The value is a logical vector of length one.

Let x denote the concatenation of all the logical vectors in ... (after coercion), after removing NAs if requested by na.rm = TRUE.

The value returned is TRUE if at least one of the values in x is TRUE, and FALSE if all of the values in x are FALSE (including if there are no values). Otherwise the value is NA (which can only occur if na.rm = FALSE and ... contains no TRUE values and at least one NA value).
S4 methods

This is part of the S4 `summary` group generic. Methods for it must use the signature `x, ..., na.rm`.

if(any(x < 0)) cat("x contains negative values\n")
```

---

**aperm**

**Array Transposition**

Description

Transpose an array by permuting its dimensions and optionally resizing it.

Usage

```r
aperm(a, perm, ...)  
## Default S3 method:  
aperm(a, perm = NULL, resize = TRUE, ...)  
## S3 method for class 'table'  
aperm(a, perm = NULL, resize = TRUE, keep.class = TRUE, ...)
```

Arguments

- `a` the array to be transposed.
- `perm` the subscript permutation vector, usually a permutation of the integers `1:n`, where `n` is the number of dimensions of `a`. When `a` has named dimnames, it can be a character vector of length `n` giving a permutation of those names. The default (used whenever `perm` has zero length) is to reverse the order of the dimensions.
- `resize` a flag indicating whether the vector should be resized as well as having its elements reordered (default `TRUE`).
- `keep.class` logical indicating if the result should be of the same class as `a`.
- `...` potential further arguments of methods.

Value

A transposed version of array `a`, with subscripts permuted as indicated by the array `perm`. If `resize` is `TRUE`, the array is reshaped as well as having its elements permuted, the dimnames are also permuted; if `resize = FALSE` then the returned object has the same dimensions as `a`, and the dimnames are dropped. In each case other attributes are copied from `a`.

The function `t` provides a faster and more convenient way of transposing matrices.
Author(s)
Jonathan Rougier, <J.C.Rougier@durham.ac.uk> did the faster C implementation.

References

See Also
t, to transpose matrices.

Examples
```r
# interchange the first two subscripts on a 3-way array x
x <- array(1:24, 2:4)
x[,2] <- aperm(x[,2:4])
stopifnot(t(x[,2]) == x[,2],
        t(x[,3]) == x[,3],
        t(x[,4]) == x[,4])

UCB <- aperm(UCBAdmissions, c(2,1,3))
UCB[1,] # x[1,] is still a continency table
```

Description
Add elements to a vector.

Usage
```r
append(x, values, after = length(x))
```

Arguments
- `x` the vector the values are to be appended to.
- `values` to be included in the modified vector.
- `after` a subscript, after which the values are to be appended.

Value
A vector containing the values in `x` with the elements of `values` appended after the specified element of `x`.

References
Examples

```r
append(1:5, 0:1, after = 3)
```

---

**apply**

*Apply Functions Over Array Margins*

**Description**

Returns a vector or array or list of values obtained by applying a function to margins of an array or matrix.

**Usage**

```r
apply(X, MARGIN, FUN, ...)
```

**Arguments**

- `X`: an array, including a matrix.
- `MARGIN`: a vector giving the subscripts which the function will be applied over. E.g., for a matrix 1 indicates rows, 2 indicates columns, c(1, 2) indicates rows and columns. Where X has named dimnames, it can be a character vector selecting dimension names.
- `FUN`: the function to be applied: see ‘Details’. In the case of functions like +, %*%, etc., the function name must be backquoted or quoted.
- `...`: optional arguments to FUN.

**Details**

If X is not an array but an object of a class with a non-null `dim` value (such as a data frame), apply attempts to coerce it to an array via `as.matrix` if it is two-dimensional (e.g., a data frame) or via `as.array`.

`FUN` is found by a call to `match.fun` and typically is either a function or a symbol (e.g., a backquoted name) or a character string specifying a function to be searched for from the environment of the call to apply.

Arguments in ... cannot have the same name as any of the other arguments, and care may be needed to avoid partial matching to MARGIN or FUN. In general-purpose code it is good practice to name the first three arguments if ... is passed through: this both avoids partial matching to MARGIN or FUN and ensures that a sensible error message is given if arguments named X, MARGIN or FUN are passed through ....

**Value**

If each call to FUN returns a vector of length n, then apply returns an array of dimension c(n, dim(X)[MARGIN]) if n > 1. If n equals 1, apply returns a vector if MARGIN has length 1 and an array of dimension dim(X)[MARGIN] otherwise. If n is 0, the result has length 0 but not necessarily the ‘correct’ dimension.

If the calls to FUN return vectors of different lengths, apply returns a list of length `prod(dim(X)[MARGIN])` with dim set to MARGIN if this has length greater than one.

In all cases the result is coerced by `as.vector` to one of the basic vector types before the dimensions are set, so that (for example) factor results will be coerced to a character array.

Examples

```r
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
dimnames(x)[[1]] <- letters[1:8]
apply(x, 2, mean, trim = .2)
col.sums <- apply(x, 2, sum)
row.sums <- apply(x, 1, sum)
rbind(cbind(x, Rtot = row.sums), Ctot = c(col.sums, sum(col.sums)))

stopifnot( apply(x, 2, is.vector))
## Sort the columns of a matrix
apply(x, 2, sort)
## keeping named dimnames
names(dimnames(x)) <- c("row", "col")
x3 <- array(x, dim = c(dim(x),3),
    dimnames = c(dimnames(x), list(C = paste0("cop.",1:3))))
identical(x, apply( x, 2, identity))
identical(x3, apply(x3, 2:3, identity))

##- function with extra args:
cave <- function(x, c1, c2) c(mean(x[c1]), mean(x[c2]))
apply(x, 1, cave, c1 = "x1", c2 = c("x1","x2"))

ma <- matrix(c(1:4, 1, 6:8), nrow = 2)
ma
apply(ma, 1, table)  #--> a list of length 2
apply(ma, 1, stats::quantile) # 5 x n matrix with rownames

stopifnot(dim(ma) == dim(apply(ma, 1:2, sum)))

## Example with different lengths for each call
z <- array(1:24, dim = 2:4)
zseq <- apply(z, 1:2, function(x) seq_len(max(x)))
zseq 
## a 2 x 3 matrix
typeof(zseq) # list
dim(zseq) # 2 3
zseq[1,]
apply(z, 3, function(x) seq_len(max(x)))
# a list without a dim attribute
```

---

**args**

*Argument List of a Function*
Description
Displays the argument names and corresponding default values of a function or primitive.

Usage
args(name)

Arguments
name a function (a closure or a primitive). If name is a character string then the function with that name is found and used.

Details
This function is mainly used interactively to print the argument list of a function. For programming, consider using formals instead.

Value
For a closure, a closure with identical formal argument list but an empty (NULL) body.
For a primitive, a closure with the documented usage and NULL body. Note that some primitives do not make use of named arguments and match by position rather than name.
NULL in case of a non-function.

References

See Also
formals, help; str also prints the argument list of a function.

Examples
## "regular" (non-primitive) functions "print their arguments"
## (by returning another function with NULL body which you also see):
args(ls)
args(graphics::plot.default)
utils::str(ls) # (just "prints": does not show a NULL)

## You can also pass a string naming a function.
args("scan")
## ...but :: package specification doesn't work in this case.
tryCatch(args("graphics::plot.default"), error = print)

## As explained above, args() gives a function with empty body:
list(is.f = is.function(args(scan)), body = body(args(scan)))

## Primitive functions mostly behave like non-primitive functions.
args(c)
args("+"
## primitive functions without well-defined argument list return NULL:
args("if")
Description

These unary and binary operators perform arithmetic on numeric or complex vectors (or objects which can be coerced to them).

Usage

+ x
- x
x + y
x - y
x * y
x / y
x ^ y
x %% y
x %/% y

Arguments

x, y

tNumeric or complex vectors or objects which can be coerced to such, or other objects for which methods have been written.

Details

The unary and binary arithmetic operators are generic functions: methods can be written for them individually or via the Ops group generic function. (See Ops for how dispatch is computed.)

If applied to arrays the result will be an array if this is sensible (for example it will not if the recycling rule has been invoked).

Logical vectors will be coerced to integer or numeric vectors, FALSE having value zero and TRUE having value one.

1 ^ y and y ^ 0 are 1, always. x ^ y should also give the proper limit result when either (numeric) argument is infinite (one of Inf or ~Inf).

Objects such as arrays or time-series can be operated on this way provided they are conformable.

For double arguments, %% can be subject to catastrophic loss of accuracy if x is much larger than y, and a warning is given if this is detected.

%% and x %/% y can be used for non-integer y, e.g. 1 %/% 0.2, but the results are subject to representation error and so may be platform-dependent. Because the IEC 60059 representation of 0.2 is a binary fraction slightly larger than 0.2, the answer to 1 %/% 0.2 should be 4 but most platforms give 5.

Users are sometimes surprised by the value returned, for example why (-8)^(1/3) is NaN. For double inputs, R makes use of IEC 60559 arithmetic on all platforms, together with the C system function ‘pow’ for the ^ operator. The relevant standards define the result in many corner cases. In particular, the result in the example above is mandated by the C99 standard. On many Unix-alike systems the command man pow gives details of the values in a large number of corner cases.

Arithmetic on type double in R is supposed to be done in ‘round to nearest, ties to even’ mode, but this does depend on the compiler and FPU being set up correctly.
Value

Unary + and unary - return a numeric or complex vector. All attributes (including class) are preserved if there is no coercion: logical x is coerced to integer and names, dims and dimnames are preserved.

The binary operators return vectors containing the result of the element by element operations. If involving a zero-length vector the result has length zero. Otherwise, the elements of shorter vectors are recycled as necessary (with a warning when they are recycled only fractionally). The operators are + for addition, - for subtraction, * for multiplication, / for division and ^ for exponentiation.

%% indicates x mod y and %/% indicates integer division. It is guaranteed that x == (x %% y) + y * (x %/% y) (up to rounding error) unless y == 0 where the result of %% is NA_integer_ or NaN (depending on the typeof of the arguments), and for non-finite arguments.

If either argument is complex the result will be complex, otherwise if one or both arguments are numeric, the result will be numeric. If both arguments are of type integer, the type of the result of / and ^ is numeric and for the other operators it is integer (with overflow, which occurs at ±(2^{31} − 1), returned as NA_integer_ with a warning).

The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. If the arguments are the same length, attributes will be copied from both, with those of the first argument taking precedence when the same attribute is present in both arguments. For time series, these operations are allowed only if the series are compatible, when the class and tsp attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

S4 methods

These operators are members of the S4 Arith group generic, and so methods can be written for them individually as well as for the group generic (or the Ops group generic), with arguments c(e1, e2) (with e2 missing for a unary operator).

Implementation limits

R is dependent on OS services (and they on FPUs) for floating-point arithmetic. On all current R platforms IEC 60559 (also known as IEEE 754) arithmetic is used, but some things in those standards are optional. In particular, the support for denormal numbers (those outside the range given by .Machine) may differ between platforms and even between calculations on a single platform.

Another potential issue is signed zeroes: on IEC 60659 platforms there are two zeroes with internal representations differing by sign. Where possible R treats them as the same, but for example direct output from C code often does not do so and may output ‘-0.0’ (and on Windows whether it does so or not depends on the version of Windows). One place in R where the difference might be seen is in division by zero: 1/x is Inf or -Inf depending on the sign of zero x. Another place is identical(0, -0, num.eq = FALSE).

Note

All logical operations involving a zero-length vector have a zero-length result.

The binary operators are sometimes called as functions as e.g. `&`(x, y): see the description of how argument-matching is done in Ops.

** is translated in the parser to ^, but this was undocumented for many years. It appears as an index entry in Becker et al (1988), pointing to the help for Deprecated but is not actually mentioned on that page. Even though it had been deprecated in S for 20 years, it was still accepted in R in 2008.

x <- -1:12
x + 1
2 * x + 3
x %% 2 #-- is periodic
x %/% 5
```

---

**array**

Multi-way Arrays

Description

Creates or tests for arrays.

Usage

```r
array(data = NA, dim = length(data), dimnames = NULL)
as.array(x, ...)
is.array(x)
```

Arguments

- `data` a vector (including a list or `expression` vector) giving data to fill the array. Non-atomic classed objects are coerced by `as.vector`.
- `dim` the dim attribute for the array to be created, that is an integer vector of length one or more giving the maximal indices in each dimension.
- `dimnames` either `NULL` or the names for the dimensions. This must a list (or it will be ignored) with one component for each dimension, either `NULL` or a character vector of the length given by `dim` for that dimension. The list can be named, and the list names will be used as names for the dimensions. If the list is shorter than the number of dimensions, it is extended by `NULL`s to the length required.
- `x` an R object.
- `...` additional arguments to be passed to or from methods.
Details

An array in R can have one, two or more dimensions. It is simply a vector which is stored with additional attributes giving the dimensions (attribute "dim") and optionally names for those dimensions (attribute "dimnames").

A two-dimensional array is the same thing as a matrix.

One-dimensional arrays often look like vectors, but may be handled differently by some functions: str does distinguish them in recent versions of R.

The "dim" attribute is an integer vector of length one or more containing non-negative values: the product of the values must match the length of the array.

The "dimnames" attribute is optional: if present it is a list with one component for each dimension, either NULL or a character vector of the length given by the element of the "dim" attribute for that dimension.

is.array is a primitive function.

For a list array, the print methods prints entries of length not one in the form ‘integer,7’ indicating the type and length.

Value

array returns an array with the extents specified in dim and naming information in dimnames. The values in data are taken to be those in the array with the leftmost subscript moving fastest. If there are too few elements in data to fill the array, then the elements in data are recycled. If data has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.

Unlike matrix, array does not currently remove any attributes left by as.vector from a classed list data, so can return a list array with a class attribute.

as.array is a generic function for coercing to arrays. The default method does so by attaching a dim attribute to it. It also attaches dimnames if x has names. The sole purpose of this is to make it possible to access the dim[names] attribute at a later time.

is.array returns TRUE or FALSE depending on whether its argument is an array (i.e., has a dim attribute of positive length) or not. It is generic: you can write methods to handle specific classes of objects, see InternalMethods.

Note

is.array is a primitive function.

Examples

dim(as.array(letters))
array(1:3, c(2,4)) # recycle 1:3 "2 2/3 times"
# [1,] 1 2 1 2
# [2,] 3 4 3 4
as.data.frame

Coerce to a Data Frame

Description

Functions to check if an object is a data frame, or coerce it if possible.

Usage

as.data.frame(x, row.names = NULL, optional = FALSE, ...)  

## S3 method for class 'character'
as.data.frame(x, ...,  
  stringsAsFactors = default.stringsAsFactors())

## S3 method for class 'list'
as.data.frame(x, row.names = NULL, optional = FALSE, ...,  
  cut.names = FALSE, col.names = names(x), fix.empty.names = TRUE,  
  stringsAsFactors = default.stringsAsFactors())

## S3 method for class 'matrix'
as.data.frame(x, row.names = NULL, optional = FALSE, ...,  
  stringsAsFactors = default.stringsAsFactors())

is.data.frame(x)

Arguments

x any R object.

row.names NULL or a character vector giving the row names for the data frame. Missing values are not allowed.

optional logical. If TRUE, setting row names and converting column names (to syntactic names: see make.names) is optional. Note that all of R’s base package as.data.frame() methods use optional only for column names treatment, basically with the meaning of data.frame(*, check.names = !optional).

... additional arguments to be passed to or from methods.

stringsAsFactors logical: should the character vector be converted to a factor?

cut.names logical or integer: indicating if column names with more than 256 (or cut.names if that is numeric) characters should be shortened (and the last 6 characters replaced by "...").

col.names (optional) character vector of column names.

fix.empty.names logical indicating if empty column names, i.e., "" should be fixed up (in data.frame) or not.
as.Date

Details

as.data.frame is a generic function with many methods, and users and packages can supply further methods. For classes that act as vectors, often a copy of as.data.frame.vector will work as the method.

If a list is supplied, each element is converted to a column in the data frame. Similarly, each column of a matrix is converted separately. This can be overridden if the object has a class which has a method for as.data.frame: two examples are matrices of class "model.matrix" (which are included as a single column) and list objects of class "POSIXlt" which are coerced to class "POSIXct".

Arrays can be converted to data frames. One-dimensional arrays are treated like vectors and two-dimensional arrays like matrices. Arrays with more than two dimensions are converted to matrices by ‘flattening’ all dimensions after the first and creating suitable column labels.

Character variables are converted to factor columns unless protected by I.

If a data frame is supplied, all classes preceding "data.frame" are stripped, and the row names are changed if that argument is supplied.

If row.names = NULL, row names are constructed from the names or dimnames of x, otherwise are the integer sequence starting at one. Few of the methods check for duplicated row names. Names are removed from vector columns unless I.

Value

as.data.frame returns a data frame, normally with all row names "" if optional = TRUE.

is.data.frame returns TRUE if its argument is a data frame (that is, has "data.frame" amongst its classes) and FALSE otherwise.

References

See Also
data.frame, as.data.frame.table for the table method (which has additional arguments if called directly).

as.Date  

Date Conversion Functions to and from Character

Description

Functions to convert between character representations and objects of class "date" representing calendar dates.
as.Date

Usage

as.Date(x, ...)
## S3 method for class 'character'
as.Date(x, format, tryFormats = c("%Y-%m-%d", "%Y/%m/%d"),
onoptional = FALSE, ...)
## S3 method for class 'numeric'
as.Date(x, origin, ...)
## S3 method for class 'POSIXct'
as.Date(x, tz = "UTC", ...)

## S3 method for class 'Date'
format(x, ...)

## S3 method for class 'Date'
as.character(x, ...)

Arguments

x
an object to be converted.

format character string. If not specified, it will try tryFormats one by one on the first non-NA element, and give an error if none works. Otherwise, the processing is via strptime.

tryFormats character vector of format strings to try if format is not specified.

optional logical indicating to return NA (instead of signalling an error) if the format guessing does not succeed.

origin a Date object, or something which can be coerced by as.Date(origin, ...) to such an object.

tz a time zone name.

... further arguments to be passed from or to other methods, including format for as.character and as.Date methods.

Details

The usual vector re-cycling rules are applied to x and format so the answer will be of length that of the longer of the vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months.

The as.Date methods accept character strings, factors, logical NA and objects of classes "POSIXt" and "POSIXct". (The last is converted to days by ignoring the time after midnight in the representation of the time in specified time zone, default UTC.) Also objects of class "date" (from package date) and "dates" (from package chron). Character strings are processed as far as necessary for the format specified: any trailing characters are ignored.

as.Date will accept numeric data (the number of days since an epoch), but only if origin is supplied.

The format and as.character methods ignore any fractional part of the date.
Value

The format and as.character methods return a character vector representing the date. NA dates are returned as NA_character_.

The as.Date methods return an object of class "Date".

Conversion from other Systems

Most systems record dates internally as the number of days since some origin, but this is fraught with problems, including

- Is the origin day 0 or day 1? As the ‘Examples’ show, Excel manages to use both choices for its two date systems.
- If the origin is far enough back, the designers may show their ignorance of calendar systems. For example, Excel’s designer thought 1900 was a leap year (claiming to copy the error from earlier DOS spreadsheets), and Matlab’s designer chose the non-existent date of ‘January 0, 0000’ (there is no such day), not specifying the calendar. (There is such a year in the ‘Gregorian’ calendar as used in ISO 8601:2004, but that does say that it is only to be used for years before 1582 with the agreement of the parties in information exchange.)

The only safe procedure is to check the other systems values for known dates: reports on the Internet (including R-help) are more often wrong than right.

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-03".

If the date string does not specify the date completely, the returned answer may be system-specific. The most common behaviour is to assume that a missing year, month or day is the current one. If it specifies a date incorrectly, reliable implementations will give an error and the date is reported as NA. Unfortunately some common implementations (such as ‘glibc’) are unreliable and guess at the intended meaning.

Years before 1CE (aka 1AD) will probably not be handled correctly.

References

See Also

Date for details of the date class; locales to query or set a locale.

Your system’s help pages on strftime and strptime to see how to specify their formats. Windows users will find no help page for strftime: code based on ‘glibc’ is used (with corrections), so all the format specifiers described here are supported, but with no alternative number representation nor era available in any locale.

Examples

## locale-specific version of the date
format(Sys.Date(), "%a %b %d")
## read in date info in format 'ddmmyyyy'
This will give NA(s) in some locales; setting the C locale
as in the commented lines will overcome this on most systems.
lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- as.Date(x, "%d%b%Y")
## read in date/time info in format 'm/d/y'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
as.Date(dates, "%m/%d/%y")
## date given as number of days since 1900-01-01 (a date in 1989)
as.Date(32768, origin = "1900-01-01")
## Excel is said to use 1900-01-01 as day 1 (Windows default) or
## 1904-01-01 as day 0 (Mac default), but this is complicated by Excel
## incorrectly treating 1900 as a leap year.
## So for dates (post-1901) from Windows Excel
as.Date(35981, origin = "1899-12-30") # 1998-07-05
## and Mac Excel
as.Date(34519, origin = "1904-01-01") # 1998-07-05
## (these values come from http://support.microsoft.com/kb/214330)
## Experiment shows that Matlab's origin is 719529 days before ours,
## (it takes the non-existent 0000-01-01 as day 1)
## so Matlab day 734373 can be imported as
as.Date(734373, origin = "1970-01-01") - 719529 # 2010-08-23
## (value from
## Time zone effect
z <- ISOdate(2010, 04, 13, c(0,12)) # midnight and midday UTC
as.Date(z) # in UTC
## these time zone names are common
as.Date(z, tz = "NZ")
as.Date(z, tz = "HST") # Hawaii

---

**as.environment**  
*Coerce to an Environment Object*

### Description
A generic function coercing an R object to an environment. A number or a character string is converted to the corresponding environment on the search path.

### Usage

```r
as.environment(x)
```

### Arguments

- `x`  
an R object to convert. If it is already an environment, just return it. If it is a positive number, return the environment corresponding to that position on the
as.function

Convert Object to Function

Description
as.function is a generic function which is used to convert objects to functions.
as.function.default works on a list x, which should contain the concatenation of a formal argument list and an expression or an object of mode "call" which will become the function body. The function will be defined in a specified environment, by default that of the caller.

Usage
as.function(x, ...)  

## Default S3 method:  
as.function(x, envir = parent.frame(), ...)
as.POSIX*

Arguments

x  object to convert, a list for the default method.
...
envir  environment in which the function should be defined

Value

The desired function.

Note

For ancient historical reasons, envir = NULL uses the global environment rather than the base environment. Please use envir = globalenv() instead if this is what you want, as the special handling of NULL may change in a future release.

Author(s)

Peter Dalgaard

See Also

function; alist which is handy for the construction of argument lists, etc.

Examples

as.function(alist(a = , b = 2, a+b))
as.function(alist(a = , b = 2, a+b))(3)

---

Date-time Conversion Functions

Description

Functions to manipulate objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

as.POSIXct(x, tz = "", ...)  
as.POSIXlt(x, tz = "", ...)  

## S3 method for class 'character'
as.POSIXlt(x, tz = "", format,
  tryFormats = c("%Y-%m-%d %H:%M:%OS",
    "%Y/%m/%d %H:%M:%OS",
    "%Y-%m-%d %H:%M",
    "%Y/%m/%d %H:%M",
    "%Y-%m-%d",
    "%Y/%m/%d"),
  optional = FALSE, ...)  

## Default S3 method:

---

as.POSIXct
as.POSIX*

as.POSIXlt(x, tz = "", optional = FALSE, ...)
## S3 method for class 'numeric'
as.POSIXlt(x, tz = "", origin, ...)
## S3 method for class 'POSIXlt'
as.double(x, ...)

Arguments

x
R object to be converted.

tz
time zone specification to be used for the conversion, if one is required. System-specific (see time zones), but "" is the current time zone, and "GMT" is UTC (Universal Time, Coordinated). Invalid values are most commonly treated as UTC, on some platforms with a warning.

...
further arguments to be passed to or from other methods.

format
character string giving a date-time format as used by 

tryFormats
character vector of format strings to try if format is not specified.

optional
logical indicating to return NA (instead of signalling an error) if the format guessing does not succeed.

origin
a date-time object, or something which can be coerced by as.POSIXct(tz = "GMT") to such an object.

Details

The as.POSIX* functions convert an object to one of the two classes used to represent date/times (calendar dates plus time to the nearest second). They can convert a wide variety of objects, including objects of the other class and of classes "Date", "date" (from package date), "chron" and "dates" (from package chron) to these classes. Dates without times are treated as being at midnight UTC.

They can also convert character strings of the formats "2001-02-03" and "2001/02/03" optionally followed by white space and a time in the format "14:52" or "14:52:03". (Formats such as "01/02/03" are ambiguous but can be converted via a format specification by strptime.) Fractional seconds are allowed. Alternatively, format can be specified for character vectors or factors: if it is not specified and no standard format works for all non-NA inputs an error is thrown.

If format is specified, remember that some of the format specifications are locale-specific, and you may need to set the LC_TIME category appropriately via Sys.setlocale. This most often affects the use of %b, %B (month names) and %p (AM/PM).

Logical NAs can be converted to either of the classes, but no other logical vectors can be.

If you are given a numeric time as the number of seconds since an epoch, see the examples.

Character input is first converted to class "POSIXlt" by strptime: numeric input is first converted to "POSIXct". Any conversion that needs to go between the two date-time classes requires a time zone: conversion from "POSIXlt" to "POSIXct" will validate times in the selected time zone. One issue is what happens at transitions to and from DST, for example in the UK

as.POSIXct(strptime("2011-03-27 01:30:00", "%Y-%m-%d %H:%M:%S"))
as.POSIXct(strptime("2010-10-31 01:30:00", "%Y-%m-%d %H:%M:%S"))
are respectively invalid (the clocks went forward at 1:00 GMT to 2:00 BST) and ambiguous (the
clocks went back at 2:00 BST to 1:00 GMT). What happens in such cases is OS-specific: one should
expect the first to be \code{NA}, but the second could be interpreted as either BST or GMT (and common
OSes give both possible values). Note too (see \code{strftime}) that OS facilities may not format invalid
times correctly.

\section*{Value}

\code{as.POSIXct} and \code{as.POSIXlt} return an object of the appropriate class. If \code{tz} was specified,
\code{as.POSIXlt} will give an appropriate \code{tzone} attribute. Date-times known to be invalid will be
returned as \code{NA}.

\section*{Note}

Some of the concepts used have to be extended backwards in time (the usage is said to be 'pro-
leptic'). For example, the origin of time for the \code{"POSIXct"} class, \code{"1970-01-01 00:00.00 UTC"},
is before UTC was defined. More importantly, conversion is done assuming the Gregorian cal-
endar which was introduced in 1582 and not used universally until the 20th century. One of
the re-interpretations assumed by ISO 8601:2004 is that there was a year zero, even though current
year numbering (and zero) is a much later concept (525 AD for year numbers from 1 AD).

If you want to extract specific aspects of a time (such as the day of the week) just convert it to class
\code{"POSIXlt"} and extract the relevant component(s) of the list, or if you want a character representa-
tion (such as a named day of the week) use the \code{format} method.

If a time zone is needed and that specified is invalid on your system, what happens is system-specific
but attempts to set it will probably be ignored.

Conversion from character needs to find a suitable format unless one is supplied (by trying common
formats in turn): this can be slow for long inputs.

\section*{Examples}

\begin{example}
\begin{Schunk}
\begin{Sinput}
(z <- Sys.time()) # the current datetime, as class "POSIXct"
unclass(z) # a large integer
floor(unclass(z)/86400) # the number of days since 1970-01-01 (UTC)
(now <- as.POSIXlt(Sys.time())) # the current datetime, as class "POSIXlt"
unlist(unclass(now)) # a list shown as a named vector
now$year + 1900 # see \code{DateTimeClasses}
months(now); weekdays(now) # see \code{months}

## suppose we have a time in seconds since 1960-01-01 00:00:00 GMT
## (the origin used by SAS)
z <- 1472562988 # ways to convert this
as.POSIXct(z, origin = "1960-01-01") # local
as.POSIXct(z, origin = "1960-01-01", tz = "GMT") # in UTC

## SPSS dates (R-help 2006-02-16)
\end{Sinput}
\end{Schunk}
\end{example}
AsIs

Inhibit Interpretation/Conversion of Objects

Description
Change the class of an object to indicate that it should be treated 'as is'.

Usage
I(x)

Arguments
x  an object

Details
Function I has two main uses.

• In function data.frame. Protecting an object by enclosing it in I() in a call to data.frame inhibits the conversion of character vectors to factors and the dropping of names, and ensures that matrices are inserted as single columns. I can also be used to protect objects which are to be added to a data frame, or converted to a data frame via as.data.frame. It achieves this by prepending the class "AsIs" to the object’s classes. Class "AsIs" has a few of its own methods, including for [, as.data.frame, print and format.

• In function formula. There it is used to inhibit the interpretation of operators such as "+", "-", "*" and "^" as formula operators, so they are used as arithmetical operators. This is interpreted as a symbol by terms.formula.
assign
Assign a Value to a Name

Description
Assign a value to a name in an environment.

Usage
assign(x, value, pos = -1, envir = as.environment(pos),
inherits = FALSE, immediate = TRUE)

Arguments
x  a variable name, given as a character string. No coercion is done, and the first
element of a character vector of length greater than one will be used, with a
warning.
value a value to be assigned to x.
pos where to do the assignment. By default, assigns into the current environment.
See ‘Details’ for other possibilities.
envir the environment to use. See ‘Details’.
inherits should the enclosing frames of the environment be inspected?
immediate an ignored compatibility feature.

Details
There are no restrictions on the name given as x: it can be a non-syntactic name (see make.names).
The pos argument can specify the environment in which to assign the object in any of several
ways: as -1 (the default), as a positive integer (the position in the search list); as the character
string name of an element in the search list; or as an environment (including using sys.frame to
access the currently active function calls). The envir argument is an alternative way to specify an
environment, but is primarily for back compatibility.
assign does not dispatch assignment methods, so it cannot be used to set elements of vectors,
names, attributes, etc.
Note that assignment to an attached list or data frame changes the attached copy and not the original
object: see attach and with.

Value
A copy of the object with class "AsIs" prepended to the class(es).

References

See Also
data.frame, formula
Value

This function is invoked for its side effect, which is assigning value to the variable \( x \). If no \( \text{envir} \) is specified, then the assignment takes place in the currently active environment.

If \( \text{inherits} \) is TRUE, enclosing environments of the supplied environment are searched until the variable \( x \) is encountered. The value is then assigned in the environment in which the variable is encountered (provided that the binding is not locked: see \text{lockBinding}; if it is, an error is signaled). If the symbol is not encountered then assignment takes place in the user’s workspace (the global environment).

If \( \text{inherits} \) is FALSE, assignment takes place in the initial frame of \( \text{envir} \), unless an existing binding is locked or there is no existing binding and the environment is locked (when an error is signaled).

References

See Also

\(<-\), \text{get}, the inverse of \text{assign()}. \text{exists}, \text{environment}.

Examples

```r
for(i in 1:6) {  #-- Create objects ‘r.1’, ‘r.2’, ... ‘r.6’ --
  nam <- paste("r", i, sep = ".")
  assign(nam, 1:i)
}
ls(pattern = "^r..$")

##-- Global assignment within a function:
myf <- function(x) {
  innerf <- function(x) assign("Global.res", x^2, envir = .GlobalEnv)
  innerf(x+1)
}
myf(3)
Global.res # 16

a <- 1:4
assign("a[1]", 2)
a[1] == 2  # FALSE
get("a[1]") == 2  # TRUE
```

assignOps

Assignment Operators

Description

Assign a value to a name.
Usage

\[
x <- value \\
\text{x <<- value} \\
\text{value -> x} \\
\text{value ->> x} \\
x = value
\]

Arguments

- **x**: a variable name (possibly quoted).
- **value**: a value to be assigned to \( x \).

Details

There are three different assignment operators: two of them have leftwards and rightwards forms.

The operators `<-` and `=` assign into the environment in which they are evaluated. The operator `<-` can be used anywhere, whereas the operator `=` is only allowed at the top level (e.g., in the complete expression typed at the command prompt) or as one of the subexpressions in a braced list of expressions.

The operators `<<-` and `->>` are normally only used in functions, and cause a search to be made through parent environments for an existing definition of the variable being assigned. If such a variable is found (and its binding is not locked) then its value is redefined, otherwise assignment takes place in the global environment. Note that their semantics differ from that in the S language, but are useful in conjunction with the scoping rules of R. See ‘The R Language Definition’ manual for further details and examples.

In all the assignment operator expressions, \( x \) can be a name or an expression defining a part of an object to be replaced (e.g., \( z[[1]] \)). A syntactic name does not need to be quoted, though it can be (preferably by backticks).

The leftwards forms of assignment `<-` = `<<-` group right to left, the other from left to right.

Value

- **value**: Thus one can use \( a <- b <- c <- 6 \).

References

See Also

- **assign** (and its inverse **get**), for “subassignment” such as \( x[1] <- v \), see `<<-`; further, **environment**.
attach

Attach Set of R Objects to Search Path

Description

The database is attached to the R search path. This means that the database is searched by R when evaluating a variable, so objects in the database can be accessed by simply giving their names.

Usage

attach(what, pos = 2L, name = deparse(substitute(what), backtick=FALSE),
    warn.conflicts = TRUE)

Arguments

what 'database'. This can be a data.frame or a list or a R data file created with save or NULL or an environment. See also ‘Details’.
pos integer specifying position in search() where to attach.
name name to use for the attached database. Names starting with package: are re-
    served for library.
warn.conflicts logical. If TRUE, warnings are printed about conflicts from attaching the
database, unless that database contains an object .conflicts.OK. A conflict
is a function masking a function, or a non-function masking a non-function.

Details

When evaluating a variable or function name R searches for that name in the databases listed by search. The first name of the appropriate type is used.

By attaching a data frame (or list) to the search path it is possible to refer to the variables in the data frame by their names alone, rather than as components of the data frame (e.g., in the example below, height rather than women$height).

By default the database is attached in position 2 in the search path, immediately after the user’s workspace and before all previously attached packages and previously attached databases. This can be altered to attach later in the search path with the pos option, but you cannot attach at pos = 1.

The database is not actually attached. Rather, a new environment is created on the search path and the elements of a list (including columns of a data frame) or objects in a save file or an environment are copied into the new environment. If you use <<- or assign to assign to an attached database, you only alter the attached copy, not the original object. (Normal assignment will place a modified version in the user’s workspace: see the examples.) For this reason attach can lead to confusion.

One useful 'trick' is to use what = NULL (or equivalently a length-zero list) to create a new environment on the search path into which objects can be assigned by assign or load or sys.source.

Names starting "package:" are reserved for library and should not be used by end users. Attached files are by default given the name file:what. The name argument given for the attached environment will be used by search and can be used as the argument to as.environment.

There are hooks to attach user-defined table objects of class "UserDefinedDatabase", supported by the Omegahat package RObjectTables. See http://www.omegahat.net/RObjectTables/.
Value

The environment is returned invisibly with a "name" attribute.

Good practice

`attach` has the side effect of altering the search path and this can easily lead to the wrong object of a particular name being found. People do often forget to `detach` databases.

In interactive use, `with` is usually preferable to the use of `attach/detach`, unless what is a `save()`-produced file in which case `attach()` is a (safety) wrapper for `load()`.

In programming, functions should not change the search path unless that is their purpose. Often `with` can be used within a function. If not, good practice is to

- Always use a distinctive name argument, and
- To immediately follow the `attach` call by an `on.exit` call to `detach` using the distinctive name.

This ensures that the search path is left unchanged even if the function is interrupted or if code after the `attach` call changes the search path.

Examples

```r
require(utils)

summary(women$height) # refers to variable 'height' in the data frame
attach(women)
summary(height) # The same variable now available by name
height <- height*2.54 # Don't do this. It creates a new variable
                   # in the user's workspace
find("height")
summary(height) # The new variable in the workspace
rm(height)
summary(height) # The original variable.
height <<- height*25.4 # Change the copy in the attached environment
find("height")
summary(height) # The changed copy
detach("women")
summary(women$height) # unchanged

## Not run: ## create an environment on the search path and populate it
sys.source("myfuns.R", envir = attach(NULL, name = "myfuns"))

## End(Not run)
```
**Description**

Get or set specific attributes of an object.

**Usage**

```r
attr(x, which, exact = FALSE)
attr(x, which) <- value
```

**Arguments**

- `x` an object whose attributes are to be accessed.
- `which` a non-empty character string specifying which attribute is to be accessed.
- `exact` logical: should `which` be matched exactly?
- `value` an object, the new value of the attribute, or `NULL` to remove the attribute.

**Details**

These functions provide access to a single attribute of an object. The replacement form causes the named attribute to take the value specified (or create a new attribute with the value given).

The extraction function first looks for an exact match to `which` amongst the attributes of `x`, then (unless `exact = TRUE`) a unique partial match. (Setting `options(warnPartialMatchAttr = TRUE)` causes partial matches to give warnings.)

The replacement function only uses exact matches.

Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set. (Note that this is not true of `levels` which should be set for factors via the `levels` replacement function.)

The extractor function allows (and does not match) empty and missing values of which: the replacement function does not.

`NULL` objects cannot have attributes and attempting to assign one by `attr` gives an error.

Both are primitive functions.

**Value**

For the extractor, the value of the attribute matched, or `NULL` if no exact match is found and no or more than one partial match is found.

**References**

**See Also**

- `attributes`
Examples

# create a 2 by 5 matrix
x <- 1:10
attr(x,"dim") <- c(2, 5)

Description

These functions access an object’s attributes. The first form below returns the object’s attribute list. The replacement forms uses the list on the right-hand side of the assignment as the object’s attributes (if appropriate).

Usage

attributes(obj)
attributes(obj) <- value
mostattributes(obj) <- value

Arguments

obj an object
value an appropriate named list of attributes, or NULL.

Details

Unlike `attr` it is possible to set attributes on a NULL object: it will first be coerced to an empty list. Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set. (Note that this is not true of `levels` which should be set for factors via the `levels` replacement function.)

Attributes are not stored internally as a list and should be thought of as a set and not a vector. They must have unique names (and `NA` is taken as "NA", not a missing value).

Assigning attributes first removes all attributes, then sets any `dim` attribute and then the remaining attributes in the order given: this ensures that setting a `dim` attribute always precedes the `dimnames` attribute.

The `mostattributes` assignment takes special care for the `dim`, `names` and `dimnames` attributes, and assigns them only when known to be valid whereas an attributes assignment would give an error if any are not. It is principally intended for arrays, and should be used with care on classed objects. For example, it does not check that `row.names` are assigned correctly for data frames.

The names of a pairlist are not stored as attributes, but are reported as if they were (and can be set by the replacement form of `attributes`).

`NULL` objects cannot have attributes and attempts to assign them will promote the object to an empty list.

Both assignment and replacement forms of `attributes` are primitive functions.

References

See Also

attr, structure.

Examples

```r
x <- cbind(a = 1:3, pi = pi) # simple matrix with dimnames
attributes(x)

## strip an object's attributes:
attributes(x) <- NULL
x # now just a vector of length 6

mostattributes(x) <- list(mycomment = "really special", dim = 3:2,
  dimnames = list(LETTERS[1:3], letters[1:5]), names = paste(1:6))
x # dim(), but not (dim)names
```
**Examples**

```r
class <- require(stats)
autoloading("interpSpline", "splines")
search()
ls("Autoloads")
  Autoloaded

x <- sort(stats::rnorm(12))
y <- x^2
is <- interpSpline(x, y)
search()  ## now has splines
detach("package:splines")
search()
is2 <- interpSpline(x, y+x)
search()  ## and again
detach("package:splines")
```

---

**backsolve**

*Solve an Upper or Lower Triangular System*

**Description**

Solves a triangular system of linear equations.

**Usage**

```r
backsolve(r, x, k = ncol(r), upper.tri = TRUE,
  transpose = FALSE)
forwardsolve(l, x, k = ncol(l), upper.tri = FALSE,
  transpose = FALSE)
```

**Arguments**

- `r`, `l`  
an upper (or lower) triangular matrix giving the coefficients for the system to be solved. Values below (above) the diagonal are ignored.
- `x`  
a matrix whose columns give the right-hand sides for the equations.
- `k`  
The number of columns of `r` and rows of `x` to use.
- `upper.tri`  
logical; if `TRUE` (default), the upper triangular part of `r` is used. Otherwise, the lower one.
- `transpose`  
logical; if `TRUE`, solve \( r' \ast y = x \) for `y`, i.e., \( t(r) \ast y \ast x \).

**Details**

Solves a system of linear equations where the coefficient matrix is upper (or ‘right’, ‘R’) or lower (‘left’, ‘L’) triangular.

- `x <- backsolve(r, b)` solves \( R_1 x = b \), and
- `x <- forwardsolve(l, b)` solves \( L_1 x = b \), respectively.

The `r/l` must have at least `k` rows and columns, and `x` must have at least `k` rows.

This is a wrapper for the level-3 BLAS routine `dtrsm`. 
Value

The solution of the triangular system. The result will be a vector if \( x \) is a vector and a matrix if \( x \) is a matrix.

References

See Also

`chol`, `qr`, `solve`.

Examples

```r
## upper triangular matrix 'r':
r <- rbind(c(1,2,3),
c(0,1,1),
c(0,0,2))
(y <- backsolve(r, x <- c(8,4,2)) ) # -1 3 1
r %*% y # == x = (8,4,2)
backsolve(r, x, transpose = TRUE) # 8 -12 -5
```

### basename

**Manipulate File Paths**

**Description**

`basename` removes all of the path up to and including the last path separator (if any).

`dirname` returns the part of the path up to but excluding the last path separator, or "." if there is no path separator.

**Usage**

```r
basename(path)
dirname(path)
```

**Arguments**

`path` character vector, containing path names.

**Details**

For `dirname`, tilde expansion of the path is done.

Trailing path separators are removed before dissecting the path, and for `dirname` any trailing file separators are removed from the result.
Value

A character vector of the same length as `path`. A zero-length input will give a zero-length output with no error.

Paths not containing any separators are taken to be in the current directory, so `dirname` returns ".".

If an element of `path` is `NA`, so is the result.

"" is not a valid pathname, but is returned unchanged.

Behaviour on Windows

On Windows this will accept either `\` or `/` as the path separator, but `dirname` will return a path using `/` (except if on a network share, when the leading `\` will be preserved). Expect these only to be able to handle complete paths, and not for example just a network share or a drive.

UTF-8-encoded path names not valid in the current locale can be used.

Note

These are not wrappers for the POSIX system functions of the same names: in particular they do not have the special handling of the path "/" and of returning "." for empty strings.

See Also

`file.path`, `path.expand`.

Examples

```r
basename(file.path("","p1","p2","p3", c("file1", "file2")))
dirname(file.path("", "p1","p2","p3","filename"))
```

---

### Bessel

**Bessel Functions**

**Description**

Bessel Functions of integer and fractional order, of first and second kind, $J_\nu$ and $Y_\nu$, and Modified Bessel functions (of first and third kind), $I_\nu$ and $K_\nu$.

**Usage**

```r
besselI(x, nu, expon.scaled = FALSE)
besselK(x, nu, expon.scaled = FALSE)
besselJ(x, nu)
besselY(x, nu)
```

**Arguments**

- `x` numeric, ≥ 0.
- `nu` numeric; The order (maybe fractional!) of the corresponding Bessel function.
- `expon.scaled` logical; if TRUE, the results are exponentially scaled in order to avoid overflow ($I_\nu$) or underflow ($K_\nu$), respectively.
Details

If \( \text{expon.scaled} = \text{TRUE} \), \( e^{-x} I_{\nu}(x) \), or \( e^{x} K_{\nu}(x) \) are returned.

For \( \nu < 0 \), formulae 9.1.2 and 9.6.2 from Abramowitz & Stegun are applied (which is probably suboptimal), except for \( \text{besselK} \) which is symmetric in \( \nu \).

The current algorithms will give warnings about accuracy loss for large arguments. In some cases, these warnings are exaggerated, and the precision is perfect. For large \( \nu \), say in the order of millions, the current algorithms are rarely useful.

Value

Numeric vector with the (scaled, if \( \text{expon.scaled} = \text{TRUE} \)) values of the corresponding Bessel function.

The length of the result is the maximum of the lengths of the parameters. All parameters are recycled to that length.

bindenv

### Binding and Environment Locking, Active Bindings

**Description**

These functions represent an interface for adjustments to environments and bindings within environments. They allow for locking environments as well as individual bindings, and for linking a variable to a function.

**Usage**

```r
lockEnvironment(env, bindings = FALSE)
environmentIsLocked(env)
lockBinding(sym, env)
unlockBinding(sym, env)
bindingIsLocked(sym, env)
makeActiveBinding(sym, fun, env)
bindingIsActive(sym, env)
```

**Arguments**

- `env` an environment.
- `bindings` logical specifying whether bindings should be locked.
- `sym` a name object or character string.
- `fun` a function taking zero or one arguments.

**Details**

The function `lockEnvironment` locks its environment argument, which must be a normal environment (not base). (Locking the base environment and namespace may be supported later.) Locking the environment prevents adding or removing variable bindings from the environment. Changing the value of a variable is still possible unless the binding has been locked. The namespace environments of packages with namespaces are locked when loaded.

`lockBinding` locks individual bindings in the specified environment. The value of a locked binding cannot be changed. Locked bindings may be removed from an environment unless the environment is locked.
makeActiveBinding installs fun in environment env so that getting the value of sym calls fun with no arguments, and assigning to sym calls fun with one argument, the value to be assigned. This allows the implementation of things like C variables linked to R variables and variables linked to databases, and is used to implement setRefClass. It may also be useful for making thread-safe versions of some system globals.

Value

The bindingIsLocked and environmentIsLocked return a length-one logical vector. The remaining functions return NULL, invisibly.

Author(s)

Luke Tierney

Examples

# locking environments
e <- new.env()
assign("x", 1, envir = e)
get("x", envir = e)
lockEnvironment(e)
get("x", envir = e)

f red
Description

Logical operations on integer vectors with elements viewed as sets of bits.

Usage

bitwNot(a)
bitwAnd(a, b)
bitwOr(a, b)
bitwXor(a, b)

bitwShiftL(a, n)
bitwShiftR(a, n)

Arguments

a, b  integer vectors; numeric vectors are coerced to integer vectors.

n  non-negative integer vector of values up to 31.

Details

Each element of an integer vector has 32 bits.
Pairwise operations can result in integer NA.
Shifting is done assuming the values represent unsigned integers.

Value

An integer vector of length the longer of the arguments, or zero length if one is zero-length.
The output element is NA if an input is NA (after coercion) or an invalid shift.

See Also

The logical operators, !, &, |, xor. Notably these do work bitwise for raw arguments.
The classes "octmode" and "hexmode" whose implementation of the standard logical operators is based on these functions.
Package bitops has similar functions for numeric vectors which differ in the way they treat integers $2^{31}$ or larger.

Examples

bitwNot(0:12) # -1 -2 ... -13
bitwAnd(15L, 7L) # 7
bitwOr (15L, 7L) # 15
bitwXor(15L, 7L) # 8
bitwXor(-1L, 1L) # -2

## The "same" for 'raw' instead of integer :

## The "same" for 'raw' instead of integer :
Access to and Manipulation of the Body of a Function

**Description**

Get or set the body of a function.

**Usage**

```r
body(fun = sys.function(sys.parent()))
body(fun, envir = environment(fun)) <- value
```

**Arguments**

- **fun**
  - a function object, or see ‘Details’.
- **envir**
  - environment in which the function should be defined.
- **value**
  - an object, usually a language object: see section ‘Value’.

**Details**

For the first form, `fun` can be a character string naming the function to be manipulated, which is searched for from the parent frame. If it is not specified, the function calling `body` is used.

The bodies of all but the simplest are braced expressions, that is calls to `{`: see the ‘Examples’ section for how to create such a call.

**Value**

`body` returns the body of the function specified. This is normally a language object, most often a call to `{`, but it can also be an object (e.g., `pi`) to be the return value of the function.

The replacement form sets the body of a function to the object on the right hand side, and (potentially) resets the environment of the function. If `value` is of class "expression" the first element is used as the body: any additional elements are ignored, with a warning.

**See Also**

- `alist`, `args`, `function`. 

rr12 <- as.raw(0:12); rbind(rr12, !rr12)
c(r15 <- as.raw(15), r7 <- as.raw(7)) # 0f 07
r15 & r7 # 07
r15 | r7 # 0f
xor(r15, r7)# 08

bitwShiftR(-1, 1:31) # shifts of 2^32-1 = 4294967295
Examples

```r
body(body)
f <- function(x) x^5
body(f) <- quote(5^x)
## or equivalently body(f) <- expression(5^x)
f(3) # = 125
body(f)

## creating a multi-expression body
e <- expression(y <- x^2, return(y)) # or a list
body(f) <- as.call(c(as.name(""), e))
f
f(8)

## Using substitute() may be simpler than 'as.call(c(as.name("",...)))':
stopifnot(identical(body(f), substitute({ y <- x^2; return(y) })))
```

---

**bquote**

*Partial substitution in expressions*

**Description**

An analogue of the LISP backquote macro. `bquote` quotes its argument except that terms wrapped in .() are evaluated in the specified `where` environment.

**Usage**

```r
bquote(expr, where = parent.frame())
```

**Arguments**

- `expr`: A language object.
- `where`: An environment.

**Value**

A language object.

**See Also**

`quote`, `substitute`

**Examples**

```r
require(graphics)
a <- 2
bquote(a == a)
quote(a == a)

bquote(a == .(a))
substitute(a == A, list(A = a))
```
plot(1:10, a*(1:10), main = bquote(a == .(a)))

## to set a function default arg
default <- 1
bquote( function(x, y = .(default)) x+y )

### browser

**Description**

Interrupt the execution of an expression and allow the inspection of the environment where `browser` was called from.

**Usage**

```r
browser(text = "", condition = NULL, expr = TRUE, skipCalls = 0L)
```

**Arguments**

- `text` a text string that can be retrieved once the browser is invoked.
- `condition` a condition that can be retrieved once the browser is invoked.
- `expr` An expression, which if it evaluates to `TRUE` the debugger will invoked, otherwise control is returned directly.
- `skipCalls` how many previous calls to skip when reporting the calling context.

**Details**

A call to `browser` can be included in the body of a function. When reached, this causes a pause in the execution of the current expression and allows access to the R interpreter.

The purpose of the `text` and `condition` arguments are to allow helper programs (e.g., external debuggers) to insert specific values here, so that the specific call to `browser` (perhaps its location in a source file) can be identified and special processing can be achieved. The values can be retrieved by calling `browserText` and `browserCondition`.

The purpose of the `expr` argument is to allow for the illusion of conditional debugging. It is an illusion, because execution is always paused at the call to `browser`, but control is only passed to the evaluator described below if `expr` evaluates to `TRUE`. In most cases it is going to be more efficient to use an `if` statement in the calling program, but in some cases using this argument will be simpler.

The `skipCalls` argument should be used when the `browser()` call is nested within another debugging function: it will look further up the call stack to report its location.

At the browser prompt the user can enter commands or R expressions, followed by a newline. The commands are

- `c` exit the browser and continue execution at the next statement.
- `cont` synonym for c.
- `f` finish execution of the current loop or function
- `help` print this list of commands
n evaluate the next statement, stepping over function calls. For byte compiled functions interrupted
by browser calls, n is equivalent to c.
s evaluate the next statement, stepping into function calls. Again, byte compiled functions make s
equivalent to c.
where print a stack trace of all active function calls.
r invoke a "resume" restart if one is available; interpreted as an R expression otherwise. Typically
"resume" restarts are established for continuing from user interrupts.
Q exit the browser and the current evaluation and return to the top-level prompt.

Leading and trailing whitespace is ignored, except for an empty line. Handling of empty lines
depends on the "browserNLdisabled" option; if it is TRUE, empty lines are ignored. If not, an
empty line is the same as n (or s, if it was used most recently).
Anything else entered at the browser prompt is interpreted as an R expression to be evaluated in
the calling environment: in particular typing an object name will cause the object to be printed, and
ls() lists the objects in the calling frame. (If you want to look at an object with a name such as n,
print it explicitly.)
The number of lines printed for the deparsed call can be limited by setting
options(deparse.max.lines).
The browser prompt is of the form Browse[n]>: here var{n} indicates the ‘browser level’. The
browser can be called when browsing (and often is when debug is in use), and each recursive call
increases the number. (The actual number is the number of ‘contexts’ on the context stack: this is
usually 2 for the outer level of browsing and 1 when examining dumps in debugger.)
This is a primitive function but does argument matching in the standard way.

browserText

Functions to Retrieve Values Supplied by Calls to the Browser

Description

A call to browser can provide context by supplying either a text argument or a condition argument.
These functions can be used to retrieve either of these arguments.

Usage

browserText(n = 1)
browserCondition(n = 1)
browserSetDebug(n = 1)
Arguments

n  The number of contexts to skip over, it must be non-negative.

Details

Each call to browser can supply either a text string or a condition. The functions browserText and browserCondition provide ways to retrieve those values. Since there can be multiple browser contexts active at any time we also support retrieving values from the different contexts. The innermost (most recently initiated) browser context is numbered 1: other contexts are numbered sequentially. browserSetDebug provides a mechanism for initiating the browser in one of the calling functions. See sys.frame for a more complete discussion of the calling stack. To use browserSetDebug you select some calling function, determine how far back it is in the call stack and call browserSetDebug with n set to that value. Then, by typing c at the browser prompt you will cause evaluation to continue, and provided there are no intervening calls to browser or other interrupts, control will halt again once evaluation has returned to the closure specified. This is similar to the up functionality in gdb or the “step out” functionality in other debuggers.

Value

browserText returns the text, while browserCondition returns the condition from the specified browser context.
browserSetDebug returns NULL, invisibly.

Note

It may be of interest to allow for querying further up the set of browser contexts and this functionality may be added at a later date.

browser

builtins  Returns the Names of All Built-in Objects

Description

Return the names of all the built-in objects. These are fetched directly from the symbol table of the R interpreter.

Usage

builtins(internal = FALSE)

Arguments

internal  a logical indicating whether only ‘internal’ functions (which can be called via .Internal) should be returned.
by

Details

`builtins()` returns an unsorted list of the objects in the symbol table, that is all the objects in the base environment. These are the built-in objects plus any that have been added subsequently when the base package was loaded. It is less confusing to use `ls(baseenv(), all = TRUE).

`builtins(TRUE)` returns an unsorted list of the names of internal functions, that is those which can be accessed as `.Internal(foo(args ...))` for `foo` in the list.

Value

A character vector.

by

Apply a Function to a Data Frame Split by Factors

Description

Function `by` is an object-oriented wrapper for `tapply` applied to data frames.

Usage

`by(data, INDICES, FUN, ..., simplify = TRUE)`

Arguments

- `data` an R object, normally a data frame, possibly a matrix.
- `INDICES` a factor or a list of factors, each of length `nrow(data)`.
- `FUN` a function to be applied to (usually data-frame) subsets of data.
- `...` further arguments to `FUN`.
- `simplify` logical: see `tapply`.

Details

A data frame is split by row into data frames subsetted by the values of one or more factors, and function `FUN` is applied to each subset in turn.

For the default method, an object with dimensions (e.g., a matrix) is coerced to a data frame and the data frame method applied. Other objects are also coerced to a data frame, but `FUN` is applied separately to (subsets of) each column of the data frame.

Value

An object of class "by", giving the results for each subset. This is always a list if `simplify` is false, otherwise a list or array (see `tapply`).

See Also

`tapply, simplify2array, ave` also applies a function block-wise.
Examples

```r
require(stats)
by(warpbreaks[, 1:2], warpbreaks[,"tension"], summary)
by(warpbreaks[, 1], warpbreaks[, -1], summary)
by(warpbreaks, warpbreaks[,"tension"],
  function(x) lm(breaks ~ wool, data = x))
```

## now suppose we want to extract the coefficients by group
tmp <- with(warpbreaks,
  by(warpbreaks, tension,
    function(x) lm(breaks ~ wool, data = x)))
sapply(tmp, coef)

---

**c**

### Combine Values into a Vector or List

**Description**

This is a generic function which combines its arguments.

The default method combines its arguments to form a vector. All arguments are coerced to a common type which is the type of the returned value, and all attributes except names are removed.

**Usage**

```r
## S3 Generic function
c(...)
```

```r
## Default S3 method:
c(..., recursive = FALSE, use.names = TRUE)
```

**Arguments**

- `...` objects to be concatenated.
- `recursive` logical. If `recursive = TRUE`, the function recursively descends through lists (and pairlists) combining all their elements into a vector.
- `use.names` logical indicating if `names` should be preserved.

**Details**

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`. Pairlists are treated as lists, whereas non-vector components (such names and calls) are treated as one-element lists which cannot be unlisted even if `recursive = TRUE`.

Note that `factor`s are treated only via their internal `integer` codes; one proposal has been to use

```r
c.factor <- function(..., recursive=TRUE) unlist(list(...), recursive=recursive)
```

if factor concatenation by `c()` should give a `factor`.

c is sometimes used for its side effect of removing attributes except names, for example to turn an array into a vector. `as.vector` is a more intuitive way to do this, but also drops names. Note that methods other than the default are not required to do this (and they will almost certainly preserve a class attribute).

This is a **primitive** function.
Value

NULL or an expression or a vector of an appropriate mode. (With no arguments the value is NULL.)

S4 methods

This function is S4 generic, but with argument list (x, ...).

References

See Also

`unlist` and `as.vector` to produce attribute-free vectors.

Examples

```r
# uses with a single argument to drop attributes
x <- 1:4
names(x) <- letters[1:4]
x
c(x)  # has names
as.vector(x)  # no names
dim(x) <- c(2,2)
x
c(x)
as.vector(x)

# append to a list:
ll <- list(A = 1, c = "C")
# do *not* use
ll0 <- list(A = 1, c = "C")
# but rather
ll0 <- list(A = 1, c = list(D = 1))
ll0 <- list(A = 1, c = list(D = 1), recursive = TRUE)
ll0 <- list(A = 1, c = list(D = 1), recursive = TRUE)
ll0 <- list(A = 1, c = list(D = 1), recursive = TRUE)
```

---

**call**  

*Function Calls*

**Description**

Create or test for objects of mode (or type: `typeof`) "call".
Usage

```r
call(name, ...)  
is.call(x)  
as.call(x)
```

Arguments

- `name`: a non-empty character string naming the function to be called.
- `...`: arguments to be part of the call.
- `x`: an arbitrary R object.

Details

call returns an unevaluated function call, that is, an unevaluated expression which consists of the named function applied to the given arguments (`name` must be a quoted string which gives the name of a function to be called). Note that although the call is unevaluated, the arguments `...` are evaluated.

call is a primitive, so the first argument is taken as `name` and the remaining arguments as arguments for the constructed call: if the first argument is named the `name` must partially match `name`.

is.call is used to determine whether `x` is a call (i.e., of mode "call"). Note that `is.language` is also TRUE for calls (but also for symbols and expressions where `is.call()` is false).

Objects of mode "list" can be coerced to mode "call". The first element of the list becomes the function part of the call, so should be a function or the name of one (as a symbol; a quoted string will not do).

All three are primitive functions.

Warning

call should not be used to attempt to evade restrictions on the use of .Internal and other non-API calls.

References

See Also

do.call for calling a function by name and argument list; Recall for recursive calling of functions; further is.language, expression, function.

Examples

```r
is.call(call) #-> FALSE: Functions are NOT calls

## set up a function call to round with argument 10.5
cl <- call("round", 10.5)
is.call(cl) # TRUE
cl
identical(quote(round(10.5)), # <- less functional, but the same
cl) # TRUE

## such a call can also be evaluated.
```
callCC  

Call With Current Continuation

Description

A downward-only version of Scheme’s call with current continuation.

Usage

callCC(fun)

Arguments

fun  
function of one argument, the exit procedure.

Details

callCC provides a non-local exit mechanism that can be useful for early termination of a computation. callCC calls fun with one argument, an exit function. The exit function takes a single argument, the intended return value. If the body of fun calls the exit function then the call to callCC immediately returns, with the value supplied to the exit function as the value returned by callCC.

Author(s)

Luke Tierney
Examples

# The following all return the value 1
callCC(function(k) 1)
callCC(function(k) k(1))
callCC(function(k) (k(1); 2))
callCC(function(k) repeat k(1))

Description

Functions to pass \texttt{R} objects to compiled C/C++ code that has been loaded into \texttt{R}.

Usage

\texttt{Call(.NAME, ..., PACKAGE)}
\texttt{.External(.NAME, ..., PACKAGE)}

Arguments

\texttt{NAME} a character string giving the name of a C function, or an object of class "NativeSymbolInfo", "RegisteredNativeSymbol" or "NativeSymbol" referring to such a name.

\texttt{...} arguments to be passed to the compiled code. Up to 65 for \texttt{Call}.

\texttt{PACKAGE} if supplied, confine the search for a character string \texttt{NAME} to the DLL given by this argument (plus the conventional extension, \texttt{'.so', '.dll',...}). This argument follows \texttt{...} and so its name cannot be abbreviated.

This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols, and also speeds up the search (see ‘Note’).

Details

The functions are used to call compiled code which makes use of internal \texttt{R} objects, passing the arguments to the code as a sequence of \texttt{R} objects. They assume C calling conventions, so can usually also be used of C++ code.

For details about how to write code to use with these functions see the chapter on ‘System and foreign language interfaces’ in the ‘Writing \texttt{R} Extensions’ manual. They differ in the way the arguments are passed to the C code: \texttt{.External} allows for a variable number of arguments.

These functions are \texttt{primitive}, and \texttt{.NAME} is always matched to the first argument supplied (which should not be named). For clarity, avoid using names in the arguments passed to \texttt{...} that match or partially match \texttt{.NAME}.

Value

An \texttt{R} object constructed in the compiled code.
Header files for external code

Writing code for use with these functions will need to use internal \texttt{R} structures defined in \texttt{'Rinternals.h'} and/or the macros in \texttt{'Rdefines.h'}.

Note

If one of these functions is to be used frequently, do specify \texttt{PACKAGE} (to confine the search to a single DLL) or pass \texttt{.NAME} as one of the native symbol objects. Searching for symbols can take a long time, especially when many namespaces are loaded.

You may see \texttt{PACKAGE = "base"} for symbols linked into \texttt{R}. Do not use this in your own code: such symbols are not part of the API and may be changed without warning.

\texttt{PACKAGE = ""} used to be accepted (but was undocumented): it is now an error.

The ‘Writing R Extensions’ manual.

---

**capabilities**

Report Capabilities of this Build of \texttt{R}

Description

Report on the optional features which have been compiled into this build of \texttt{R}.

Usage

capabilities(what = NULL)

Arguments

what character vector or \texttt{NULL}, specifying required components. \texttt{NULL} implies that all are required.

Value

A named logical vector. Current components are

\begin{itemize}
  \item \texttt{jpeg} is the \texttt{jpeg} function operational?
  \item \texttt{png} is the \texttt{png} function operational?
  \item \texttt{tiff} is the \texttt{tiff} function operational?
  \item \texttt{tcltk} is the \texttt{tcltk} package operational? Note that to make use of Tk you will almost always need to check that "X11" is also available.
  \item \texttt{X11} are the \texttt{X11} graphics device and the \texttt{X11}-based data editor available? This loads the \texttt{X11} module if not already loaded, and checks that the default display can be contacted unless a \texttt{X11} device has already been used.
\end{itemize}
### Capabilities

- **aqua**: Is the `quartz` function operational? Only on some macOS builds, including CRAN binary distributions of R. Note that this is distinct from `.Platform$GUI == "AQUA"`, which is true only when using the Mac R.app GUI console.

- **http/ftp**: Does the internal method for `url` and `download.file` support `http://` and `ftp://` URLs? Always TRUE as from R 3.3.0.

- **sockets**: Are `make.socket` and related functions available? Always TRUE as from R 3.3.0.

- **libxml**: Is there support for integrating `libxml` with the R event loop? Always TRUE as from R 3.3.0.

- **fifo**: Are FIFO connections supported?

- **cledit**: Is command-line editing available in the current R session? This is false in non-interactive sessions. It will be true for the command-line interface if readline support has been compiled in and `--no-readline` was not used when R was invoked. (If `--interactive` was used, command-line editing will not actually be available.)

- **iconv**: Is internationalization conversion via `iconv` supported? Always true in current R.

- **NLS**: Is there Natural Language Support (for message translations)?

- **profmem**: Is there support for memory profiling? See `tracemem`.

- **cairo**: Is there support for the `svg`, `cairo_pdf` and `cairo_ps` devices, and for `type = "cairo"` in the `X11`, `bmp`, `jpeg`, `png`, and `tiff` devices?

- **ICU**: Is ICU available for collation? See the help on `Comparison` and `icuSetCollate`: it is never used for a C locale.

- **long.double**: Does this build use a C `long double` type which is longer than `double`? Some platforms do not have such a type, and on others its use can be suppressed by the configure option `--disable-long-double`.

  Although not guaranteed, it is a reasonable assumption that if present long doubles will have at least as much range and accuracy as the ISO/IEC 60559 80-bit 'extended precision' format.

- **libcurl**: Is `libcurl` available in this build? Used by function `curlGetHeaders` and optionally by `download.file` and `url`. As from R 3.3.0 always true for Unix-alikes, and true for CRAN Windows builds.

### Note to macOS users

Capabilities "jpeg", "png" and "tiff" refer to the X11-based versions of these devices. If capabilities("aqua") is true, then these devices with type = "quartz" will be available, and out-of-the-box will be the default type. Thus for example the tiff device will be available if capabilities("aqua") || capabilities("tiff") if the defaults are unchanged.

### See Also

`.Platform` and `extSoftVersion` (and links there) for availability capabilities `external` to R but used from R functions.
Examples

```r
capabilities()
if(!capabilities("ICU"))
  warning("ICU is not available")
```

### See also the examples for 'connections'.

---

**cat**

**Concatenate and Print**

Description

Outputs the objects, concatenating the representations. **cat** performs much less conversion than **print**.

Usage

```r
cat(... , file = "", sep = " ", fill = FALSE, labels = NULL,
    append = FALSE)
```

Arguments

- `...` R objects (see ‘Details’ for the types of objects allowed).
- `file` A connection, or a character string naming the file to print to. If "" (the default), cat prints to the standard output connection, the console unless redirected by `sink`. If it is |cmd|, the output is piped to the command given by `cmd`, by opening a pipe connection.
- `sep` a character vector of strings to append after each element.
- `fill` a logical or (positive) numeric controlling how the output is broken into successive lines. If FALSE (default), only newlines created explicitly by "\n" are printed. Otherwise, the output is broken into lines with print width equal to the option `width` if `fill` is TRUE, or the value of `fill` if this is numeric. Non-positive `fill` values are ignored, with a warning.
- `labels` character vector of labels for the lines printed. Ignored if `fill` is FALSE.
- `append` logical. Only used if the argument `file` is the name of file (and not a connection or "|cmd|”). If TRUE output will be appended to file; otherwise, it will overwrite the contents of file.

Details

**cat** is useful for producing output in user-defined functions. It converts its arguments to character vectors, concatenates them to a single character vector, appends the given sep = string(s) to each element and then outputs them.

No linefeeds are output unless explicitly requested by "\n" or if generated by filling (if argument fill is TRUE or numeric).

If file is a connection and open for writing it is written from its current position. If it is not open, it is opened for the duration of the call in "wt" mode and then closed again.
Currently only atomic vectors and names are handled, together with NULL and other zero-length objects (which produce no output). Character strings are output 'as is' (unlike print.default which escapes non-printable characters and backslash — use encodeString if you want to output encoded strings using cat). Other types of R object should be converted (e.g., by as.character or format) before being passed to cat. That includes factors, which are output as integer vectors. cat converts numeric/complex elements in the same way as print (and not in the same way as as.character which is used by the S equivalent), so options "digits" and "scipen" are relevant. However, it uses the minimum field width necessary for each element, rather than the same field width for all elements.

Value

None (invisible NULL).

Note

If any element of sep contains a newline character, it is treated as a vector of terminators rather than separators, an element being output after every vector element and a newline after the last. Entries are recycled as needed.

References

See Also

print, format, and paste which concatenates into a string.

Examples

```r
iter <- stats::rpois(1, lambda = 10)
## print an informative message
cat("iteration = ", iter <- iter + 1, "\n")

## 'fill' and label lines:
cat(paste(letters, 100* 1:26), fill = TRUE, labels = paste0("{", 1:10, "}:"))
```

---

## cbind

**Combine R Objects by Rows or Columns**

**Description**

Take a sequence of vector, matrix or data-frame arguments and combine by columns or rows, respectively. These are generic functions with methods for other R classes.

**Usage**

```r
cbind(..., deparse.level = 1)
rbind(..., deparse.level = 1)
## S3 method for class 'data.frame'
rbind(..., deparse.level = 1, make.row.names = TRUE,
        stringsAsFactors = default.stringsAsFactors())
```
cbind

Arguments

... (generalized) vectors or matrices. These can be given as named arguments. Other R objects may be coerced as appropriate, or S4 methods may be used: see sections ‘Details’ and ‘Value’. (For the “data.frame” method of cbind these can be further arguments to data.frame such as stringsAsFactors.)

deparse.level integer controlling the construction of labels in the case of non-matrix-like arguments (for the default method):
deparse.level = 0 constructs no labels; the default,
deparse.level = 1 or 2 constructs labels from the argument names, see the ‘Value’ section below.

make.row.names (only for data frame method:) logical indicating if unique and valid row.names should be constructed from the arguments.

stringsAsFactors logical, passed to as.data.frame; only has an effect when the ... arguments contain a (non-data.frame) character.

Details

The functions cbind and rbind are S3 generic, with methods for data frames. The data frame method will be used if at least one argument is a data frame and the rest are vectors or matrices. There can be other methods; in particular, there is one for time series objects. See the section on ‘Dispatch’ for how the method to be used is selected. If some of the arguments are of an S4 class, i.e., isS4(.), is true, S4 methods are sought also, and the hidden cbind / rbind functions from package methods maybe called, which in turn build on cbind2 or rbind2, respectively. In that case, deparse.level is obeyed, similarly to the default method.

In the default method, all the vectors/matrices must be atomic (see vector) or lists. Expressions are not allowed. Language objects (such as formulae and calls) and pairlists will be coerced to lists: other objects (such as names and external pointers) will be included as elements in a list result. Any classes the inputs might have are discarded (in particular, factors are replaced by their internal codes).

If there are several matrix arguments, they must all have the same number of columns (or rows) and this will be the number of columns (or rows) of the result. If all the arguments are vectors, the number of columns (rows) in the result is equal to the length of the longest vector. Values in shorter arguments are recycled to achieve this length (with a warning if they are recycled only fractionally).

When the arguments consist of a mix of matrices and vectors the number of columns (rows) of the result is determined by the number of columns (rows) of the matrix arguments. Any vectors have their values recycled or subsetted to achieve this length.

For cbind (rbind), vectors of zero length (including NULL) are ignored unless the result would have zero rows (columns), for S compatibility. (Zero-extent matrices do not occur in S3 and are not ignored in R.)

Matrices are restricted to less than $2^{31}$ rows and columns even on 64-bit systems. So input vectors have the same length restriction: as from R 3.2.0 input matrices with more elements (but meeting the row and column restrictions) are allowed.

Value

For the default method, a matrix combining the ... arguments column-wise or row-wise. (Exception: if there are no inputs or all the inputs are NULL, the value is NULL.)

The type of a matrix result determined from the highest type of any of the inputs in the hierarchy raw < logical < integer < double < complex < character < list .
For \texttt{cbind} (\texttt{rbind}) the column (row) names are taken from the \texttt{colnames} (\texttt{rownames}) of the arguments if these are matrix-like. Otherwise from the names of the arguments or where those are not supplied and \texttt{deparse.level} \textgreater{} 0, by deparsing the expressions given, for \texttt{deparse.level} = 1 only if that gives a sensible name (a ‘symbol’, see \texttt{is.symbol}).

For \texttt{cbind} row names are taken from the first argument with appropriate names: \texttt{rownames} for a matrix, or names for a vector of length the number of rows of the result.

For \texttt{rbind} column names are taken from the first argument with appropriate names: \texttt{colnames} for a matrix, or names for a vector of length the number of columns of the result.

**Data frame methods**

The \texttt{cbind} data frame method is just a wrapper for \texttt{data.frame(..., check.names = FALSE)}. This means that it will split matrix columns in data frame arguments, and convert character columns to factors unless \texttt{stringsAsFactors = FALSE} is specified.

The \texttt{rbind} data frame method first drops all zero-column and zero-row arguments. (If that leaves none, it returns the first argument with columns otherwise a zero-column zero-row data frame.) It then takes the classes of the columns from the first data frame, and matches columns by name (rather than by position). Factors have their levels expanded as necessary (in the order of the levels of the levelsets of the factors encountered) and the result is an ordered factor if and only if all the components were ordered factors. (The last point differs from S-PLUS.) Old-style categories (integer vectors with levels) are promoted to factors.

**Dispatch**

The method dispatching is not done via \texttt{UseMethod()}, but by C-internal dispatching. Therefore there is no need for, e.g., \texttt{rbind.default}.

The dispatch algorithm is described in the source file (‘.../src/main/bind.c’) as

1. For each argument we get the list of possible class memberships from the class attribute.
2. We inspect each class in turn to see if there is an applicable method.
3. If we find an applicable method we make sure that it is identical to any method determined for prior arguments. If it is identical, we proceed, otherwise we immediately drop through to the default code.

If you want to combine other objects with data frames, it may be necessary to coerce them to data frames first. (Note that this algorithm can result in calling the data frame method if all the arguments are either data frames or vectors, and this will result in the coercion of character vectors to factors.)

**References**

**See Also**

\texttt{c} to combine vectors (and lists) as vectors, \texttt{data.frame} to combine vectors and matrices as a data frame.
Examples

```r
m <- cbind(1, 1:7) # the '1' (= shorter vector) is recycled
m
m <- cbind(m, 8:14)[, c(1, 3, 2)] # insert a column
m
cbind(1:7, diag(3)) # vector is subset -> warning

cbind(0, rbind(1, 1:3))
cbind(I = 0, X = rbind(a = 1, b = 1:3)) # use some names
xx <- data.frame(I = rep(0, 2))
cbind(xx, X = rbind(a = 1, b = 1:3)) # named differently

cbind(0, matrix(1, nrow = 0, ncol = 4)) #> Warning (making sense)
dim(cbind(0, matrix(1, nrow = 2, ncol = 0))) #=> 2 x 1

## deparse.level
dd <- 10
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 0) # middle 2 rownames
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 1) # 3 rownames (default)
rbind(1:4, c = 2, "a++" = 10, dd, deparse.level = 2) # 4 rownames

## cheap row names:
b0 <- gl(3,4, labels=letters[1:3])
bf <- setNames(b0, paste0("o", seq_along(b0)))
df <- data.frame(a = 1, B = b0, f = gl(4,3))
df. <- data.frame(a = 1, B = bf, f = gl(4,3))
new <- data.frame(a = 8, B = "B", f = "1")
(df1 <- rbind(df , new))
(df.1 <- rbind(df., new))
stopifnot(identical(df1, rbind(df, new, make.row.names=FALSE)),
          identical(df1, rbind(df., new, make.row.names=FALSE)))
```

char.expand

Expand a String with Respect to a Target Table

Description

Seeks a unique match of its first argument among the elements of its second. If successful, it returns this element; otherwise, it performs an action specified by the third argument.

Usage

```r
char.expand(input, target, nomatch = stop("no match"))
```

Arguments

- `input` a character string to be expanded.
- `target` a character vector with the values to be matched against.
- `nomatch` an R expression to be evaluated in case expansion was not possible.
Details

This function is particularly useful when abbreviations are allowed in function arguments, and need to be uniquely expanded with respect to a target table of possible values.

Value

A length-one character vector, one of the elements of target (unless nomatch is changed to be a non-error, when it can be a zero-length character string).

See Also

charmatch and pmatch for performing partial string matching.

Examples

locPars <- c("mean", "median", "mode")
char.expand("me", locPars, warning("Could not expand!"))
char.expand("mo", locPars)

character

Character Vectors

Description

Create or test for objects of type "character".

Usage

character(length = 0)
as.character(x, ...)
is.character(x)

Arguments

length A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
x object to be coerced or tested.
... further arguments passed to or from other methods.

Details

as.character and is.character are generic: you can write methods to handle specific classes of objects, see InternalMethods. Further, for as.character the default method calls as.vector, so dispatch is first on methods for as.character and then for methods for as.vector.
as.character represents real and complex numbers to 15 significant digits (technically the compiler's setting of the ISO C constant DBL_DIG, which will be 15 on machines supporting IEC60559 arithmetic according to the C99 standard). This ensures that all the digits in the result will be reliable (and not the result of representation error), but does mean that conversion to character and back to numeric may change the number. If you want to convert numbers to character with the maximum possible precision, use format.
Value

character creates a character vector of the specified length. The elements of the vector are all equal to "".

as.character attempts to coerce its argument to character type; like as.vector it strips attributes including names. For lists and pairlists (including language objects such as calls) it deparses the elements individually, except that it extracts the first element of length-one character vectors.

is.character returns TRUE or FALSE depending on whether its argument is of character type or not.

Note

as.character breaks lines in language objects at 500 characters, and inserts newlines. Prior to 2.15.0 lines were truncated.

References

See Also

options: option scipen affects the conversion of numbers.
paste, substr and strsplit for character concatenation and splitting, chartr for character translation and casefolding (e.g., upper to lower case) and sub, grep etc for string matching and substitutions. Note that help.search(keyword = "character") gives even more links.
deparse, which is normally preferable to as.character for language objects.

Examples

form <- y ~ a + b + c
as.character(form) ## length 3
deparse(form) ## like the input

a0 <- 11/999 # has a repeating decimal representation
(a1 <- as.character(a0))
format(a0, digits = 16) # shows one more digit
a2 <- as.numeric(a1)
a2 - a0 # normally around -1e-17
as.character(a2) # normally different from a1
print(c(a0, a2), digits = 16)

---

charmatch **Partial String Matching**

Description

charmatch seeks matches for the elements of its first argument among those of its second.

Usage

charmatch(x, table, nomatch = NA_integer_)
Arguments

x the values to be matched: converted to a character vector by as.character. Long vectors are supported.

table the values to be matched against: converted to a character vector. Long vectors are not supported.

nomatch the (integer) value to be returned at non-matching positions.

Details

Exact matches are preferred to partial matches (those where the value to be matched has an exact match to the initial part of the target, but the target is longer).

If there is a single exact match or no exact match and a unique partial match then the index of the matching value is returned; if multiple exact or multiple partial matches are found then 0 is returned and if no match is found then nomatch is returned.

NA values are treated as the string constant "NA".

Value

An integer vector of the same length as x, giving the indices of the elements in table which matched, or nomatch.

Author(s)

This function is based on a C function written by Terry Therneau.

See Also

pmatch, match.

startsWith for another matching of initial parts of strings; grep or regexpr for more general (regexp) matching of strings.

Examples

charmatch("", ") # returns 1
charmatch("m", c("mean", "median", "mode")) # returns 0
charmatch("med", c("mean", "median", "mode")) # returns 2

chartr Character Translation and Casefolding

Description

Translate characters in character vectors, in particular from upper to lower case or vice versa.

Usage

chartr(old, new, x)
tolower(x)
toupper(x)
casefold(x, upper = FALSE)
Arguments

- **x**: a character vector, or an object that can be coerced to character by `as.character`.
- **old**: a character string specifying the characters to be translated. If a character vector of length 2 or more is supplied, the first element is used with a warning.
- **new**: a character string specifying the translations. If a character vector of length 2 or more is supplied, the first element is used with a warning.
- **upper**: logical: translate to upper or lower case?

Details

`chartr` translates each character in `x` that is specified in `old` to the corresponding character specified in `new`. Ranges are supported in the specifications, but character classes and repeated characters are not. If `old` contains more characters than `new`, an error is signaled; if it contains fewer characters, the extra characters at the end of `new` are ignored.

tolower and toupper convert upper-case characters in a character vector to lower-case, or vice versa. Non-alphabetic characters are left unchanged.

casefold is a wrapper for tolower and toupper provided for compatibility with S-PLUS.

Value

A character vector of the same length and with the same attributes as `x` (after possible coercion).

Elements of the result will be having the encoding declared as that of the current locale (see `Encoding` if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8. The result will be in the current locale’s encoding unless the corresponding input was in UTF-8, when it will be in UTF-8 when the system has Unicode wide characters.

See Also

- `sub` and `gsub` for other substitutions in strings.

Examples

```r
x <- "MiXeD cAsE 123"
chartr("iXs", "why", x)
chartr("a-cX", "D-Fw", x)
tolower(x)
toupper(x)
```

```r
### "Mixed Case" Capitalizing - toupper( every first letter of a word ) :

.simpleCap <- function(x) {
  s <- strsplit(x, " ")[[1]]
  paste(toupper(substring(s, 1, 1)), substring(s, 2),
       sep = "", collapse = " ")
}
.simpleCap("the quick red fox jumps over the lazy brown dog")
```

```r
### and the better, more sophisticated version:
capwords <- function(s, strict = FALSE) {
  cap <- function(s) paste(toupper(substring(s, 1, 1))),
  (s <- substring(s, 2); if(strict) tolower(s) else s),
```
chkDots

Warn About Extraneous Arguments in the "..." of Its Caller

Description

Warn about extraneous arguments in the ... of its caller. A utility to be used e.g., in S3 methods which need a formal ... argument but do not make any use of it. This helps catching user errors in calling the function in question (which is the caller of chkDots()).

Usage

chkDots(..., which.call = -1, allowed = character(0))

Arguments

...                   "the dots", as passed from the caller.
which.call            passed to sys.call(). A caller may use -2 if the message should mention its caller.
allowed               not yet implemented: character vector of named elements in ... which are "allowed" and hence not warned about.

Author(s)

Martin Maechler, first version outside base, June 2012.

warning, ....
The Choleski Decomposition

Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

Usage

chol(x, ...)

## Default S3 method:
chol(x, pivot = FALSE, LINPACK = FALSE, tol = -1, ...)

Arguments

x
an object for which a method exists. The default method applies to numeric (or logical) symmetric, positive-definite matrices.

...arguments to be based to or from methods.

pivotShould pivoting be used?

LINPACKlogical. Should LINPACK be used (now ignored)?

tolA numeric tolerance for use with pivot = TRUE.

Details

chol is generic: the description here applies to the default method.

Note that only the upper triangular part of x is used, so that \( R' R = x \) when x is symmetric.

If pivot = FALSE and x is not non-negative definite an error occurs. If x is positive semi-definite (i.e., some zero eigenvalues) an error will also occur as a numerical tolerance is used.

If pivot = TRUE, then the Choleski decomposition of a positive semi-definite x can be computed. The rank of x is returned as attr(Q, "rank"), subject to numerical errors. The pivot is returned as attr(Q, "pivot"). It is no longer the case that t(Q) \%*% Q equals x. However, setting pivot <- attr(Q, "pivot") and oo <- order(pivot), it is true that t(Q[, oo]) \%*% Q[, oo] equals x, or, alternatively, t(Q) \%*% Q equals x[pivot, pivott]. See the examples.

The value of tol is passed to LAPACK, with negative values selecting the default tolerance of (usually) \( \text{nr}(x) \times \text{.Machine}$double.neg.eps \times \text{max(diag(x))} \). The algorithm terminates once the pivot is less than tol.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.
chol

Value

The upper triangular factor of the Choleski decomposition, i.e., the matrix \( R \) such that \( R'R = x \) (see example).

If pivoting is used, then two additional attributes "pivot" and "rank" are also returned.

Warning

The code does not check for symmetry.

If \( \text{pivot} = \text{TRUE} \) and \( x \) is not non-negative definite then there will be a warning message but a meaningless result will occur. So only use \( \text{pivot} = \text{TRUE} \) when \( x \) is non-negative definite by construction.

\text{crossprod(Q[, order(pivot)])} & \quad \text{# recover m}
\end{align*}
\]
## now for a non-positive-definite matrix

```r
( m <- matrix(c(5,-5,-5,3), 2, 2) )
try(chol(m)) # fails
(Q <- chol(m, pivot = TRUE)) # warning
crossprod(Q) # not equal to m
```

### chol2inv

**Inverse from Choleski (or QR) Decomposition**

**Description**

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute $(X'X)^{-1}$ from the $(R$ part$)$ of the QR decomposition of $X$.

**Usage**

```r
chol2inv(x, size = NCOL(x), LINPACK = FALSE)
```

**Arguments**

- `x`: a matrix. The first `size` columns of the upper triangle contain the Choleski decomposition of the matrix to be inverted.
- `size`: the number of columns of `x` containing the Choleski decomposition.
- `LINPACK`: logical. Defunct and ignored (with a warning for true value).

**Value**

The inverse of the matrix whose Choleski decomposition was given.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

**Source**

This is an interface to the LAPACK routine `DPOTRI`. LAPACK is from [http://www.netlib.org/lapack](http://www.netlib.org/lapack) and its guide is listed in the references.

**References**

**See Also**

`chol`, `solve`.

**Examples**

```r
cma <- chol(ma <- cbind(1, 1:3, c(1,3,7)))
ma %*% chol2inv(cma)
```
class Object Classes

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class of the first argument to the generic function.

Usage

class(x)
class(x) <- value
unclass(x)
inherits(x, what, which = FALSE)

oldClass(x)
oldClass(x) <- value

Arguments

x a R object
what, value a character vector naming classes. value can also be NULL.
which logical affecting return value: see ‘Details’.

Details

Here, we describe the so called “S3” classes (and methods). For “S4” classes (and methods), see ‘Formal classes’ below.

Many R objects have a class attribute, a character vector giving the names of the classes from which the object inherits. (Functions oldClass and oldClass<- get and set the attribute, which can also be done directly.)

If the object does not have a class attribute, it has an implicit class, notably “matrix”, “array”, “function” or “numeric” or the result of typeof(x) (which is similar to mode(x)), but for type “language” and mode “call”, where the following extra classes exist for the corresponding function calls: if, while, for, =, <-, , , call.

Note that NULL objects cannot have attributes (hence not classes) and attempting to assign a class is an error.

When a generic function fun is applied to an object with class attribute c("first", "second"), the system searches for a function called fun.first and, if it finds it, applies it to the object. If no such function is found, a function called fun.second is tried. If no class name produces a suitable function, the function fun.default is used (if it exists). If there is no class attribute, the implicit class is tried, then the default method.

The function class prints the vector of names of classes an object inherits from. Correspondingly, class<- sets the classes an object inherits from. Assigning NULL removes the class attribute.

unclass returns (a copy of) its argument with its class attribute removed. (It is not allowed for objects which cannot be copied, namely environments and external pointers.)

inherits indicates whether its first argument inherits from any of the classes specified in the what argument. If which is TRUE then an integer vector of the same length as what is returned. Each
element indicates the position in the \texttt{class(x)} matched by the element of \texttt{what}; zero indicates no match. If which is FALSE then TRUE is returned by \texttt{inherits} if any of the names in \texttt{what} match with any class.

All but \texttt{inherits} are \texttt{primitive} functions.

\textbf{Formal classes}

An additional mechanism of \textit{formal classes}, nicknamed “S4”, is available in package \texttt{methods} which is attached by default. For objects which have a formal class, its name is returned by \texttt{class} as a character vector of length one and method dispatch can happen on \textit{several} arguments, instead of only the first. However, S3 method selection attempts to treat objects from an S4 class as if they had the appropriate S3 class attribute, as does \texttt{inherits}. Therefore, S3 methods can be defined for S4 classes. See the ‘\texttt{Introduction}’ and ‘\texttt{Methods_for_S3}’ help pages for basic information on S4 methods and for the relation between these and S3 methods.

The replacement version of the function sets the class to the value provided. For classes that have a formal definition, directly replacing the class this way is strongly deprecated. The expression \texttt{as(object, value)} is the way to coerce an object to a particular class.

The analogue of \texttt{inherits} for formal classes is \texttt{is}. The two functions behave consistently with one exception: S4 classes can have conditional inheritance, with an explicit test. In this case, \texttt{is} will test the condition, but \texttt{inherits} ignores all conditional superclasses.

\textbf{Note}

Functions \texttt{oldClass} and \texttt{oldClass<-} behave in the same way as functions of those names in S-PLUS 5/6, but in R \texttt{UseMethod} dispatches on the class as returned by \texttt{class} (with some interpolated classes: see the link) rather than \texttt{oldClass}. \textit{However}, \texttt{group generic}s dispatch on the \texttt{oldClass} for efficiency, and \texttt{internal generic}s only dispatch on objects for which \texttt{is.object} is true.

In older versions of R, assigning a zero-length vector with \texttt{class} removed the class: it is now an error (whereas it still works for \texttt{oldClass}). It is clearer to always assign \texttt{NULL} to remove the class.

\textbf{See Also}

\texttt{UseMethod}, \texttt{NextMethod}, ‘\texttt{group generic}’, ‘\texttt{internal generic}’

\textbf{Examples}

\begin{verbatim}
 x <- 10
 class(x) # "numeric"
 oldClass(x) # NULL
 inherits(x, "a") #FALSE
 class(x) <- c("a", "b")
 inherits(x,"a") #TRUE
 inherits(x, "a", TRUE) # 1
 inherits(x, c("a", "b", "c"), TRUE) # 1 2 0

class( quote(pi) ) # "name"
## regular calls
 class( quote(sin(pi*x)) ) # "class"
## special calls
 class( quote(x <- 1) ) # "<-"
 class( quote((1 < 2)) ) # "]"
 class( quote( if(8<3) pi ) ) # "if"
\end{verbatim}
Description

Returns a matrix of integers indicating their column number in a matrix-like object, or a factor of column labels.

Usage

\texttt{col(x, \text{as.factor} = \text{FALSE})}
\texttt{.col(dim)}

Arguments

\begin{itemize}
\item \textit{x} \quad \text{a matrix-like object, that is one with a two-dimensional \texttt{dim}.}
\item \textit{dim} \quad \text{a matrix dimension, i.e., \texttt{integer} vector of length two (with non-negative entries).}
\item \textit{as.factor} \quad \text{a logical value indicating whether the value should be returned as a factor of column labels (created if necessary) rather than as numbers.}
\end{itemize}

Value

An integer (or factor) matrix with the same dimensions as \textit{x} and whose i\text{j}-th element is equal to \textit{j} (or the \text{j}-th column label).

References

See Also

\texttt{row} to get rows.

Examples

\begin{verbatim}
# extract an off-diagonal of a matrix
ma <- matrix(1:12, 3, 4)
ma[row(ma) == col(ma) + 1]

# create an identity 5-by-5 matrix more slowly than \texttt{diag(n = 5)}:
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1
\end{verbatim}
Colon

Colon Operator

Description

Generate regular sequences.

Usage

from:to
  a:b

Arguments

from     starting value of sequence.
to       (maximal) end value of the sequence.
a, b     factors of the same length.

Details

The binary operator : has two meanings: for factors a:b is equivalent to interaction(a, b) (but the levels are ordered and labelled differently).

For other arguments from:to is equivalent to seq(from, to), and generates a sequence from from to to in steps of 1 or -1. Value to will be included if it differs from from by an integer up to a numeric fuzz of about 1e-7. Non-numeric arguments are coerced internally (hence without dispatching methods) to numeric—complex values will have their imaginary parts discarded with a warning.

Value

For numeric arguments, a numeric vector. This will be of type integer if from is integer-valued and the result is representable in the R integer type, otherwise of type "double" (aka mode "numeric").

For factors, an unordered factor with levels labelled as 1a:1b and ordered lexicographically (that is, 1b varies fastest).

References

(for numeric arguments: S does not have : for factors.)

See Also

seq (a generalization of from:to).

As an alternative to using : for factors, interaction.

For : used in the formal representation of an interaction, see formula.
Examples

1:4
pi:6 # real
6:pi # integer

f1 <- gl(2, 3); f1
f2 <- gl(3, 2); f2
f1:f2 # a factor, the "cross" f1 x f2

colSums

Form Row and Column Sums and Means

Description

Form row and column sums and means for numeric arrays (or data frames).

Usage

colSums (x, na.rm = FALSE, dims = 1)
rowSums (x, na.rm = FALSE, dims = 1)
colMeans(x, na.rm = FALSE, dims = 1)
rowMeans(x, na.rm = FALSE, dims = 1)

.colSums(x, m, n, na.rm = FALSE)
.rowSums(x, m, n, na.rm = FALSE)
.colMeans(x, m, n, na.rm = FALSE)
.rowMeans(x, m, n, na.rm = FALSE)

Arguments

x an array of two or more dimensions, containing numeric, complex, integer or logical values, or a numeric data frame. For .colSums() etc, a numeric, integer or logical matrix (or vector of length m * n).
na.rm logical. Should missing values (including NaN) be omitted from the calculations?
dims integer: Which dimensions are regarded as 'rows' or 'columns' to sum over. For row*, the sum or mean is over dimensions dims+1, ...; for col* it is over dimensions 1:dims.
m, n the dimensions of the matrix x for .colSums() etc.

Details

These functions are equivalent to use of apply with FUN = mean or FUN = sum with appropriate margins, but are a lot faster. As they are written for speed, they blur over some of the subtleties of NaN and NA. If na.rm = FALSE and either NaN or NA appears in a sum, the result will be one of NaN or NA, but which might be platform-dependent.

Notice that omission of missing values is done on a per-column or per-row basis, so column means may not be over the same set of rows, and vice versa. To use only complete rows or columns, first select them with na.omit or complete.cases (possibly on the transpose of x).

The versions with an initial dot in the name (.colSums() etc) are ‘bare-bones’ versions for use in programming: they apply only to numeric (like) matrices and do not name the result.
commandArgs

Value

A numeric or complex array of suitable size, or a vector if the result is one-dimensional. For the first four functions the dimnames (or names for a vector result) are taken from the original array.

If there are no values in a range to be summed over (after removing missing values with na.rm = TRUE), that component of the output is set to 0 (Sums) or NaN (Means), consistent with sum and mean.

See Also

apply, rowsum

Examples

### Compute row and column sums for a matrix:

```r
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
rowSums(x); colSums(x)
dimnames(x)[[1]] <- letters[1:8]
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
x[] <- as.integer(x)
rowSums(x); colSums(x)
x[] <- x < 3
rowSums(x); colSums(x)
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)
```

### an array

```r
dim(UCBAdmissions)
rowSums(UCBAdmissions); rowSums(UCBAdmissions, dims = 2)
colSums(UCBAdmissions); colSums(UCBAdmissions, dims = 2)
```

### complex case

```r
x <- cbind(x1 = 3 + 2i, x2 = c(4:1, 2:5) - 5i)
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)
```

---

commandArgs

**Extract Command Line Arguments**

Description

Provides access to a copy of the command line arguments supplied when this R session was invoked.

Usage

```r
commandArgs(trailingOnly = FALSE)
```

Arguments

- **trailingOnly**
  
  logical. Should only arguments after '--args' be returned?
Details

These arguments are captured before the standard R command line processing takes place. This means that they are the unmodified values. This is especially useful with the ‘--args’ command-line flag to R, as all of the command line after that flag is skipped.

Value

A character vector containing the name of the executable and the user-supplied command line arguments. The first element is the name of the executable by which R was invoked. The exact form of this element is platform dependent: it may be the fully qualified name, or simply the last component (or basename) of the application, or for an embedded R it can be anything the programmer supplied. If trailingOnly = TRUE, a character vector of those arguments (if any) supplied after ‘--args’.

See Also

Startup BATCH

Examples

commandArgs()

## Spawn a copy of this application as it was invoked,
## subject to shell quoting issues
## system(paste(commandArgs(), collapse = " "))

comment

Query or Set a "comment" Attribute

Description

These functions set and query a comment attribute for any R objects. This is typically useful for data.frames or model fits.

Contrary to other attributes, the comment is not printed (by print or print.default).

Assigning NULL or a zero-length character vector removes the comment.

Usage

comment(x)

comment(x) <- value

Arguments

x any R object

value a character vector, or NULL.

See Also

attributes and attr for other attributes.
Examples

```r
x <- matrix(1:12, 3, 4)
comment(x) <- c("This is my very important data from experiment #0234",
               "Jun 5, 1998")
x
comment(x)
```

### Description

Binary operators which allow the comparison of values in atomic vectors.

#### Usage

```r
x < y
x > y
x <= y
x >= y
x == y
x != y
```

#### Arguments

- `x, y`: atomic vectors, symbols, calls, or other objects for which methods have been written.

#### Details

The binary comparison operators are generic functions: methods can be written for them individually or via the `Ops` group generic function. (See `Ops` for how dispatch is computed.)

Comparison of strings in character vectors is lexicographic within the strings using the collating sequence of the locale in use: see `locales`. The collating sequence of locales such as `en_US` is normally different from `C` (which should use ASCII) and can be surprising. Beware of making any assumptions about the collation order: e.g. in Estonian Z comes between S and T, and collation is not necessarily character-by-character – in Danish aa sorts as a single letter, after z. In Welsh ng may or may not be a single sorting unit: if it is it follows g. Some platforms may not respect the locale and always sort in numerical order of the bytes in an 8-bit locale, or in Unicode code-point order for a UTF-8 locale (and may not sort in the same order for the same language in different character sets). Collation of non-letters (spaces, punctuation signs, hyphens, fractions and so on) is even more problematic.

Character strings can be compared with different marked encodings (see `Encoding`): they are translated to UTF-8 before comparison.

Raw vectors should not really be considered to have an order, but the numeric order of the byte representation is used.

At least one of `x` and `y` must be an atomic vector, but if the other is a list R attempts to coerce it to the type of the atomic vector: this will succeed if the list is made up of elements of length one that can be coerced to the correct type.
If the two arguments are atomic vectors of different types, one is coerced to the type of the other, the (decreasing) order of precedence being character, complex, numeric, integer, logical and raw.

Missing values (NA) and NaN values are regarded as non-comparable even to themselves, so comparisons involving them will always result in NA. Missing values can also result when character strings are compared and one is not valid in the current collation locale.

Language objects such as symbols and calls are deparsed to character strings before comparison.

**Value**

A logical vector indicating the result of the element by element comparison. The elements of shorter vectors are recycled as necessary.

Objects such as arrays or time-series can be compared this way provided they are conformable.

**S4 methods**

These operators are members of the S4 Compare group generic, and so methods can be written for them individually as well as for the group generic (or the Ops group generic), with arguments c(e1, e2).

**Note**

Do not use == and != for tests, such as in if expressions, where you must get a single TRUE or FALSE. Unless you are absolutely sure that nothing unusual can happen, you should use the identical function instead.

For numerical and complex values, remember == and != do not allow for the finite representation of fractions, nor for rounding error. Using all.equal with identical is almost always preferable. See the examples. (This also applies to the other comparison operators.)

These operators are sometimes called as functions as e.g. `<`(x, y): see the description of how argument-matching is done in Ops.

**References**

Collation of character strings is a complex topic. For an introduction see https://en.wikipedia.org/wiki/Collating_sequence. The Unicode Collation Algorithm (http://unicode.org/reports/tr10/) is likely to be increasingly influential. Where available R by default makes use of ICU (http://site.icu-project.org/) for collation (except in a C locale).

**See Also**

factor for the behaviour with factor arguments.

Syntax for operator precedence.

capabilities for whether ICU is available, and icuSetCollate to tune the string collation algorithm when it is.
complex

Examples

```r
x <- stats::rnorm(20)
x < 1
x[x > 0]

x1 <- 0.5 - 0.3
x2 <- 0.3 - 0.1
x1 == x2 # FALSE on most machines
identical(all.equal(x1, x2), TRUE) # TRUE everywhere

# range of most 8-bit charsets, as well as of Latin-1 in Unicode
z <- c(32:126, 160:255)
x <- if(l10n_info()$MBCS) {
  intToUtf8(z, multiple = TRUE)
} else rawToChar(as.raw(z), multiple = TRUE)
## by number
writeLines(strwrap(paste(x, collapse=" "), width = 60))
## by locale collation
writeLines(strwrap(paste(sort(x), collapse=" "), width = 60))
```

Description

Basic functions which support complex arithmetic in R, in addition to the arithmetic operators +, -, \(*\), and \(^\).

Usage

```r
complex(length.out = 0, real = numeric(), imaginary = numeric(),
  modulus = 1, argument = 0)
as.complex(x, ...)
is.complex(x)

Re(z)
Im(z)
Mod(z)
Arg(z)
Conj(z)
```

Arguments

- `length.out` numeric. Desired length of the output vector, inputs being recycled as needed.
- `real` numeric vector.
- `imaginary` numeric vector.
- `modulus` numeric vector.
- `argument` numeric vector.
- `x` an object, probably of mode complex.
z an object of mode complex, or one of a class for which a method has been defined.

... further arguments passed to or from other methods.

Details

Complex vectors can be created with complex. The vector can be specified either by giving its length, its real and imaginary parts, or modulus and argument. (Giving just the length generates a vector of complex zeroes.)

as.complex attempts to coerce its argument to be of complex type: like as.vector it strips attributes including names. Up to R versions 3.2.x, all forms of NA and NaN were coerced to a complex NA, i.e., the NA_complex_ constant, for which both the real and imaginary parts are NA. Since R 3.3.0, typically only objects which are NA in parts are coerced to complex NA, but others with NaN parts, are not. As a consequence, complex arithmetic where only NaN's (but no NA's) are involved typically will not give complex NA but complex numbers with real or imaginary parts of NaN.

Note that is.complex and is.numeric are never both TRUE.

The functions Re, Im, Mod, Arg and Conj have their usual interpretation as returning the real part, imaginary part, modulus, argument and complex conjugate for complex values. The modulus and argument are also called the polar coordinates. If $z = x + iy$ with real $x$ and $y$, for $r = Mod(z) = \sqrt{x^2 + y^2}$, and $\phi = Arg(z)$, $x = r \cdot \cos(\phi)$ and $y = r \cdot \sin(\phi)$. They are all internal generic primitive functions: methods can be defined for them individually or via the Complex group generic.

In addition to the arithmetic operators (see Arithmetic) +, -, *, /, and ^, the elementary trigonometric, logarithmic, exponential, square root and hyperbolic functions are implemented for complex values.

Matrix multiplications (%*%, crossprod, tcrossprod) are also defined for complex matrices (matrix), and so are solve, eigen or svd.

Internally, complex numbers are stored as a pair of double precision numbers, either or both of which can be NaN (including NA, see NA_complex_ and above) or plus or minus infinity.

S4 methods

as.complex is primitive and can have S4 methods set.

Re, Im, Mod, Arg and Conj constitute the S4 group generic Complex and so S4 methods can be set for them individually or via the group generic.

Note

Operations and functions involving complex NaN mostly rely on the C library’s handling of ‘double complex’ arithmetic, which typically returns complex(re=NaN, im=NaN) (but we have not seen a guarantee for that). For + and -, R’s own handling works strictly “coordinate wise”.

Operations involving complex NA, i.e., NA_complex_, return NA_complex_.

Arithmetic; polyroot finds all $n$ complex roots of a polynomial of degree $n$. 
Examples

```r
require(graphics)

0i ^ (-3:3)

matrix(0i^ (-6:5), nrow = 4) # all columns are the same
0 ^ 1i # a complex NaN

## create a complex normal vector
z <- complex(real = stats::rnorm(100), imaginary = stats::rnorm(100))
## or also (less efficiently):
z2 <- 1:2 + 1i*(8:9)

## The Arg(.) is an angle:
zz <- (rep(1:4, len = 9) + 1i*(9:1))/10
zz.shift <- complex(modulus = Mod(zz), argument = Arg(zz) + pi)
plot(zz, xlim = c(-1,1), ylim = c(-1,1), col = "red", asp = 1,
    main = expression(paste("Rotation by ", "", pi == 180^o)))
abline(h = 0, v = 0, col = "blue", lty = 3)
points(zz.shift, col = "orange")

showC <- function(z) noquote(sprintf("(R = %g, I = %g)", Re(z), Im(z)))

## The exact result of this *depends* on the platform, compiler, math-library:
(NpNA <- NaN + NA_complex_) # behaves as 'cplx NA'..
stopifnot(is.na(NpNA), is.na(NA_complex_), is.na(Re(NA_complex_)), is.na(Im(NA_complex_)))
showC(NpNA) # but not always is (shows 'R = NaN, I = NA' on some platforms)
## and this is not TRUE everywhere:
identical(NpNA, NA_complex_)
showC(NA_complex_) # always == (R = NA, I = NA)
```

**conditions**

**Condition Handling and Recovery**

**Description**

These functions provide a mechanism for handling unusual conditions, including errors and warnings.

**Usage**

```r
tryCatch(expr, ..., finally)
withCallingHandlers(expr, ...)

signalCondition(cond)

simpleCondition(message, call = NULL)
simpleError (message, call = NULL)
simpleWarning (message, call = NULL)
simpleMessage (message, call = NULL)

## S3 method for class 'condition'
as.character(x, ...)
```
## S3 method for class 'error'

```r
as.character(x, ...)
```

## S3 method for class 'condition'

```r
print(x, ...)
```

## S3 method for class 'restart'

```r
print(x, ...)
```

conditionCall(c)

## S3 method for class 'condition'

```r
conditionCall(c)
```

conditionMessage(c)

## S3 method for class 'condition'

```r
conditionMessage(c)
```

withRestarts(expr, ...)

computeRestarts(cond = NULL)

findRestart(name, cond = NULL)

invokeRestart(r, ...)

invokeRestartInteractively(r)

isRestart(x)

restartDescription(r)

restartFormals(r)

```r
.signalSimpleWarning(msg, call)
.handleSimpleError(h, msg, call)
.tryResumeInterrupt()
```

### Arguments

- `c` a condition object.
- `call` call expression.
- `cond` a condition object.
- `expr` expression to be evaluated.
- `finally` expression to be evaluated before returning or exiting.
- `h` function.
- `message` character string.
- `msg` character string.
- `name` character string naming a restart.
- `r` restart object.
- `x` object.
- `...` additional arguments; see details below.

### Details

The condition system provides a mechanism for signaling and handling unusual conditions, including errors and warnings. Conditions are represented as objects that contain information about the condition that occurred, such as a message and the call in which the condition occurred. Currently conditions are S3-style objects, though this may eventually change.
Conditions are objects inheriting from the abstract class condition. Errors and warnings are objects inheriting from the abstract subclasses error and warning. The class simpleError is the class used by stop and all internal error signals. Similarly, simpleWarning is used by warning, and simpleMessage is used by message. The constructors by the same names take a string describing the condition as argument and an optional call. The functions conditionMessage and conditionCall are generic functions that return the message and call of a condition.

Conditions are signaled by signalCondition. In addition, the stop and warning functions have been modified to also accept condition arguments.

The function tryCatch evaluates its expression argument in a context where the handlers provided in the ... argument are available. The finally expression is then evaluated in the context in which tryCatch was called; that is, the handlers supplied to the current tryCatch call are not active when the finally expression is evaluated.

Handlers provided in the ... argument to tryCatch are established for the duration of the evaluation of expr. If no condition is signaled when evaluating expr then tryCatch returns the value of the expression.

If a condition is signaled while evaluating expr then established handlers are checked, starting with the most recently established ones, for one matching the class of the condition. When several handlers are supplied in a single tryCatch then the first one is considered more recent than the second. If a handler is found then control is transferred to the tryCatch call that established the handler, the handler found and all more recent handlers are disestablished, the handler is called with the condition as its argument, and the result returned by the handler is returned as the value of the tryCatch call.

Calling handlers are established by withCallingHandlers. If a condition is signaled and the applicable handler is a calling handler, then the handler is called by signalCondition in the context where the condition was signaled but with the available handlers restricted to those below the handler called in the handler stack. If the handler returns, then the next handler is tried; once the last handler has been tried, signalCondition returns NULL.

User interrupts signal a condition of class interrupt that inherits directly from class condition before executing the default interrupt action.

Restarts are used for establishing recovery protocols. They can be established using withRestarts. One pre-established restart is an abort restart that represents a jump to top level. findRestart and computeRestarts find the available restarts. findRestart returns the most recently established restart of the specified name. computeRestarts returns a list of all restarts. Both can be given a condition argument and will then ignore restarts that do not apply to the condition.

invokeRestart transfers control to the point where the specified restart was established and calls the restart's handler with the arguments, if any, given as additional arguments to invokeRestart. The restart argument to invokeRestart can be a character string, in which case findRestart is used to find the restart.

New restarts for withRestarts can be specified in several ways. The simplest is in name = function form where the function is the handler to call when the restart is invoked. Another simple variant is as name = string where the string is stored in the description field of the restart object returned by findRestart; in this case the handler ignores its arguments and returns NULL. The most flexible form of a restart specification is as a list that can include several fields, including handler, description, and test. The test field should contain a function of one argument, a condition, that returns TRUE if the restart applies to the condition and FALSE if it does not; the default function returns TRUE for all conditions.

One additional field that can be specified for a restart is interactive. This should be a function of no arguments that returns a list of arguments to pass to the restart handler. The list could be obtained by interacting with the user if necessary. The function invokeRestartInteractively calls this
function to obtain the arguments to use when invoking the restart. The default interactive method
queries the user for values for the formal arguments of the handler function.

.signalSimpleWarning, .handleSimpleError, and .tryResumeInterrupt are used internally
and should not be called directly.

References

The tryCatch mechanism is similar to Java error handling. Calling handlers are based on Common
Lisp and Dylan. Restarts are based on the Common Lisp restart mechanism.

See Also

stop and warning signal conditions, and try is essentially a simplified version of tryCatch.
assertCondition in package tools texts that conditions are signalled and works with several of
the above handlers.

Examples

tryCatch(1, finally = print("Hello"))
e <- simpleError("test error")
## Not run:
stop(e)
tryCatch(stop(e), finally = print("Hello"))
tryCatch(stop("fred"), finally = print("Hello"))

## End(Not run)
tryCatch(stop(e), error = function(e) e, finally = print("Hello"))
tryCatch(stop("fred"), error = function(e) e, finally = print("Hello"))
withCallingHandlers({ warning("A"); 1+2 }, warning = function(w) { })
## Not run:
{ withRestarts(stop("A"), abort = function() {}); 1 }

## End(Not run)
withRestarts:invokeRestart("foo", 1, 2), foo = function(x, y) {x + y})

demo(error.catching)

## Search for Masked Objects on the Search Path

conflicts reports on objects that exist with the same name in two or more places on the search
path, usually because an object in the user’s workspace or a package is masking a system object of
the same name. This helps discover unintentional masking.

Usage

conflicts(where = search(), detail = FALSE)
Arguments

where A subset of the search path, by default the whole search path.
detail If TRUE, give the masked or masking functions for all members of the search path.

Value

If detail = FALSE, a character vector of masked objects. If detail = TRUE, a list of character vectors giving the masked or masking objects in that member of the search path. Empty vectors are omitted.

Examples

lm <- 1:3
conflicts(, TRUE)
## gives something like
# $.GlobalEnv
# [1] "lm"
#
# $package:base
# [1] "lm"

## Remove things from your "workspace" that mask others:
remove(list = conflicts(detail = TRUE)$.GlobalEnv)
unz(description, filename, open = "", encoding = getOption("encoding"))

pipe(description, open = "", encoding = getOption("encoding"))

fifo(description, open = "", blocking = FALSE, encoding = getOption("encoding"))

socketConnection(host = "localhost", port, server = FALSE, blocking = FALSE, open = "a+", encoding = getOption("encoding"), timeout = getOption("timeout"))

open(con, ...)
## S3 method for class 'connection'
open(con, open = "r", blocking = TRUE, ...)

close(con, ...)
## S3 method for class 'connection'
close(con, type = "rw", ...)

flush(con)

isOpen(con, rw = "")
isIncomplete(con)

Arguments

description character string. A description of the connection: see ‘Details’.

open character string. A description of how to open the connection (if it should be opened initially). See section ‘Modes’ for possible values.

blocking logical. See the ‘Blocking’ section.

encoding The name of the encoding to be assumed. See the ‘Encoding’ section.

raw logical. If true, a ‘raw’ interface is used which will be more suitable for arguments which are not regular files, e.g. character devices. This suppresses the check for a compressed file when opening for text-mode reading, and asserts that the ‘file’ may not be seekable.

method character string, partially matched to c("default", "internal", "wininet", "libcurl"): see ‘Details’.

compression integer in 0–9. The amount of compression to be applied when writing, from none to maximal available. For xzfile can also be negative: see the ‘Compression’ section.

timeout numeric: the timeout (in seconds) to be used for this connection. Beware that some OSes may treat very large values as zero: however the POSIX standard requires values up to 31 days to be supported.

filename a filename within a zip file.

host character string. Host name for the port.

port integer. The TCP port number.

server logical. Should the socket be a client or a server?
connections

con  a connection.
type character string. Currently ignored.
rw  character string. Empty or "read" or "write", partial matches allowed.
... arguments passed to or from other methods.

Details

The first nine functions create connections. By default the connection is not opened (except for a
socketConnection), but may be opened by setting a non-empty value of argument open.

For file the description is a path to the file to be opened or a complete URL (when it is the same
as calling url), or "" (the default) or "clipboard" (see the 'Clipboard' section). Use "stdin" to
refer to the C-level 'standard input' of the process (which need not be connected to anything in a
console or embedded version of R, and is not in RGui on Windows). See also stdin() for the subtly
different R-level concept of stdin.

For url the description is a complete URL including scheme (such as 'http://', 'https://',
'ftp://' or 'file://'). Method "internal" is that available since connections were introduced,
method "wininet" is only available on Windows (it uses the WinInet functions of that OS) and
method "libcurl" (using the library of that name: http://curl.haxx.se/libcurl/) is required
on a Unix-alike but optional on Windows. Method "default" uses method "internal" for 'file:'
URLs and "libcurl" for ftps: URLs. On a Unix-alike it uses "libcurl" for 'http:', 'https:'
and 'ftp:' URLs; on Windows "wininet" for 'http:', 'ftp:' and 'https:' URLs. Proxies can
be specified: see download.file.

For gzfile the description is the path to a file compressed by gzip: it can also open for reading
uncompressed files and those compressed by bzip2, xz or lzma.

For bzfile the description is the path to a file compressed by bzip2.

For xzfile the description is the path to a file compressed by xz (https://en.wikipedia.org/
wiki/Xz) or (for reading only) lzma (https://en.wikipedia.org/wiki/LZMA).

unz reads (only) single files within zip files, in binary mode. The description is the full path to the
zip file, with '.zip' extension if required.

For pipe the description is the command line to be piped to or from. This is run in a shell, on
Windows that specified by the COMSPEC environment variable.

For fifo the description is the path of the fifo. (Support for fifo connections is optional but they
are available on most Unix platforms and on Windows.)

The intention is that file and gzfile can be used generally for text input (from files, 'http://'
and 'https://' URLS) and binary input respectively.

open, close and seek are generic functions: the following applies to the methods relevant to con-
nections.

open opens a connection. In general functions using connections will open them if they are not
open, but then close them again, so to leave a connection open call open explicitly.

close closes and destroys a connection. This will happen automatically in due course (with a
warning) if there is no longer an R object referring to the connection.

A maximum of 128 connections can be allocated (not necessarily open) at any one time. Three of
these are pre-allocated (see stdout). The OS will impose limits on the numbers of connections of
various types, but these are usually larger than 125.

flush flushes the output stream of a connection open for write/append (where implemented, cur-
rently for file and clipboard connections, stdout and stderr).
If for a file or (on most platforms) a fifo connection the description is "", the file/fifo is immediately opened (in "w+" mode unless open = "w+b" is specified) and unlinked from the file system. This provides a temporary file/fifo to write to and then read from.

Value

file, pipe, fifo, url, gzfile, bzfile, xzfile, unz and socketConnection return a connection object which inherits from class "connection" and has a first more specific class.

open and flush return NULL, invisibly.

close returns either NULL or an integer status, invisibly. The status is from when the connection was last closed and is available only for some types of connections (e.g., pipes, files and fifos): typically zero values indicate success. Negative values will result in a warning; if writing, these may indicate write failures and should not be ignored.

isOpen returns a logical value, whether the connection is currently open.

isIncomplete returns a logical value, whether the last read attempt was blocked, or for an output text connection whether there is unflushed output.

URLs

url and file support URL schemes ‘file://’, ‘http://’, ‘https://’ and ‘ftp://’.

method = "libcurl" allows more schemes: exactly which schemes is platform-dependent (see libcurlVersion), but all Unix-alike platforms will support ‘https://’ and most platforms will support ‘ftps://’.

Most methods do not percent-encode special characters such as spaces in ‘http://’ URLs (see URLencode), but it seems the "wininet" method does.

A note on ‘file://’ URLs. The most general form (from RFC1738) is ‘file://host/path/to/file’, but R only accepts the form with an empty host field referring to the local machine.

On a Unix-alike, this is then ‘file:///path/to/file’, where ‘path/to/file’ is relative to ‘/’. So although the third slash is strictly part of the specification not part of the path, this can be regarded as a way to specify the file ‘/path/to/file’. It is not possible to specify a relative path using a file URL.

In this form the path is relative to the root of the filesystem, not a Windows concept. The standard form on Windows is ‘file:///d:/R/repos’: for compatibility with earlier versions of R and Unix versions, any other form is parsed as R as ‘file:///’ plus path_to_file. Also, backslashes are accepted within the path even though RFC1738 does not allow them.

No attempt is made to decode a percent-encoded ‘file:’ URL: call URLdecode if necessary.

All the methods attempt to follow redirected HTTP URLs, but the "internal" method is unable to follow redirections to HTTPS URLs.

Server-side cached data is always accepted.

Function download.file and several contributed packages provide more comprehensive facilities to download from URLs.

Modes

Possible values for the argument open are

"r" or "rt" Open for reading in text mode.

"w" or "wt" Open for writing in text mode.
connections

"a" or "at" Open for appending in text mode.
"rb" Open for reading in binary mode.
"wb" Open for writing in binary mode.
"ab" Open for appending in binary mode.
"r+", "r+b" Open for reading and writing.
"w+", "w+b" Open for reading and writing, truncating file initially.
"a+", "a+b" Open for reading and appending.

Not all modes are applicable to all connections: for example URLs can only be opened for reading. Only file and socket connections can be opened for both reading and writing. An unsupported mode is usually silently substituted.

If a file or fifo is created on a Unix-alike, its permissions will be the maximal allowed by the current setting of umask (see Sys.umask).

For many connections there is little or no difference between text and binary modes. For file-like connections on Windows, translation of line endings (between LF and CRLF) is done in text mode only (but text read operations on connections such as readLines, scan and source work for any form of line ending). Various R operations are possible in only one of the modes: for example pushBack is text-oriented and is only allowed on connections open for reading in text mode, and binary operations such as readBin, load and save can only be done on binary-mode connections.

The mode of a connection is determined when actually opened, which is deferred if open = "" is given (the default for all but socket connections). An explicit call to open can specify the mode, but otherwise the mode will be "r". (gzfile, bzfile and xzfile connections are exceptions, as the compressed file always has to be opened in binary mode and no conversion of line-endings is done even on Windows, so the default mode is interpreted as "rb".) Most operations that need write access or text-only or binary-only mode will override the default mode of a non-yet-open connection.

Append modes need to be considered carefully for compressed-file connections. They do not produce a single compressed stream on the file, but rather append a new compressed stream to the file. Readers may or may not read beyond end of the first stream: currently R does so for gzfile, bzfile and xzfile connections.

Compression

R supports gzip, bzip2 and xz compression (also read-only support for its precursor, 1zma compression).

For reading, the type of compression (if any) can be determined from the first few bytes of the file. Thus for file(raw = FALSE) connections, if open is "", "r" or "rt" the connection can read any of the compressed file types as well as uncompressed files. (Using "rb" will allow compressed files to be read byte-by-byte.) Similarly, gzfile connections can read any of the forms of compression and uncompressed files in any read mode.

(The type of compression is determined when the connection is created if open is unspecified and a file of that name exists. If the intention is to open the connection to write a file with a different form of compression under that name, specify open = "w" when the connection is created or unlink the file before creating the connection.)

For write-mode connections, compress specifies how hard the compressor works to minimize the file size, and higher values need more CPU time and more working memory (up to ca 800Mb for xzfile(compress = 9)). For xzfile negative values of compress correspond to adding the xz argument ‘-e’: this takes more time (double?) to compress but may achieve (slightly) better
connections

Choosing the type of compression involves tradeoffs: gzip, bzip2 and xz are successively less widely supported, need more resources for both compression and decompression, and achieve more compression (although individual files may buck the general trend). Typical experience is that bzip2 compression is 15% better on text files than gzip compression, and xz with maximal compression 30% better. The experience with R save files is similar, but on some large `.rda` files xz compression is much better than the other two. With current computers decompression times even with `compress = 9` are typically modest and reading compressed files is usually faster than uncompressed ones because of the reduction in disc activity.

Encoding

The encoding of the input/output stream of a connection can be specified by name in the same way as it would be given to `iconv`: see that help page for how to find out what encoding names are recognized on your platform. Additionally, "" and "native.enc" both mean the ‘native’ encoding, that is the internal encoding of the current locale and hence no translation is done.

Re-encoding only works for connections in text mode: reading from a connection with re-encoding specified in binary mode will read the stream of bytes, but mixing text and binary mode reads (e.g., mixing calls to `readLines` and `readChar`) is likely to lead to incorrect results.

The encodings "UCS-2LE" and "UTF-16LE" are treated specially, as they are appropriate values for Windows 'Unicode' text files. If the first two bytes are the Byte Order Mark `0xFEFF` then these are removed as some implementations of `iconv` do not accept BOMs. Note that whereas most implementations will handle BOMs using encoding "UCS-2" and choose the appropriate byte order, some (including earlier versions of glibc) will not. There is a subtle distinction between "UTF-16" and "UCS-2" (see https://en.wikipedia.org/wiki/UCS-2: the use of characters in the ‘Supplementary Planes’ which need surrogate pairs is very rare so "UCS-2LE" is an appropriate first choice (as it is more widely implemented).

As from R 3.0.0 the encoding "UTF-8-BOM" is accepted for reading and will remove a Byte Order Mark if present (which it often is for files and webpages generated by Microsoft applications). If a BOM is required (it is not recommended) when writing it should be written explicitly. e.g. by `writeChar("\ufeff", con, eos = NULL) or writeBin(as.raw(c(0xef, 0xbb, 0xbf)), binary_con)`

Encoding names "utf8", "mac" and "macroman" are not portable, and not supported on all current R platforms. "UTF-8" is portable and "macintosh" is the official (and most widely supported) name for ‘Mac Roman’. (As from R 3.4.0, R maps "utf8" to "UTF-8" internally.)

Requesting a conversion that is not supported is an error, reported when the connection is opened. Exactly what happens when the requested translation cannot be done for invalid input is in general undocumented. On output the result is likely to be that up to the error, with a warning. On input, it will most likely be all or some of the input up to the error.

It may be possible to deduce the current native encoding from `Sys.getlocale("LC_CTYPE")`, but not all OSes record it.

Blocking

Whether or not the connection blocks can be specified for file, url (default yes), fifo and socket connections (default not).

In blocking mode, functions using the connection do not return to the R evaluator until the read/write is complete. In non-blocking mode, operations return as soon as possible, so on input they will return with whatever input is available (possibly none) and for output they will return whether or not the write succeeded.
The function `readLines` behaves differently in respect of incomplete last lines in the two modes: see its help page.

Even when a connection is in blocking mode, attempts are made to ensure that it does not block the event loop and hence the operation of GUI parts of R. These do not always succeed, and the whole R process will be blocked during a DNS lookup on Unix, for example.

Most blocking operations on HTTP/FTP URLs and on sockets are subject to the timeout set by `options("timeout")`. Note that this is a timeout for no response, not for the whole operation. The timeout is set at the time the connection is opened (more precisely, when the last connection of that type – ‘http:’, ‘ftp:’ or socket – was opened).

**Fifos**

Fifos default to non-blocking. That follows S version 4 and is probably most natural, but it does have some implications. In particular, opening a non-blocking fifo connection for writing (only) will fail unless some other process is reading on the fifo.

Opening a fifo for both reading and writing (in any mode: one can only append to fifos) connects both sides of the fifo to the R process, and provides an similar facility to `file()`.

**Clipboard**

`file` can be used with `description = "clipboard"` in mode "r" only. This reads the X11 primary selection (see [http://standards.freedesktop.org/clipboards-spec/clipboards-latest.txt](http://standards.freedesktop.org/clipboards-spec/clipboards-latest.txt), which can also be specified as "X11_primary" and the secondary selection as "X11_secondary". On most systems the clipboard selection (that used by 'Copy' from an ‘Edit’ menu) can be specified as "X11_clipboard".

When a clipboard is opened for reading, the contents are immediately copied to internal storage in the connection.

Unix users wishing to write to one of the X11 selections may be able to do so via xclip ([http://sourceforge.net/projects/xclip/](http://sourceforge.net/projects/xclip/)) or xsel ([http://www.vergenet.net/~conrad/software/xsel/](http://www.vergenet.net/~conrad/software/xsel/)), for example by pipe("xclip -i", "w") for the primary selection.

macOS users can use pipe("pbpaste") and pipe("pbcopy", "w") to read from and write to that system’s clipboard.

**Note**

R’s connections are modelled on those in S version 4 (see Chambers, 1998). However R goes well beyond the S model, for example in output text connections and URL, compressed and socket connections. The default open mode in R is "r" except for socket connections. This differs from S, where it is the equivalent of "r+", known as "*".

On (rare) platforms where vsnprintf does not return the needed length of output there is a 100,000 byte output limit on the length of a line for text output on fifo, gzfile, bzfile and xzfile connections: longer lines will be truncated with a warning.

Description

The R Who-is-who, describing who made significant contributions to the development of R.

Usage

```r
contributors()
```

Control

Control Flow

Description

These are the basic control-flow constructs of the R language. They function in much the same way as control statements in any Algol-like language. They are all reserved words.

Usage

```r
if(cond) expr
if(cond) cons.expr else alt.expr

for(var in seq) expr
while(cond) expr
repeat expr
break
next
```
Arguments

cond A length-one logical vector that is not NA. Conditions of length greater than one are currently accepted with a warning, but only the first element is used. An error is signalled instead when the environment variable `_R_CHECK_LENGTH_1_CONDITION_` is set to true. Other types are coerced to logical if possible, ignoring any class.

var A syntactical name for a variable.

seq An expression evaluating to a vector (including a list and an expression) or to a pairlist or NULL. A factor value will be coerced to a character vector.

expr, cons.expr, alt.expr An expression in a formal sense. This is either a simple expression or a so called compound expression, usually of the form `{ expr1 ; expr2 }`.

Details

break breaks out of a for, while or repeat loop; control is transferred to the first statement outside the inner-most loop. next halts the processing of the current iteration and advances the looping index. Both break and next apply only to the innermost of nested loops.

Note that it is a common mistake to forget to put braces (`{ ... }`) around your statements, e.g., after `if(...)` or `for(...). In particular, you should not have a newline between `}` and `else` to avoid a syntax error in entering a if ... else construct at the keyboard or via source. For that reason, one (somewhat extreme) attitude of defensive programming is to always use braces, e.g., for if clauses.

The seq in a for loop is evaluated at the start of the loop; changing it subsequently does not affect the loop. If seq has length zero the body of the loop is skipped. Otherwise the variable var is assigned in turn the value of each element of seq. You can assign to var within the body of the loop, but this will not affect the next iteration. When the loop terminates, var remains as a variable containing its latest value.

Value

if returns the value of the expression evaluated, or NULL invisibly if none was (which may happen if there is no else).

for, while and repeat return NULL invisibly. for sets var to the last used element of seq, or to NULL if it was of length zero.

break and next do not return a value as they transfer control within the loop.

---

**crossprod**

*Matrix Crossproduct*

Description

Given matrices `x` and `y` as arguments, return a matrix cross-product. This is formally equivalent to (but usually slightly faster than) the call `t(x) %*% y` (`crossprod`) or `x %*% t(y)` (`tcrossprod`).

Usage

```r
crossprod(x, y = NULL)
tcrossprod(x, y = NULL)
```

Arguments

- `x, y` numeric or complex matrices (or vectors): `y = NULL` is taken to be the same matrix as `x`. Vectors are promoted to single-column or single-row matrices, depending on the context.

Value

A double or complex matrix, with appropriate `dimnames` taken from `x` and `y`. 

Note
When x or y are not matrices, they are treated as column or row matrices, but their names are usually not promoted to dimnames. Hence, currently, the last example has empty dimnames.

In the same situation, these matrix products (also %*%) are more flexible in promotion of vectors to row or column matrices, such that more cases are allowed, since R 3.2.0.

The propagation of NaN/Inf values, precision, and performance of matrix products can be controlled by options("matprod").

References

See Also
%*% and outer product %o%.

Examples

```r
(z <- crossprod(1:4))  # = sum(1 + 2^2 + 3^2 + 4^2)
drop(z)                # scalar
x <- 1:4; names(x) <- letters[1:4]; x
tcrossprod(as.matrix(x)) # is identical(tcrossprod(as.matrix(x)),
crossprod(t(x)))
tcrossprod(x)          # no dimnames

m <- matrix(1:6, 2,3); v <- 1:3; v2 <- 2:1
stopifnot(identical(tcrossprod(v, m), v %*% t(m)),
           identical(tcrossprod(v, m), crossprod(v, t(m))),
           identical(crossprod(m, v2), t(m) %*% v2))
```

Cstack_info

Report Information on C Stack Size and Usage

Description
Report information on the C stack size and usage (if available).

Usage
Cstack_info()

Details
On most platforms, C stack information is recorded when R is initialized and used for stack-checking. If this information is unavailable, the size will be returned as NA, and stack-checking is not performed.

The information on the stack base address is thought to be accurate on Windows, Linux (using glibc), macOS and FreeBSD but a heuristic is used on other platforms. Because this might be
slightly inaccurate, the current usage could be estimated as negative. (The heuristic is not used on embedded uses of R on platforms where the stack base information is not thought to be accurate.) The ‘evaluation depth’ is the number of nested R expressions currently under evaluation: this has a limit controlled by \texttt{options("expressions")}.

\textbf{Value}

An integer vector. This has named elements

- size: The size of the stack (in bytes), or \texttt{NA} if unknown.
- current: The estimated current usage (in bytes), possibly \texttt{NA}.
- direction: 1 (stack grows down, the usual case) or \texttt{-1} (stack grows up).
- eval_depth: The current evaluation depth (including two calls for the call to \texttt{Cstack_info}).

\textbf{Examples}

\texttt{Cstack_info()}

\begin{verbatim}

cumsum
\end{verbatim}

\textit{Cumulative Sums, Products, and Extremes}

\textbf{Description}

Returns a vector whose elements are the cumulative sums, products, minima or maxima of the elements of the argument.

\textbf{Usage}

\begin{verbatim}
  cumsum(x)
  cumprod(x)
  cummax(x)
  cummin(x)
\end{verbatim}

\textbf{Arguments}

- \texttt{x}: a numeric or complex (not \texttt{cummin} or \texttt{cummax}) object, or an object that can be coerced to one of these.

\textbf{Details}

These are generic functions: methods can be defined for them individually or via the \texttt{Math} group generic.

\textbf{Value}

A vector of the same length and type as \texttt{x} (after coercion), except that \texttt{cumprod} returns a numeric vector for integer input (for consistency with \texttt{*}). Names are preserved.

An \texttt{NA} value in \texttt{x} causes the corresponding and following elements of the return value to be \texttt{NA}, as does integer overflow in \texttt{cumsum} (with a warning).
S4 methods

cumsum and cumprod are S4 generic functions: methods can be defined for them individually or via the Math group generic. cummax and cummin are individually S4 generic functions.

References

Examples

cumsum(1:10)
cumprod(1:10)
cummin(c(3:1, 2:0, 4:2))
cummax(c(3:1, 2:0, 4:2))

curlGetHeaders
Retrieve Headers from URLs

Description

Retrieve the headers for a URL for a supported protocol such as http://, ftp://, https:// and ftps://. An optional function not supported on all platforms.

Usage

curlGetHeaders(url, redirect = TRUE, verify = TRUE)

Arguments

url character string specifying the URL.
redirect logical: should redirections be followed?
verify logical: should certificates be verified as valid and applying to that host?

Details

This reports what curl -I -L or curl -I would report. For a ftp:// URL the 'headers' are a record of the conversation between client and server before data transfer.

Only 500 header lines will be reported: there is a limit of 20 redirections so this should suffice (and even 20 would indicate problems).

It usesgetOption("timeout") for the connection timeout: that defaults to 60 seconds. As this cannot be interrupted you may want to consider a shorter value.

To see all the details of the interaction with the server(s) set options(internet.info = 1).

HTTP[S] servers are allowed to refuse requests to read the headers and some do: this will result in a status of 405.

For possible issues with secure URLs (especially on Windows) see download.file.

There is a security risk in not verifying certificates, but as only the headers are captured it is slight. Usually looking at the URL in a browser will reveal what the problem is (and it may well be machine-specific).
Value

A character vector with integer attribute "status" (the last-received 'status' code). If redirection occurs this will include the headers for all the URLs visited.

See Also

capabilities("libcurl") to see if this is supported.

options HTTPUserAgent and timeout are used.

Examples

## needs Internet access, results vary
curlGetHeaders("http://bugs.r-project.org") ## this redirects to https://
curlGetHeaders("https://httpbin.org/status/404") ## returns status
curlGetHeaders("ftp://cran.r-project.org")

## Not run: ## a not-always-available site:
curlGetHeaders("ftps://test.rebex.net/readme.txt")

## End(Not run)

---

**cut**

#### Convert Numeric to Factor

cut divides the range of \( x \) into intervals and codes the values in \( x \) according to which interval they fall. The leftmost interval corresponds to level one, the next leftmost to level two and so on.

**Usage**

```r
cut(x, ...)
```

**Arguments**

- **x**: a numeric vector which is to be converted to a factor by cutting.
- **breaks**: either a numeric vector of two or more unique cut points or a single number (greater than or equal to 2) giving the number of intervals into which \( x \) is to be cut.
- **labels**: labels for the levels of the resulting category. By default, labels are constructed using "\([a,b]\)" interval notation. If labels = FALSE, simple integer codes are returned instead of a factor.
include.lowest  logical, indicating if an 'x[i]' equal to the lowest (or highest, for right = FALSE) 'breaks' value should be included.

right       logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.

dig.lab     integer which is used when labels are not given. It determines the number of digits used in formatting the break numbers.

ordered_result  logical: should the result be an ordered factor?

... further arguments passed to or from other methods.

Details

When breaks is specified as a single number, the range of the data is divided into breaks pieces of equal length, and then the outer limits are moved away by 0.1% of the range to ensure that the extreme values both fall within the break intervals. (If x is a constant vector, equal-length intervals are created, one of which includes the single value.)

If a labels parameter is specified, its values are used to name the factor levels. If none is specified, the factor level labels are constructed as "[b1, b2]", "(b2, b3]" etc. for right = TRUE and as "[b1, b2]"... if right = FALSE. In this case, dig.lab indicates the minimum number of digits should be used in formatting the numbers b1, b2, .... A larger value (up to 12) will be used if needed to distinguish between any pair of endpoints: if this fails labels such as "Range3" will be used. Formatting is done by formatC.

The default method will sort a numeric vector of breaks, but other methods are not required to and labels will correspond to the intervals after sorting.

As from R 3.2.0,getOption("OutDec") is consulted when labels are constructed for labels = NULL.

Value

A factor is returned, unless labels = FALSE which results in an integer vector of level codes.

Values which fall outside the range of breaks are coded as NA, as are NaN and NA values.

Note

Instead of table(cut(x, br)), hist(x, br, plot = FALSE) is more efficient and less memory hungry. Instead of cut(*, labels = FALSE), findInterval() is more efficient.

References

See Also

split for splitting a variable according to a group factor; factor, tabulate, table, findInterval.
quantile for ways of choosing breaks of roughly equal content (rather than length).
.bincode for a bare-bones version.
**Examples**

```r
Z <- stats::rnorm(10000)
table(cut(Z, breaks = -6:6))
sum(table(cut(Z, breaks = -6:6, labels = FALSE)))
sum(graphics::hist(Z, breaks = -6:6, plot = FALSE)$counts)
cut(rep(1,5), 4) #-- dummy
tx0 <- c(9, 4, 6, 5, 3, 10, 5, 3, 5)
x <- rep(0:8, tx0)
stopifnot(table(x) == tx0)

table( cut(x, b = 8))
table( cut(x, breaks = 3*(-2:5)))
table( cut(x, breaks = 3*(-2:5), right = FALSE))

##--- some values OUTSIDE the breaks :
table(cx <- cut(x, breaks = 2*(0:4)))
table(cxl <- cut(x, breaks = 2*(0:4), right = FALSE))
which(is.na(cx)); x[is.na(cx)] #-- the first 9 values 0
which(is.na(cxl)); x[is.na(cxl)] #-- the last 5 values 8

## Label construction:
y <- stats::rnorm(100)
table(cut(y, breaks = pi/3*(-3:3)))
table(cut(y, breaks = pi/3*(-3:3), dig.lab = 4))
table(cut(y, breaks = 1*(-3:3), dig.lab = 4))
# extra digits don't "harm" here
table(cut(y, breaks = 1*(-3:3), right = FALSE))
# the same, since no exact INT!

## sometimes the default dig.lab is not enough to be avoid confusion:
aaa <- c(1,2,3,4,5,2,3,4,5,6,7)
cut(aaa, 3)
cut(aaa, 3, dig.lab = 4, ordered = TRUE)

## one way to extract the breakpoints
labs <- levels(cut(aaa, 3))
cbind(lower = as.numeric( sub("\((.+),.*", "\1", labs) ),
    upper = as.numeric( sub("[^"\]\*,([^\"]\")\"]", "\"", labs ) ))
```

---

**cut.POSIXt**

*Convert a Date or Date-Time Object to a Factor*

**Description**

Method for `cut` applied to date-time objects.

**Usage**

```r
## S3 method for class 'POSIXt'
cut(x, breaks, labels = NULL, start.on.monday = TRUE, right = FALSE, ...)
```
## S3 method for class 'Date'
cut(x, breaks, labels = NULL, start.on.monday = TRUE,
    right = FALSE, ...)

Arguments

x
an object inheriting from class "POSIXt" or "Date".

breaks
a vector of cut points or number giving the number of intervals which x is to
be cut into or an interval specification, one of "sec", "min", "hour", "day",
"DSTday", "week", "month", "quarter" or "year", optionally preceded by an
integer and a space, or followed by "s". (For "Date" objects only interval spec-
ifications using "day", "week", "month", "quarter" and "year" are allowed.)

labels
labels for the levels of the resulting category. By default, labels are constructed
from the left-hand end of the intervals (which are included for the default value
of right). If labels = FALSE, simple integer codes are returned instead of a
factor.

start.on.monday
logical. If breaks = "weeks", should the week start on Mondays or Sundays?

right, ...
arguments to be passed to or from other methods.

Details

Note that the default for right differs from the default method. Using include.lowest = TRUE
will include both ends of the range of dates.

Using breaks = "quarter" will create intervals of 3 calendar months, with the intervals beginning
on January 1, April 1, July 1 or October 1 (based upon min(x)) as appropriate.

A vector of breaks will be sorted before use: labels should correspond to the sorted vector.

Value

A factor is returned, unless labels = FALSE which returns the integer level codes.

Values which fall outside the range of breaks are coded as NA, as are and NA values.

See Also

seq.POSIXt, seq.Date, cut

Examples

## random dates in a 10-week period
cut(ISOdate(2001, 1, 1) + 70*86400*stats::runif(100), "weeks")
cut(as.Date("2001/1/1") + 70*stats::runif(100), "weeks")

# The standards all have midnight as the start of the day, but some
# people incorrectly interpret it at the end of the previous day ...

tm <- seq(as.POSIXct("2012-06-01 06:00"), by = "6 hours", length.out = 24)
aggregate(1:24, list(day = cut(tm, "days")), mean)

# and a version with midnight included in the previous day:
aggregate(1:24, list(day = cut(tm, "days", right = TRUE)), mean)
Description

Determine the class of an arbitrary R object.

Usage

data.class(x)

Arguments

x

an R object.

Value

character string giving the class of x.

The class is the (first element) of the class attribute if this is non-NULL, or inferred from the object’s dim attribute if this is non-NULL, or mode(x).

Simply speaking, data.class(x) returns what is typically useful for method dispatching. (Or, what the basic creator functions already and maybe eventually all will attach as a class attribute.)

Note

For compatibility reasons, there is one exception to the rule above: When x is integer, the result of data.class(x) is "numeric" even when x is classed.

See Also

class

Examples

x <- LETTERS
data.class(factor(x)) # has a class attribute
data.class(matrix(x, ncol = 13)) # has a dim attribute
data.class(list(x)) # the same as mode(x)
data.class(x) # the same as mode(x)

stopifnot(data.class(1:2) == "numeric") # compatibility "rule"
Description

The function `data.frame()` creates data frames, tightly coupled collections of variables which share many of the properties of matrices and of lists, used as the fundamental data structure by most of R's modeling software.

Usage

```r
data.frame(..., row.names = NULL, check.rows = FALSE,
    check.names = TRUE, fix.empty.names = TRUE,
    stringsAsFactors = default.stringsAsFactors())
```

Arguments

- `...` these arguments are of either the form `value` or `tag = value`. Component names are created based on the tag (if present) or the deparsed argument itself.
- `row.names` NULL or a single integer or character string specifying a column to be used as row names, or a character or integer vector giving the row names for the data frame.
- `check.rows` if TRUE then the rows are checked for consistency of length and names.
- `check.names` logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names and are not duplicated. If necessary they are adjusted (by `make.names`) so that they are.
- `fix.empty.names` logical indicating if arguments which are "unnamed" (in the sense of not being formally called as `someName = arg`) get an automatically constructed name or rather name "". Needs to be set to FALSE even when `check.names` is false if "" names should be kept.
- `stringsAsFactors` logical: should character vectors be converted to factors? The 'factory-fresh' default is TRUE, but this can be changed by setting `options(stringsAsFactors = FALSE)`.

Details

A data frame is a list of variables of the same number of rows with unique row names, given class "data.frame". If no variables are included, the row names determine the number of rows.

The column names should be non-empty, and attempts to use empty names will have unsupported results. Duplicate column names are allowed, but you need to use `check.names = FALSE` for `data.frame` to generate such a data frame. However, not all operations on data frames will preserve duplicated column names: for example matrix-like subsetting will force column names in the result to be unique.

data.frame converts each of its arguments to a data frame by calling `as.data.frame(optional = TRUE)`. As that is a generic function, methods can be written
to change the behaviour of arguments according to their classes: R comes with many such methods. Character variables passed to `data.frame` are converted to factor columns unless protected by `I` or argument `stringsAsFactors` is false. If a list or data frame or matrix is passed to `data.frame` it is as if each component or column had been passed as a separate argument (except for matrices protected by `I`).

Objects passed to `data.frame` should have the same number of rows, but atomic vectors (see `is.vector`), factors and character vectors protected by `I` will be recycled a whole number of times if necessary (including as elements of list arguments).

If row names are not supplied in the call to `data.frame`, the row names are taken from the first component that has suitable names, for example a named vector or a matrix with rownames or a data frame. (If that component is subsequently recycled, the names are discarded with a warning.) If `row.names` was supplied as `NULL` or no suitable component was found the row names are the integer sequence starting at one (and such row names are considered to be ‘automatic’, and not preserved by `as.matrix`).

If row names are supplied of length one and the data frame has a single row, the `row.names` is taken to specify the row names and not a column (by name or number).

Names are removed from vector inputs not protected by `I`.

default.stringsAsFactors is a utility that takes `getOption("stringsAsFactors")` and ensures the result is `TRUE` or `FALSE` (or throws an error if the value is not `NULL`).

Value

A data frame, a matrix-like structure whose columns may be of differing types (numeric, logical, factor and character and so on).

How the names of the data frame are created is complex, and the rest of this paragraph is only the basic story. If the arguments are all named and simple objects (not lists, matrices of data frames) then the argument names give the column names. For an unnamed simple argument, a deparsed version of the argument is used as the name (with an enclosing `I(...)` removed). For a named matrix/list/data frame argument with more than one named column, the names of the columns are the name of the argument followed by a dot and the column name inside the argument: if the argument is unnamed, the argument’s column names are used. For a named or unnamed matrix/list/data frame argument that contains a single column, the column name in the result is the column name in the argument. Finally, the names are adjusted to be unique and syntactically valid unless `check.names = FALSE`.

Note

In versions of R prior to 2.4.0 `row.names` had to be character: to ensure compatibility with such versions of R, supply a character vector as the `row.names` argument.

**Examples**

```r
L3 <- LETTERS[1:3]
fac <- sample(L3, 10, replace = TRUE)
(d <- data.frame(x = 1, y = 1:10, fac = fac))
# The "same" with automatic column names:
data.frame(1, 1:10, sample(L3, 10, replace = TRUE))

is.data.frame(d)

## do not convert to factor, using I() :
(dd <- cbind(d, char = I(letters[1:10])))
rbind(class = sapply(dd, class), mode = sapply(dd, mode))

stopifnot(1:10 == row.names(d)) # {coercion}
```

---

**data.matrix**

*Convert a Data Frame to a Numeric Matrix*

**Description**

Return the matrix obtained by converting all the variables in a data frame to numeric mode and then binding them together as the columns of a matrix. Factors and ordered factors are replaced by their internal codes.

**Usage**

`data.matrix(frame, rownames.force = NA)`

**Arguments**

- `frame`: a data frame whose components are logical vectors, factors or numeric vectors.
- `rownames.force`: logical indicating if the resulting matrix should have character (rather than NULL) rownames. The default, NA, uses NULL rownames if the data frame has 'automatic' row.names or for a zero-row data frame.

**Details**

Logical and factor columns are converted to integers. Any other column which is not numeric (according to `is.numeric`) is converted by `as.numeric` or, for S4 objects, `as(, "numeric")`. If all columns are integer (after conversion) the result is an integer matrix, otherwise a numeric (double) matrix.

**Value**

If `frame` inherits from class "data.frame", an integer or numeric matrix of the same dimensions as `frame`, with dimnames taken from the `row.names` (or NULL, depending on `rownames.force`) and names.

Otherwise, the result of `as.matrix`.
Note

The default behaviour for data frames differs from R < 2.5.0 which always gave the result character rownames.

See Also

`as.matrix`, `data.frame`, `matrix`.

Examples

```r
DF <- data.frame(a = 1:3, b = letters[10:12],
                 c = seq(as.Date("2004-01-01"), by = "week", len = 3),
                 stringsAsFactors = TRUE)
data.matrix(DF[1:2])
data.matrix(DF)
```

---

**date**

*System Date and Time*

Description

Returns a character string of the current system date and time.

Usage

```r
date()
```

Value

The string has the form "Fri Aug 20 11:11:00 1999", i.e., length 24, since it relies on POSIX's `ctime` ensuring the above fixed format. Timezone and Daylight Saving Time are taken account of, but not indicated in the result.

The day and month abbreviations are always in English, irrespective of locale.

`Sys.Date` and `Sys.time`; `Date` and `DateTimeClasses` for objects representing date and time.
Examples

(d <- date())
nchar(d) == 24

## something similar in the current locale
format(Sys.time(), "%a %b %d %H:%M:%S %Y")

---

Dates

Date Class

Description

Description of the class "Date" representing calendar dates.

Usage

## S3 method for class 'Date'
summary(object, digits = 12, ...)

Arguments

- object: An object summarized.
- digits: Number of significant digits for the computations.
- ...: Further arguments to be passed from or to other methods.

Details

Dates are represented as the number of days since 1970-01-01, with negative values for earlier dates. They are always printed following the rules of the current Gregorian calendar, even though that calendar was not in use long ago (it was adopted in 1752 in Great Britain and its colonies).

It is intended that the date should be an integer, but this is not enforced in the internal representation. Fractional days will be ignored when printing. It is possible to produce fractional days via the `mean` method or by adding or subtracting (see `Ops.Date`).

The print methods respect `options("max.print")`.

See Also

- `Sys.Date` for the current date.
- `Ops.Date` for operators on "Date" objects.
- `format.Date` for conversion to and from character strings.
- `axis.Date` and `hist.Date` for plotting.
- `weekdays` for convenience extraction functions.
- `seq.Date, cut.Date, round.Date` for utility operations.
- `DateTimeClasses` for date-time classes.
Examples

(today <- Sys.Date())
format(today, "%d %b %Y") # with month as a word
(tenweeks <- seq(today, length.out=10, by="1 week")] # next ten weeks
weekdays(today)
months(tenweeks)
as.Date(.leap.seconds)

DateTimeClasses

Date-Time Classes

Description

Description of the classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

## S3 method for class 'POSIXct'
print(x, tz = "", usetz = TRUE, ...)

## S3 method for class 'POSIXct'
summary(object, digits = 15, ...)

time + z
z + time
time - z
time1 lop time2

Arguments

x, object an object to be printed or summarized from one of the date-time classes.
tz, usetz for timezone formatting, passed to format.POSIXct.
digits number of significant digits for the computations: should be high enough to
represent the least important time unit exactly.
... further arguments to be passed from or to other methods.
time date-time objects
time1, time2 date-time objects or character vectors. (Character vectors are converted by
as.POSIXct.)
z a numeric vector (in seconds)
lop one of ==, !=, <, <=, > or >=.

Details

There are two basic classes of date/times. Class "POSIXct" represents the (signed) number of
seconds since the beginning of 1970 (in the UTC time zone) as a numeric vector. Class "POSIXlt"
is a named list of vectors representing

sec 0–61: seconds.
min 0–59: minutes.
DateTimeClasses

hour 0–23: hours.
mday 1–31: day of the month
mon 0–11: months after the first of the year.
year years since 1900.
wday 0–6 day of the week, starting on Sunday.
yday 0–365: day of the year.
isdst Daylight Saving Time flag. Positive if in force, zero if not, negative if unknown.
zone (Optional.) The abbreviation for the time zone in force at that time: "" if unknown (but "" might also be used for UTC).
gmtoff (Optional.) The offset in seconds from GMT: positive values are East of the meridian.
Usually NA if unknown, but 0 could mean unknown.

(The last two components are not present for times in UTC and are platform-dependent: they are supported on platforms based on BSD or glibc (including Linux and macOS) and those using the tzcode implementation shipped with R (including Windows). But they are not necessarily set.). Note that the internal list structure is somewhat hidden, as many methods (including length(x), print() and str) apply to the abstract date-time vector, as for "POSIXct". The classes correspond to the POSIX/C99 constructs of 'calendar time' (the time_t data type) and 'local time' (or broken-down time, the struct tm data type), from which they also inherit their names. The components of "POSIXlt" are integer vectors, except sec and zone.

"POSIXct" is more convenient for including in data frames, and "POSIXlt" is closer to human-readable forms. A virtual class "POSIXt" exists from which both of the classes inherit: it is used to allow operations such as subtraction to mix the two classes.

Components wday and yday of "POSIXlt" are for information, and are not used in the conversion to calendar time. However, isdst is needed to distinguish times at the end of DST: typically 1am to 2am occurs twice, first in DST and then in standard time. At all other times isdst can be deduced from the first six values, but the behaviour if it is set incorrectly is platform-dependent.

Logical comparisons and some arithmetic operations are available for both classes. One can add or subtract a number of seconds from a date-time object, but not add two date-time objects. Subtraction of two date-time objects is equivalent to using difftime. Be aware that "POSIXlt" objects will be interpreted as being in the current time zone for these operations unless a time zone has been specified.

"POSIXlt" objects will often have an attribute "tzone", a character vector of length 3 giving the time zone name from the TZ environment variable and the names of the base time zone and the alternate (daylight-saving) time zone. Sometimes this may just be of length one, giving the time zone name.

"POSIXct" objects may also have an attribute "tzone", a character vector of length one. If set to a non-empty value, it will determine how the object is converted to class "POSIXlt" and in particular how it is printed. This is usually desirable, but if you want to specify an object in a particular time zone but to be printed in the current time zone you may want to remove the "tzone" attribute (e.g., by c(x)).

Unfortunately, the conversion is complicated by the operation of time zones and leap seconds (according to this version of R's data, 27 days have been 86401 seconds long so far, the last being on (actually, immediately before) 2017-01-01: the times of the extra seconds are in the object .leap.seconds). The details of this are entrusted to the OS services where possible. It seems that some rare systems used to use leap seconds, but all known current platforms ignore them (as required by POSIX). This is detected and corrected for at build time, so "POSIXct" times used by R do not include leap seconds on any platform.
Using `c` on "POSIXlt" objects converts them to the current time zone, and on "POSIXct" objects drops any "tz" attributes (even if they are all marked with the same time zone).

A few times have specific issues. First, the leap seconds are ignored, and real times such as "2005-12-31 23:59:60" are (probably) treated as the next second. However, they will never be generated by R, and are unlikely to arise as input. Second, on some OSes there is a problem in the POSIX/C99 standard with "1969-12-31 23:59:59 UTC", which is -1 in calendar time and that value is on those OSes also used as an error code. Thus as.POSIXct("1969-12-31 23:59:59", format = "%Y-%m-%d %H:%M:%S", tz = "UTC") may give NA, and hence as.POSIXct("1969-12-31 23:59:59", tz = "UTC") will give "1969-12-31 23:59:00". Other OSes (including the code used by R on Windows) report errors separately and so are able to handle that time as valid.

The print methods respect `options("max.print")`.

### Sub-second Accuracy

Classes "POSIXct" and "POSIXlt" are able to express fractions of a second. (Conversion of fractions between the two forms may not be exact, but will have better than microsecond accuracy.)

Fractional seconds are printed only if `options("digits.secs")` is set: see `strftime`.

### Valid ranges for times

The "POSIXlt" class can represent a very wide range of times (up to billions of years), but such times can only be interpreted with reference to a time zone.

The concept of time zones was first adopted in the nineteenth century, and the Gregorian calendar was introduced in 1582 but not universally adopted until 1927. OS services almost invariably assume the Gregorian calendar and may assume that the time zone that was first enacted for the location was in force before that date. (The earliest legislated time zone seems to have been London on 1847-12-01.) Some OSes assume the previous use of 'local time' based on the longitude of a location within the time zone.

Most operating systems represent POSIXct times as C type long. This means that on 32-bit OSes this covers the period 1902 to 2037. On all known 64-bit platforms and for the code we use on 32-bit Windows, the range of representable times is billions of years: however, not all can convert correctly times before 1902 or after 2037. A few benighted OSes used a unsigned type and so cannot represent times before 1970.

Where possible the platform limits are detected, and outside the limits we use our own C code. This uses the offset from GMT in use either for 1902 (when there was no DST) or that predicted for one of 2030 to 2037 (chosen so that the likely DST transition days are Sundays), and uses the alternate (daylight-saving) time zone only if `isdst` is positive or (if -1) if DST was predicted to be in operation in the 2030s on that day.

Note that there are places (e.g., Rome) whose offset from UTC varied in the years prior to 1902, and these will be handled correctly only where there is OS support.

There is no reason to suppose that the DST rules will remain the same in the future, and indeed the US legislated in 2005 to change its rules as from 2007, with a possible future reversion. So conversions for times more than a year or two ahead are speculative.

### Warnings

Some Unix-like systems (especially Linux ones) do not have environment variable TZ set, yet have internal code that expects it (as does POSIX). We have tried to work around this, but if you get unexpected results try setting TZ. See `Sys.timezone` for valid settings.
Great care is needed when comparing objects of class "POSIXlt". Not only are components and attributes optional; several components may have values meaning ‘not yet determined’ and the same time represented in different time zones will look quite different.

Currently the order of the list components of “POSIXlt” objects must not be changed, as several C-based conversion methods rely on the order for efficiency.

Examples

```r
(z <- Sys.time())  # the current date, as class "POSIXct"
Sys.time() - 3600  # an hour ago
as.POSIXlt(Sys.time(), "GMT")  # the current time in GMT
format(.leap.seconds)  # the leap seconds in your time zone
print(.leap.seconds, tz = "PST8PDT")  # and in Seattle's

## look at *internal* representation of "POSIXlt" :
leapS <- as.POSIXlt(.leap.seconds)
names(leapS) ; is.list(leapS)
## str() "too smart" --> need unclass(.):
utils::str(unclass(leapS), vec.len = 7)
```

---

dcf

*Read and Write Data in DCF Format*

**Description**

Reads or writes an R object from/to a file in Debian Control File format.

**Usage**

```r
read.dcf(file, fields = NULL, all = FALSE, keep.white = NULL)
write.dcf(x, file = "", append = FALSE,
         indent = 0.1 * getOption("width"),
         width = 0.9 * getOption("width"),
         keep.white = NULL)
```
Arguments

- **file**
either a character string naming a file or a connection. ":" indicates output to the console. For `read.dcf` this can name a compressed file (see `gzfile`).

- **fields**
Fields to read from the DCF file. Default is to read all fields.

- **all**
a logical indicating whether in case of multiple occurrences of a field in a record, all these should be gathered. If `all` is false (default), only the last such occurrence is used.

- **keep.white**
a character string with the names of the fields for which whitespace should be kept as is, or `NULL` (default) indicating that there are no such fields. Coerced to character if possible. For fields where whitespace is not to be kept as is, `read.dcf` removes leading and trailing whitespace, and `write.dcf` folds using `strwrap`.

- **x**
the object to be written, typically a data frame. If not, it is attempted to coerce `x` to a data frame.

- **append**
logical. If `TRUE`, the output is appended to the file. If `FALSE`, any existing file of the name is destroyed.

- **indent**
a positive integer specifying the indentation for continuation lines in output entries.

- **width**
a positive integer giving the target column for wrapping lines in the output.

Details

DCF is a simple format for storing databases in plain text files that can easily be directly read and written by humans. DCF is used in various places to store R system information, like descriptions and contents of packages.

The DCF rules as implemented in R are:

1. A database consists of one or more records, each with one or more named fields. Not every record must contain each field. Fields may appear more than once in a record.
2. Regular lines start with a non-whitespace character.
3. Regular lines are of form `tag:value`, i.e., have a name tag and a value for the field, separated by `:` (only the first `:` counts). The value can be empty (i.e., whitespace only).
4. Lines starting with whitespace are continuation lines (to the preceding field) if at least one character in the line is non-whitespace. Continuation lines where the only non-whitespace character is a `.` are taken as blank lines (allowing for multi-paragraph field values).
5. Records are separated by one or more empty (i.e., whitespace only) lines.
6. Individual lines may not be arbitrarily long; prior to R 3.0.2 the length limit was approximately 8191 bytes per line.

Note that `read.dcf(all = FALSE)` reads the file byte-by-byte. This allows a ‘DESCRIPTION’ file to be read and only its ASCII fields used, or its ‘Encoding’ field used to re-encode the remaining fields.

`write.dcf` does not write `NA` fields.

Value

The default `read.dcf(all = FALSE)` returns a character matrix with one row per record and one column per field. Leading and trailing whitespace of field values is ignored unless a field is listed in `keep.white`. If a tag name is specified in the file, but the corresponding value is empty, then an
empty string is returned. If the tag name of a field is specified in fields but never used in a record, then the corresponding value is NA. If fields are repeated within a record, the last one encountered is returned. Malformed lines lead to an error.

For `read.dcf(all = TRUE)` a data frame is returned, again with one row per record and one column per field. The columns are lists of character vectors for fields with multiple occurrences, and character vectors otherwise.

Note that an empty file is a valid DCF file, and `read.dcf` will return a zero-row matrix or data frame.

For `write.dcf`, invisible NULL.

---

### Note

As from R 3.4.0, ‘whitespace’ in all cases includes newlines.

### References

Note that R does not require encoding in UTF-8, which is a recent Debian requirement. Nor does it use the Debian-specific sub-format which allows comment lines starting with ‘#’.

### See Also

- `write.table`.
- `available.packages`, which uses `read.dcf` to read the indices of package repositories.

### Examples

```r
## Create a reduced version of the DESCRIPTION file in package 'splines'
x <- read.dcf(file = system.file("DESCRIPTION", package = "splines"),
              fields = c("Package", "Version", "Title"))
write.dcf(x)

## An online DCF file with multiple records
con <- url("http://cran.r-project.org/src/contrib/PACKAGES")
y <- read.dcf(con, all = TRUE)
close(con)
utils::str(y)
```

---

### debug

**Debug a Function**

Set, unset or query the debugging flag on a function. The `text` and `condition` arguments are the same as those that can be supplied via a call to `browser`. They can be retrieved by the user once the browser has been entered, and provide a mechanism to allow users to identify which breakpoint has been activated.
Usage

debug(fun, text = "", condition = NULL, signature = NULL)
debugonce(fun, text = "", condition = NULL, signature = NULL)
undebug(fun, signature = NULL)
isdebugged(fun, signature = NULL)
debuggingState(on = NULL)

Arguments

fun any interpreted R function.
text a text string that can be retrieved when the browser is entered.
condition a condition that can be retrieved when the browser is entered.
signature an optional method signature. If specified, the method is debugged, rather than its generic.
on logical; a call to the support function debuggingState returns TRUE if debugging is globally turned on, FALSE otherwise. An argument of one or the other of those values sets the state. If the debugging state is FALSE, none of the debugging actions will occur (but explicit browser calls in functions will continue to work).

Details

When a function flagged for debugging is entered, normal execution is suspended and the body of function is executed one statement at a time. A new browser context is initiated for each step (and the previous one destroyed).

At the debug prompt the user can enter commands or R expressions, followed by a newline. The commands are described in the browser help topic.

To debug a function which is defined inside another function, single-step though to the end of its definition, and then call debug on its name.

If you want to debug a function not starting at the very beginning, use trace(..., at = *) or setBreakpoint.

Using debug is persistent, and unless debugging is turned off the debugger will be entered on every invocation (note that if the function is removed and replaced the debug state is not preserved). Use debugonce to enter the debugger only the next time the function is invoked.

To debug an S4 method by explicit signature, use signature. When specified, signature indicates the method of fun to be debugged. Note that debugging is implemented slightly differently for this case, as it uses the trace machinery, rather than the debugging bit. As such, text and condition cannot be specified in combination with a non-null signature. For methods which implement the .local rematching mechanism, the .local closure itself is the one that will be ultimately debugged (see isRematched).

isdebugged returns TRUE if a) signature is NULL and the closure fun has been debugged, or b) signature is not NULL, fun is an S4 generic, and the method of fun for that signature has been debugged. In all other cases, it returns FALSE.

The number of lines printed for the deparsed call when a function is entered for debugging can be limited by setting options(deparse.max.lines).

When debugging is enabled on a byte compiled function then the interpreted version of the function will be used until debugging is disabled.
defunct

Value

deg and undebug invisibly return NULL.
isdebugged returns TRUE if the function or method is marked for debugging, and FALSE otherwise.

See Also

degcall for conveniently debugging methods, browser, trace; traceback to see the stack after an Error: ... message; recover for another debugging approach.

Examples

## Not run:
deg(library)
library(methods)

## End(Not run)
## Not run:
degonce(sample)
## only the first call will be debugged
sample(10, 1)
sample(10, 1)

## End(Not run)

---

Defunct

Marking Objects as Defunct

Description

When a function is removed from R it should be replaced by a function which calls .Defunct.

Usage

. Defunct(new, package = NULL, msg)

Arguments

new
character string: A suggestion for a replacement function.

package
character string: The package to be used when suggesting where the defunct function might be listed.

msg
character string: A message to be printed, if missing a default message is used.

Details

. Defunct is called from defunct functions. Functions should be listed in help("pkg-defunct") for an appropriate pkg, including base (with the alias added to the respective Rd file).

See Also

Deprecated.

base-defunct and so on which list the defunct functions in the packages.
**delayedAssign**

**Description**

`delayedAssign` creates a promise to evaluate the given expression if its value is requested. This provides direct access to the lazy evaluation mechanism used by R for the evaluation of (interpreted) functions.

**Usage**

```r
delayedAssign(x, value, eval.env = parent.frame(1),
              assign.env = parent.frame(1))
```

**Arguments**

- `x`: a variable name (given as a quoted string in the function call)
- `value`: an expression to be assigned to `x`
- `eval.env`: an environment in which to evaluate `value`
- `assign.env`: an environment in which to assign `x`

**Details**

Both `eval.env` and `assign.env` default to the currently active environment.

The expression assigned to a promise by `delayedAssign` will not be evaluated until it is eventually 'forced'. This happens when the variable is first accessed.

When the promise is eventually forced, it is evaluated within the environment specified by `eval.env` (whose contents may have changed in the meantime). After that, the value is fixed and the expression will not be evaluated again.

**Value**

This function is invoked for its side effect, which is assigning a promise to evaluate `value` to the variable `x`.

**See Also**

`substitute`, to see the expression associated with a promise, if `assign.env` is not the `.GlobalEnv`.

**Examples**

```r
msg <- "old"
delayedAssign("x", msg)
substitute(x) # shows only 'x', as it is in the global env.
msg <- "new!"
x # new!

delayedAssign("x", {
  for(i in 1:3)
    cat("yippee!\n")
  10
```
x^2 # yippee
x^2 # simple number

e <- new.env()
delayedAssign("x", pi + 2, assign.env = ne)
## See the promise (without "forcing" (i.e. evaluating) it):
substitute(x, ne) # 'pi + 2'

### Promises in an environment [for advanced users]: ---------------------
e <- (function(x, y = 1, z) environment())(cos, "y", (cat(" HO!
\n"); pi+2))
## How can we look at all promises in an env (w/o forcing them)?
gete <- function(e_)
  lapply(lapply(ls(e_), as.name),
    function(n) eval(substitute(substitute(X, e_), list(X=n)))))

(exps <- gete(e))
sapply(exps, typeof)

(le <- as.list(e)) # evaluates ("force"s) the promises
stopifnot(identical(unname(le), lapply(exps, eval))) # and another "Ho!"

deparse

---

deparse

**Expression Deparsing**

### Description
Turn unevaluated expressions into character strings.

### Usage

```r
deparse(expr, width.cutoff = 60L,
  backtick = mode(expr) %in% c("call", "expression", ",", "function"),
  control = c("keepNA", "keepInteger", "niceNames", "showAttributes"),
  nlines = -1L)
```

### Arguments

- **expr**: any R expression.
- **width.cutoff**: integer in [20, 500] determining the cutoff (in bytes) at which line-breaking is tried.
- **backtick**: logical indicating whether symbolic names should be enclosed in backticks if they do not follow the standard syntax.
- **control**: character vector (or NULL) of deparsing options. See `.deparseOpts`.
- **nlines**: integer: the maximum number of lines to produce. Negative values indicate no limit.
**Details**

This function turns unevaluated expressions (where ‘expression’ is taken in a wider sense than the strict concept of a vector of mode "expression" used in `expression`) into character strings (a kind of inverse to `parse`).

A typical use of this is to create informative labels for data sets and plots. The example shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

The default for the backtick option is not to quote single symbols but only composite expressions. This is a compromise to avoid breaking existing code.

Using `control = "all"` comes closest to making `deparse()` an inverse of `parse()`. However, not all objects are deparse-able even with this option and a warning will be issued if the function recognizes that it is being asked to do the impossible.

Numeric and complex vectors are converted using 15 significant digits: see `as.character` for more details.

`width.cutoff` is a lower bound for the line lengths: deparsing a line proceeds until at least `width.cutoff bytes have been output and e.g. arg = value expressions will not be split across lines.

**Note**

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be deparsed as an attribute.

Deparsing internal structures may not be accurate: for example the graphics display list recorded by `recordPlot` is not intended to be deparsed and `.Internal` calls will be shown as primitive calls.

**References**

**See Also**

`substitute`, `parse`, `expression`.

Quotes for quoting conventions, including backticks.

**Examples**

```r
require(stats); require(graphics)

deparse(args(lm))
deparse(args(lm), width = 500)
myplot <-
  function(x, y) {
    plot(x, y, xlab = deparse(substitute(x)),
         ylab = deparse(substitute(y)))
  }
e <- quote("foo bar")
deparse(e)
deparse(e, backtick = TRUE)
e <- quote("foo bar"+1)
deparse(e)
deparse(e, control = "all")
```
Options for Expression Deparsing

Description
Process the deparsing options for `deparse`, `dput` and `dump`.

Usage
```
.deparseOpts(control)
```

Arguments
- `control` character vector of deparsing options.

Details
`..deparseOpts` is the character vector of possible deparsing options used by `.deparseOpts()`. `.deparseOpts()` is called by `deparse`, `dput` and `dump` to process their `control` argument.

- **"keepInteger"**: Either surround integer vectors by `as.integer()` or use suffix `L`, so they are not converted to type double when parsed. This includes making sure that integer NAs are preserved (via `NA_integer_` if there are no non-NA values in the vector, unless "S_compatible" is set).

- **"quoteExpressions"**: Surround expressions with `quote()`, so they are not evaluated when re-parsed.

- **"showAttributes"**: If the object has attributes (other than a source attribute, see `srcref`), use `structure()` to display them as well as the object value unless the only such attribute is `names` and the "niceNames" option is set. This ("showAttributes") is the default for `deparse` and `dput`.

- **"useSource"**: If the object has a source attribute (`srcref`), display that instead of deparsing the object. Currently only applies to function definitions.

- **"warnIncomplete"**: Some exotic objects such as `environments`, external pointers, etc. can not be deparsed properly. This option causes a warning to be issued if the deparser recognizes one of these situations.
  - Also, the parser in R < 2.7.0 would only accept strings of up to 8192 bytes, and this option gives a warning for longer strings.

- **"keepNA"**: Integer, real and character NAs are surrounded by coercion functions where necessary to ensure that they are parsed to the same type. Since e.g. `NA_real_` can be output in R, this is mainly used in connection with "S_compatible".

- **"niceNames"**: If true, `lists` and atomic vectors with non-NA names (see `names`) are deparsed as e.g., `c(A = 1)` instead of `structure(1, .Names = "A"``), independently of the "showAttributes" setting.

- **"all"**: An abbreviated way to specify all of the options listed above. This is the default for `dump`, and the options used by `edit` (which are fixed).
"delayPromises": Deparse promises in the form <promise: expression> rather than evaluating them. The value and the environment of the promise will not be shown and the deparsed code cannot be sourced.

"S_compatible": Make deparsing as far as possible compatible with S and R < 2.5.0. For compatibility with S, integer values of double vectors are deparsed with a trailing decimal point. Backticks are not used.

"hexNumeric": Real and finite complex numbers are output in ""%a"" format as binary fractions (coded as hexadecimal: see sprintf) with maximal opportunity to be recorded exactly to full precision. Complex numbers with one or both non-finite components are output as if this option were not set.

(This relies on that format being correctly supported: known problems on Windows are worked around as from R 3.1.2.)

"digits17": Real and finite complex numbers are output using format ""%.17g"" which may give more precision than the default (but the output will depend on the platform and there may be loss of precision when read back). Complex numbers with one or both non-finite components are output as if this option were not set.

For the most readable (but perhaps incomplete) display, use control = NULL. This displays the object’s value, but not its attributes. The default in deparse is to display the attributes as well, but not to use any of the other options to make the result parseable. (dput and dump do use more default options, and printing of functions without sources uses c("keepInteger", "keepNA").)

Using control = c("all", "hexNumeric") comes closest to making deparse() an inverse of parse(). However, not all objects are deparse-able even with this option. A warning will be issued if the function recognizes that it is being asked to do the impossible. Also, representing double and complex numbers as decimals may well not be exact.

Only one of "hexNumeric" and "digits17" can be specified.

**Value**

An integer value corresponding to the control options selected.

**Examples**

(iOpt.all <- .deparseOpts("all")) # a four digit integer

## one integer --> vector binary bits
int2bits <- function(x, base = 2L, 
    ndigits = 1 + floor(1e-9 + log(max(x,1), base))) { 
    r <- numeric(ndigits) 
    for (i in ndigits:1) { 
        r[i] <- x%%base 
        if (i > 1L) 
            x <- x%/%base 
    } 
    rev(r) # smallest bit at left
}

int2bits(iOpt.all)

## what options does "all" contain ?
(oa <- ..deparseOpts[-1][int2bits(iOpt.all) == 1])

stopifnot(identical(iOpt.all, .deparseOpts(oa)))
Deprecation

Marking Objects as Deprecated

Description

When an object is about to be removed from R it is first deprecated and should include a call to .Deprecated.

Usage

`.Deprecated(new, package=NULL, msg, old = as.character(sys.call(sys.parent()))[1L])`

Arguments

- `new`: character string: A suggestion for a replacement function.
- `package`: character string: The package to be used when suggesting where the deprecated function might be listed.
- `msg`: character string: A message to be printed, if missing a default message is used.
- `old`: character string specifying the function (default) or usage which is being deprecated.

Details

`.Deprecated(<new name>)` is called from deprecated functions. The original help page for these functions is often available at `help("oldName-deprecated")` (note the quotes). Functions should be listed in `help("pkg-deprecated")` for an appropriate `pkg`, including `base`.

See Also

`Defunct`

`base-deprecated` and so on which list the deprecated functions in the packages.

det

Calculate the Determinant of a Matrix

Description

det calculates the determinant of a matrix. `determinant` is a generic function that returns separately the modulus of the determinant, optionally on the logarithm scale, and the sign of the determinant.

Usage

- `det(x, ...)`
- `determinant(x, logarithm = TRUE, ...)"
Arguments

x numeric matrix: logical matrices are coerced to numeric.

logarithm logical; if TRUE (default) return the logarithm of the modulus of the determinant.

... Optional arguments. At present none are used. Previous versions of det allowed an optional method argument. This argument will be ignored but will not produce an error.

Details

The determinant function uses an LU decomposition and the det function is simply a wrapper around a call to determinant.

Often, computing the determinant is not what you should be doing to solve a given problem.

Value

For det, the determinant of x. For determinant, a list with components

modulus a numeric value. The modulus (absolute value) of the determinant if logarithm is FALSE; otherwise the logarithm of the modulus.

sign integer; either +1 or −1 according to whether the determinant is positive or negative.

Examples

(x <- matrix(1:4, ncol = 2))
unlist(determinant(x))
det(x)
det(print(cbind(1, 1:3, c(2,0,1))))

detach

Detach Objects from the Search Path

Description

Detach a database, i.e., remove it from the search() path of available R objects. Usually this is either a data.frame which has been attached or a package which was attached by library.

Usage

detach(name, pos = 2L, unload = FALSE, character.only = FALSE, force = FALSE)

Arguments

name The object to detach. Defaults to search()[pos]. This can be an unquoted name or a character string but not a character vector. If a number is supplied this is taken as pos.

pos Index position in search() of the database to detach. When name is a number, pos = name is used.
detach

unload

A logical value indicating whether or not to attempt to unload the namespace when a package is being detached. If the package has a namespace and unload is TRUE, then detach will attempt to unload the namespace via unloadNamespace: if the namespace is imported by another namespace or unload is FALSE, no unloading will occur.

character.only

a logical indicating whether name can be assumed to be a character string.

force

logical: should a package be detached even though other attached packages depend on it?

Details

This is most commonly used with a single number argument referring to a position on the search list, and can also be used with a unquoted or quoted name of an item on the search list such as package:tools.

If a package has a namespace, detaching it does not by default unload the namespace (and may not even with unload = TRUE), and detaching will not in general unload any dynamically loaded compiled code (DLLs). Further, registered S3 methods from the namespace will not be removed. If you use library on a package whose namespace is loaded, it attaches the exports of the already loaded namespace. So detaching and re-attaching a package may not refresh some or all components of the package, and is inadvisable.

Value

The return value is invisible. It is NULL when a package is detached, otherwise the environment which was returned by attach when the object was attached (incorporating any changes since it was attached).

Good practice

detach() without an argument removes the first item on the search path after the workspace. It is all too easy to call it too many or too few times, or to not notice that the search path has changed since an attach call.

Use of attach/detach is best avoided in functions (see the help for attach) and in interactive use and scripts it is prudent to detach by name.

Note

You cannot detach either the workspace (position 1) nor the base package (the last item in the search list), and attempting to do so will throw an error.

Unloading some namespaces has undesirable side effects: e.g. unloading grid closes all graphics devices, and on some systems tcltk cannot be reloaded once it has been unloaded and may crash R if this is attempted.

References

See Also

attach, library, search, objects, unloadNamespace, library.dynam.unload.
Examples

```r
require(splines) # package
detach(package:splines)
## or also
library(splines)
pkg <- "package:splines"
detach(pkg, character.only = TRUE)

## careful: do not do this unless 'splines' is not already attached.
library(splines)
detach(2) # 'pos' used for 'name'

## an example of the name argument to attach
## and of detaching a database named by a character vector
attach_and_detach <- function(db, pos = 2)
{
  name <- deparse(substitute(db))
  attach(db, pos = pos, name = name)
  print(search()[pos])
  detach(name, character.only = TRUE)
}
attach_and_detach(women, pos = 3)
```

### diag

**Matrix Diagonals**

**Description**

Extract or replace the diagonal of a matrix, or construct a diagonal matrix.

**Usage**

```r
diag(x = 1, nrow, ncol, names = TRUE)
diag(x) <- value
```

**Arguments**

- `x` a matrix, vector or ID array, or missing.
- `nrow, ncol` optional dimensions for the result when `x` is not a matrix.
- `names` (when `x` is a matrix) logical indicating if the resulting vector, the diagonal of `x`, should inherit `names` from `dimnames(x)` if available.
- `value` either a single value or a vector of length equal to that of the current diagonal. Should be of a mode which can be coerced to that of `x`.

**Details**

diag has four distinct usages:

1. `x` is a matrix, when it extracts the diagonal.
2. `x` is missing and `nrow` is specified, it returns an identity matrix.
3. x is a scalar (length-one vector) and the only argument, it returns a square identity matrix of size given by the scalar.

4. x is a ‘numeric’ (complex, numeric, integer, logical, or raw) vector, either of length at least 2 or there were further arguments. This returns a matrix with the given diagonal and zero off-diagonal entries.

It is an error to specify nrow or ncol in the first case.

Value

If x is a matrix then diag(x) returns the diagonal of x. The resulting vector will have names if the matrix x has matching column and rownames.

The replacement form sets the diagonal of the matrix x to the given value(s).

In all other cases the value is a diagonal matrix with nrow rows and ncol columns (if ncol is not given the matrix is square). Here nrow is taken from the argument if specified, otherwise inferred from x: if that is a vector (or 1D array) of length two or more, then its length is the number of rows, but if it is of length one and neither nrow nor ncol is specified, nrow = as.integer(x).

When a diagonal matrix is returned, the diagonal elements are one except in the fourth case, when x gives the diagonal elements: it will be recycled or truncated as needed, but fractional recycling and truncation will give a warning.

Note

Using diag(x) can have unexpected effects if x is a vector that could be of length one. Use diag(x, nrow = length(x)) for consistent behaviour.

References

See Also

upper.tri, lower.tri, matrix.

Examples

dim(diag(3))
diag(10, 3, 4) # guess what?
all(diag(1:3) == (m <- matrix(0,3,3); diag(m) <- 1:3; m))

## other "numeric"-like diagonal matrices :
diag(c(1i,2i)) # complex
diag(TRUE, 3) # logical
diag(as.raw(1:3)) # raw
(D2 <- diag(2:1, 4)); typeof(D2) # "integer"

require(stats)
## diag(<var-cov-matrix>) = variances
diag(var(M <- cbind(X = 1:5, Y = rnorm(5))))
#-> vector with names "X" and "Y"
rownames(M) <- c(colnames(M), rep("", 3))
M; diag(M) # named as well
diag(M, names = FALSE) # w/o names
**Description**

Returns suitably lagged and iterated differences.

**Usage**

```r
diff(x, ...)
```

## Default S3 method:
```r
diff(x, lag = 1, differences = 1, ...)
```

## S3 method for class 'POSIXt'
```r
diff(x, lag = 1, differences = 1, ...)
```

## S3 method for class 'Date'
```r
diff(x, lag = 1, differences = 1, ...)
```

**Arguments**

- `x`: a numeric vector or matrix containing the values to be differenced.
- `lag`: an integer indicating which lag to use.
- `differences`: an integer indicating the order of the difference.
- `...`: further arguments to be passed to or from methods.

**Details**

diff is a generic function with a default method and ones for classes "ts", "POSIXt" and "Date". 
NA's propagate.

**Value**

If `x` is a vector of length `n` and `differences = 1`, then the computed result is equal to the successive differences `x[(1+lag):n] - x[1:(n-lag)]`.

If `differences` is larger than one this algorithm is applied recursively to `x`. Note that the returned value is a vector which is shorter than `x`.

If `x` is a matrix then the difference operations are carried out on each column separately.

diff.ts, diffinv.
Examples

diff(1:10, 2)
diff(1:10, 2, 2)

x <- cumsum(cumsum(1:10))
diff(x, lag = 2)
diff(x, differences = 2)
diff(.leap.seconds)

difftime Time Intervals / Differences

Description

Time intervals creation, printing, and some arithmetic. The print() method calls these “time differences”.

Usage

time1 - time2
difftime(time1, time2, tz,
    units = c("auto", "secs", "mins", "hours",
        "days", "weeks"))

as.difftime(tim, format = "%X", units = "auto")

## S3 method for class 'difftime'
format(x, ...)
## S3 method for class 'difftime'
units(x)
## S3 replacement method for class 'difftime'
units(x) <- value
## S3 method for class 'difftime'
as.double(x, units = "auto", ...)

## Group methods, notably for round(), signif(), floor(),
## ceiling(), trunc(), abs(); called directly, *not* as Math():
## S3 method for class 'difftime'
Math(x, ...)

Arguments

time1, time2 date-time or date objects.
tz an optional time zone specification to be used for the conversion, mainly for "POSIXt" objects.
units character string. Units in which the results are desired. Can be abbreviated.
value character string. Like units, except that abbreviations are not allowed.
tim character string or numeric value specifying a time interval.
difftime

format character specifying the format of tim: see strftime. The default is a locale-specific time format.

x an object inheriting from class "difftime".

... arguments to be passed to or from other methods.

Details

Function difftime calculates a difference of two date/time objects and returns an object of class "difftime" with an attribute indicating the units. The Math group method provides round, signif, floor, ceiling, trunc, abs, and sign methods for objects of this class, and there are methods for the group-generic (see Ops) logical and arithmetic operations.

If units = "auto", a suitable set of units is chosen, the largest possible (excluding "weeks") in which all the absolute differences are greater than one.

Subtraction of date-time objects gives an object of this class, by calling difftime with units = "auto". Alternatively, as.difftime() works on character-coded or numeric time intervals; in the latter case, units must be specified, and format has no effect.

Limited arithmetic is available on "difftime" objects: they can be added or subtracted, and multiplied or divided by a numeric vector. In addition, adding or subtracting a numeric vector by a "difftime" object implicitly converts the numeric vector to a "difftime" object with the same units as the "difftime" object. There are methods for mean and sum (via the Summary group generic), and diff via diff.default building on the "difftime" method for arithmetic, notably -.

The units of a "difftime" object can be extracted by the units function, which also has a replacement form. If the units are changed, the numerical value is scaled accordingly. The replacement version keeps attributes such as names and dimensions.

Note that units = "days" means a period of 24 hours, hence takes no account of Daylight Savings Time. Differences in objects of class "Date" are computed as if in the UTC time zone.

The as.double method returns the numeric value expressed in the specified units. Using units = "auto" means the units of the object.

The format method simply formats the numeric value and appends the units as a text string.

Note

Units such as "months" are not possible as they are not of constant length. To create intervals of months, quarters or years use seq.Date or seq.POSIXt.

See Also

DateTimeClasses.

Examples

(z <- Sys.time() - 3600)
Sys.time() - z # just over 3600 seconds.

## time interval between release days of R 1.2.2 and 1.2.3.
150date(2001, 4, 26) - 150date(2001, 2, 26)

as.difftime(c("0:3:20", "11:23:15"))
as.difftime(c("3:20", "23:15", "2:"), format = "%H:%M") # 3rd gives NA
(z <- as.difftime(c(0,30,60), units = "mins"))
as.numeric(z, units = "secs")
as.numeric(z, units = "hours")
format(z)

---

**dim**  
*Dimensions of an Object*

**Description**
Retrieve or set the dimension of an object.

**Usage**
dim(x)
dim(x) <- value

**Arguments**
x  
an R object, for example a matrix, array or data frame.
value  
For the default method, either NULL or a numeric vector, which is coerced to integer (by truncation).

**Details**
The functions dim and dim<- are *internal generic primitive* functions.
dim has a method for data.frames, which returns the lengths of the row.names attribute of x and of x (as the numbers of rows and columns respectively).

**Value**
For an array (and hence in particular, for a matrix) dim retrieves the dim attribute of the object. It is NULL or a vector of mode integer.
The replacement method changes the "dim" attribute (provided the new value is compatible) and removes any "dimnames" and "names" attributes.

**References**

**See Also**
ncol, nrow and dimnames.

**Examples**
x <- 1:12 ; dim(x) <- c(3,4)
x

# simple versions of nrow and ncol could be defined as follows
nrow@ <- function(x) dim(x)[1]
ncol@ <- function(x) dim(x)[2]
Dimnames of an Object

Description

Retrieve or set the dimnames of an object.

Usage

dimnames(x)
dimnames(x) <- value

provideDimnames(x, sep = "", base = list(LETTERS), unique = TRUE)

Arguments

x an R object, for example a matrix, array or data frame.
value a possible value for dimnames(x): see the ‘Value’ section.
sep a character string, used to separate base symbols and digits in the constructed
dimnames.
base a non-empty list of character vectors. The list components are used in turn
(and recycled when needed) to construct replacements for empty dimnames
components. See also the examples.
unique logical indicating that the dimnames constructed are unique within each dimen-
sion in the sense of make.unique.

Details

The functions dimnames and dimnames<- are generic.

For an array (and hence in particular, for a matrix), they retrieve or set the dimnames attribute (see attributes) of the object. A list value can have names, and these will be used to label the dimensions of the array where appropriate.

The replacement method for arrays/matrices coerces vector and factor elements of value to character, but does not dispatch methods for as.character. It coerces zero-length elements to NULL, and a zero-length list to NULL. If value is a list shorter than the number of dimensions, it is extended with NULLs to the needed length.

Both have methods for data frames. The dimnames of a data frame are its row.names and its names. For the replacement method each component of value will be coerced by as.character.

For a 1D matrix the names are the same thing as the (only) component of the dimnames.

Both are primitive functions.

provideDimnames(x) provides dimnames where “missing”, such that its result has character dimnames for each component. If unique is true as by default, they are unique within each component via make.unique(*, sep=sep).
Value

The dimnames of a matrix or array can be NULL (which is not stored) or a list of the same length as \texttt{dim(x)}. If a list, its components are either NULL or a character vector with positive length of the appropriate dimension of \texttt{x}. The list can have names. It is possible that all components are NULL: such dimnames may get converted to NULL.

For the "\texttt{data.frame}" method both dimnames are character vectors, and the rownames must contain no duplicates nor missing values.

\texttt{provideDimnames(x)} returns \texttt{x}, with "NULL - free" dimnames, i.e. each component a character vector of correct length.

Note

Setting components of the dimnames, e.g., \texttt{dimnames(A)[[1]] <- value} is a common paradigm, but note that it will not work if the value assigned is NULL. Use \texttt{rownames} instead, or (as it does) manipulate the whole dimnames list.

References

See Also

\texttt{rownames}, \texttt{colnames}; \texttt{array}, \texttt{matrix}, \texttt{data.frame}.

Examples

```r
## simple versions of rownames and colnames
## could be defined as follows
rownames0 <- function(x) dimnames(x)[[1]]
colnames0 <- function(x) dimnames(x)[[2]]

(dn <- dimnames(A <- provideDimnames(N <- array(1:24, dim = 2:4))))
A0 <- A; dimnames(A)[2:3] <- list(NULL)
stopifnot(identical(A0, provideDimnames(A)))
str <- function(x) utils::str(dimnames(x))
str(provideDimnames(A, base= list(letters[-(1:9)], tail(LETTERS))))
str(provideDimnames(N, base= list(letters[-(1:9)], tail(LETTERS)))) # recycling
str(provideDimnames(A, base= list(c("AA","BB")))) # recycling on both levels
## set "empty dimnames":
provideDimnames(rbind(1, 2:3), base = list(""), unique=FALSE)
```

---

**do.call**

**Execute a Function Call**

**Description**

do.call constructs and executes a function call from a name or a function and a list of arguments to be passed to it.

**Usage**

do.call(what, args, quote = FALSE, envir = parent.frame())
do.call

Arguments

what
either a function or a non-empty character string naming the function to be called.

args
a list of arguments to the function call. The names attribute of args gives the argument names.

quote
a logical value indicating whether to quote the arguments.

envir
an environment within which to evaluate the call. This will be most useful if what is a character string and the arguments are symbols or quoted expressions.

Details

If quote is FALSE, the default, then the arguments are evaluated (in the calling environment, not in envir). If quote is TRUE then each argument is quoted (see quote) so that the effect of argument evaluation is to remove the quotes – leaving the original arguments unevaluated when the call is constructed.

The behavior of some functions, such as substitute, will not be the same for functions evaluated using do.call as if they were evaluated from the interpreter. The precise semantics are currently undefined and subject to change.

Value

The result of the (evaluated) function call.

Warning

This should not be used to attempt to evade restrictions on the use of .Internal and other non-API calls.

References

See Also

call which creates an unevaluated call.

Examples

do.call("complex", list(imag = 1:3))

## if we already have a list (e.g., a data frame)
## we need c() to add further arguments
tmp <- expand.grid(letters[1:2], 1:3, c("+", "-"))
do.call("paste", c(tmp, sep = ""))

do.call(paste, list(as.name("A"), as.name("B")), quote = TRUE)

## examples of where objects will be found.
A <- 2
f <- function(x) print(x^2)
env <- new.env()
assign("A", 10, envir = env)
assign("f", f, envir = env)
f <- function(x) print(x)
f(A) # 2
do.call("f", list(A)) # 2
do.call("f", list(A), envir = env) # 4
do.call(f, list(A), envir = env) # 2
do.call("f", list(quote(A)), envir = env) # 100
do.call(f, list(quote(A)), envir = env) # 10
do.call("f", list(as.name("A")), envir = env) # 100
eval(call("f", A)) # 2
eval(call("f", quote(A))) # 2
eval(call("f", A), envir = env) # 4
eval(call("f", quote(A)), envir = env) # 100

dontCheck

Identity Function to Suppress Checking

Description

The dontCheck function is the same as identity, but is interpreted by R CMD check code analysis as a directive to suppress checking of x. Currently this is only used by checkFF(registration = TRUE) when checking the .NAME argument of foreign function calls.

Usage
dontCheck(x)

Arguments

x

an R object.

See Also

suppressForeignCheck which explains why that and dontCheck are undesirable and should be avoided if at all possible.

dots

..., .1, etc used in Functions

Description

... and .1...2 etc are used to refer to arguments passed down from a calling function. These (and the following) can only be used inside a function which has ... among it formal arguments.

...elt(n) is a functional way to get ..<n> and basically the same as eval(paste0("..", n)), just more elegant and efficient. Note that switch(n, ...) is very close, differing by returning NULL invisibly instead of an error when n is zero or too large.

...length() returns the number of expressions in .... This is the same as length(list(...)) but without evaluating the expressions in ... (which happens with list(...)).
Usage

...length()
...elt(n)

Arguments

n a positive integer, not larger than the number of expressions in ... , which is the same as ...length() which is the same as length(list(...)), but the latter evaluates all expressions in ....

See Also

... and ..1, ..2 are reserved words in R, see Reserved.

For more, see the 'Introduction to R' manual for usage of these syntactic elements, and dotsMethods for their use in formal (S4) methods.

Examples

tst <- function(n, ...) ...elt(n)
tst(1, pi=pi*0:1, 2:4) ## [1] 0.000000 3.141593
tst(2, pi=pi*0:1, 2:4) ## [1] 2 3 4
tst(tst(1)) # -> Error about '...' not containing an element.

tst.dl <- function(x, ...) ...length()
tst.dl(1:10) # 0 (because the first argument is 'x')
tst.dl(4, 5) # 1
tst.dl(4, 5, 6) # 2 namely '5, 6'
tst.dl(4, 5, 6, 7, sin(1:10), "foo"/"bar") # 5. Note: no evaluation!
Details
double creates a double-precision vector of the specified length. The elements of the vector are all
equal to 0. It is identical to numeric.
as. double is a generic function. It is identical to as.numeric. Methods should return an object of
base type "double".
is. double is a test of double type.
R has no single precision data type. All real numbers are stored in double precision format. The
functions as.single and single are identical to as.double and double except they set the attr-

Value
double creates a double-precision vector of the specified length. The elements of the vector are all
equal to 0.
as. double attempts to coerce its argument to be of double type: like as.vector it strips attributes
including names. (To ensure that an object is of double type without stripping attributes, use
storage.mode.) Character strings containing optional whitespace followed by either a decimal
representation or a hexadecimal representation (starting with 0x or 0X) can be converted, as can
special values such as "NA", "NaN", "Inf" and "Infinity", irrespective of case.
as. double for factors yields the codes underlying the factor levels, not the numeric representation
of the labels, see also factor.
is. double returns TRUE or FALSE depending on whether its argument is of double type or not.

Double-precision values
All R platforms are required to work with values conforming to the IEC 60559 (also known as IEEE
754) standard. This basically works with a precision of 53 bits, and represents to that precision a
range of absolute values from about $2 \times 10^{-308}$ to $2 \times 10^{308}$. It also has special values NaN (many
of them), plus and minus infinity and plus and minus zero (although R acts as if these are the same).
There are also denormalized (or subnormal) numbers with absolute values above or below the
range given above but represented to less precision.

Note on names
It is a historical anomaly that R has two names for its floating-point vectors, double and numeric
(and formerly had real).
double is the name of the type. numeric is the name of the mode and also of the implicit class. As
an S4 formal class, use "numeric".
The potential confusion is that R has used mode "numeric" to mean ‘double or integer’, which
conflicts with the S4 usage. Thus is.numeric tests the mode, not the class, but as.numeric (which
is identical to as.double) coerces to the class.

http://grouper.ieee.org/groups/754/ for links to information on the standards.

See Also

integer, numeric, storage.mode.

Examples

is.double(1)
all(double(3) == 0)

dput

**Write an Object to a File or Recreate it**

Description

Writes an ASCII text representation of an R object to a file or connection, or uses one to recreate the object.

Usage

\[
dput(x, file = ",", control = c("keepNA", "keepInteger", "niceNames", "showAttributes"))
\]

dget(file, keep.source = FALSE)

Arguments

- \textbf{x} an object.
- \textbf{file} either a character string naming a file or a \texttt{connection}. "" indicates output to the console.
- \textbf{control} character vector indicating deparsing options. See .\texttt{deparseOpts} for their description.
- \textbf{keep.source} logical: should the source formatting be retained when parsing functions, if possible?

Details

dput opens file and deparses the object \texttt{x} into that file. The object name is not written (unlike \texttt{dump}). If \texttt{x} is a function the associated environment is stripped. Hence scoping information can be lost.

Deparsing an object is difficult, and not always possible. With the default \texttt{control}, \texttt{dput()} attempts to deparse in a way that is readable, but for more complex or unusual objects (see \texttt{dump}, not likely...
to be parsed as identical to the original. Use control = "all" for the most complete deparsing; use control = NULL for the simplest deparsing, not even including attributes.

dput will warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

To display saved source rather than deparsing the internal representation include "useSource" in control. R currently saves source only for function definitions. If you do not care about source representation (e.g., for a data object), for speed set options(keep.source = FALSE) when calling source.

Value

For dput, the first argument invisibly.

For dget, the object created.

Note

This is not a good way to transfer objects between R sessions. dump is better, but the function save is designed to be used for transporting R data, and will work with R objects that dput does not handle correctly as well as being much faster.

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be written as an attribute.

References

See Also

deparse, dump, write.

Examples

```r
## Write an ASCII version of function mean to the file "foo"
dput(mean, "foo")
## And read it back into 'bar'
bar <- dget("foo")
## Create a function with comments
baz <- function(x) {
  # Subtract from one
  1-x
}
## and display it
dput(baz)
## and now display the saved source
dput(baz, control = "useSource")

## Numeric values:
xx <- pi^(1:3)
dput(xx)
dput(xx, control = "digits17")
dput(xx, control = "hexNumeric"
xx, "foo", control = "digits17")
dput(xx, "foo"); dget("foo") - xx # slight rounding on all platforms
dput(xx, "foo", control = "digits17")
```
drop

Description

Delete the dimensions of an array which have only one level.

Usage

drop(x)

Arguments

x an array (including a matrix).

Value

If x is an object with a dim attribute (e.g., a matrix or array), then drop returns an object like x, but with any extents of length one removed. Any accompanying dimnames attribute is adjusted and returned with x: if the result is a vector the names are taken from the dimnames (if any). If the result is a length-one vector, the names are taken from the first dimension with a dimname.

Array subsetting ([]) performs this reduction unless used with drop = FALSE, but sometimes it is useful to invoke drop directly.

See Also

drop1 which is used for dropping terms in models.

Examples

dim(drop(array(1:12, dim = c(1,3,1,1,2,1,2)))) # = 3 2 2
drop(1:3 %*% 2:4)  # scalar product
**droplevels**

*Drop Unused Levels from Factors*

**Description**

The function `droplevels` is used to drop unused levels from a `factor` or, more commonly, from factors in a data frame.

**Usage**

```r
## S3 method for class 'factor'
droplevels(x, exclude = if(anyNA(levels(x))) NULL else NA, ...)
## S3 method for class 'data.frame'
droplevels(x, except, exclude, ...)
```

**Arguments**

- `x`: an object from which to drop unused factor levels.
- `exclude`: passed to `factor()`; factor levels which should be excluded from the result even if present. Note that this was *implicitly* `NA` in R <= 3.3.1 which did drop `NA` levels even when present in `x`, contrary to the documentation. The current default is compatible with `x[, drop=TRUE]`.
- `...`: further arguments passed to methods
- `except`: indices of columns from which *not* to drop levels

**Details**

The method for class “factor” is currently equivalent to `factor(x, exclude=exclude)`. For the data frame method, you should rarely specify `exclude` “globally” for all factor columns; rather the default uses the same factor-specific `exclude` as the factor method itself.

The `except` argument follow the usual indexing rules.

**Value**

`droplevels` returns an object of the same class as `x`

**Note**

This function was introduced in R 2.12.0. It is primarily intended for cases where one or more factors in a data frame contains only elements from a reduced level set after subsetting. (Notice that subsetting does *not* in general drop unused levels). By default, levels are dropped from all factors in a data frame, but the `except` argument allows you to specify columns for which this is not wanted.

**See Also**

- `subset` for subsetting data frames. `factor` for definition of factors. `drop` for dropping array dimensions. `drop1` for dropping terms from a model. `.[factor` for subsetting of factors.
Examples

```r
aq <- transform(airquality, Month = factor(Month, labels = month.abb[5:9]))
aq <- subset(aq, Month != "Jul")
table(aq$Month)
table(droplevels(aq)$Month)
```

Description

This function takes a vector of names of R objects and produces text representations of the objects on a file or connection. A dump file can usually be sourced into another R session.

Usage

```r
dump(list, file = "dumpdata.R", append = FALSE,
    control = "all", envir = parent.frame(), evaluate = TRUE)
```

Arguments

- **list**: character vector. The names of one or more R objects to be dumped.
- **file**: either a character string naming a file or a connection. "" indicates output to the console.
- **append**: if TRUE and file is a character string, output will be appended to file; otherwise, it will overwrite the contents of file.
- **control**: character vector indicating deparsing options. See `.deparseOpts` for their description.
- **envir**: the environment to search for objects.
- **evaluate**: logical. Should promises be evaluated?

Details

If some of the objects named do not exist (in scope), they are omitted, with a warning. If file is a file and no objects exist then no file is created.

Sourcing may not produce an identical copy of dumped objects. A warning is issued if it is likely that problems will arise, for example when dumping exotic or complex objects (see the Note).

dump will also warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

A dump file can be sourced into another R (or perhaps S) session, but the function `save` is designed to be used for transporting R data, and will work with R objects that dump does not handle. For maximal reproducibility use `control = c("all", "hexNumeric")`.

To produce a more readable representation of an object, use `control = NULL`. This will skip attributes, and will make other simplifications that make source less likely to produce an identical copy. See `deparse` for details.

To deparse the internal representation of a function rather than displaying the saved source, use `control = c("keepInteger", "warnIncomplete", "keepNA")`. This will lose all formatting and comments, but may be useful in those cases where the saved source is no longer correct.
Promises will normally only be encountered by users as a result of lazy-loading (when the default `evaluate = TRUE` is essential) and after the use of `delayedAssign`, when `evaluate = FALSE` might be intended.

**Value**

An invisible character vector containing the names of the objects which were dumped.

**Note**

As `dump` is defined in the base namespace, the `base` package will be searched before the global environment unless `dump` is called from the top level prompt or the `envir` argument is given explicitly.

To avoid the risk of a source attribute becoming out of sync with the actual function definition, the source attribute of a function will never be dumped as an attribute.

Currently environments, external pointers, weak references and objects of type S4 are not deparsed in a way that can be sourced. In addition, language objects are deparsed in a simple way whatever the value of control, and this includes not dumping their attributes (which will result in a warning).

**References**

**See Also**

`dput`, `dget`, `write`,

`save` for a more reliable way to save R objects.

**Examples**

```r
x <- 1; y <- 1:10
dump(ls(pattern = '^xyz'), "xyz.Rdmped")
print(.Last.value)
unlink("xyz.Rdmped")
```

---

**duplicated**

**Determine Duplicate Elements**

duplicated() determines which elements of a vector or data frame are duplicates of elements with smaller subscripts, and returns a logical vector indicating which elements (rows) are duplicates.

`anyDuplicated(.)` is a “generalized” more efficient shortcut for `any(duplicated(.))`. 
duplicated

Usage
duplicated(x, incomparables = FALSE, ...)

## Default S3 method:
duplicated(x, incomparables = FALSE,
fromLast = FALSE, nmax = NA, ...)

## S3 method for class 'array'
duplicated(x, incomparables = FALSE, MARGIN = 1,
fromLast = FALSE, ...)

anyDuplicated(x, incomparables = FALSE, ...)

## Default S3 method:
anyDuplicated(x, incomparables = FALSE,
fromLast = FALSE, ...)

## S3 method for class 'array'
anyDuplicated(x, incomparables = FALSE,
MARGIN = 1, fromLast = FALSE, ...)

Arguments

x a vector or a data frame or an array or NULL.
incomparables a vector of values that cannot be compared. FALSE is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as x.
fromLast logical indicating if duplication should be considered from the reverse side, i.e., the last (or rightmost) of identical elements would correspond to duplicated = FALSE.
nmax the maximum number of unique items expected (greater than one).
... arguments for particular methods.
MARGIN the array margin to be held fixed: see apply, and note that MARGIN = 0 may be useful.

Details

These are generic functions with methods for vectors (including lists), data frames and arrays (including matrices).

For the default methods, and whenever there are equivalent method definitions for duplicated and anyDuplicated, anyDuplicated(x, ...) is a “generalized” shortcut for any(duplicated(x, ...)), in the sense that it returns the index 1 of the first duplicated entry x[i] if there is one, and 0 otherwise. Their behaviours may be different when at least one of duplicated and anyDuplicated has a relevant method.

duplicated(x, fromLast = TRUE) is equivalent to but faster than rev(duplicated(rev(x))).

The data frame method works by pasting together a character representation of the rows separated by \r, so may be imperfect if the data frame has characters with embedded carriage returns or columns which do not reliably map to characters.

The array method calculates for each element of the sub-array specified by MARGIN if the remaining dimensions are identical to those for an earlier (or later, when fromLast = TRUE) element (in row-major order). This would most commonly be used to find duplicated rows (the default) or columns
duplicated

(with $\text{MARGIN} = 2$). Note that $\text{MARGIN} = 0$ returns an array of the same dimensionality attributes as $x$.

Missing values ("NA") are regarded as equal, numeric and complex ones differing from NaN; character strings will be compared in a “common encoding”; for details, see $\text{match}$ (and $\text{unique}$) which use the same concept.

Values in incomparables will never be marked as duplicated. This is intended to be used for a fairly small set of values and will not be efficient for a very large set.

When used on a data frame with more than one column, or an array or matrix when comparing dimensions of length greater than one, this tests for identity of character representations. This will catch people who unwisely rely on exact equality of floating-point numbers!

Except for factors, logical and raw vectors the default $\text{nmax} = \text{NA}$ is equivalent to $\text{nmax} = \text{length}(x)$. Since a hash table of size $8\times\text{nmax}$ bytes is allocated, setting $\text{nmax}$ suitably can save large amounts of memory. For factors it is automatically set to the smaller of $\text{length}(x)$ and the number of levels plus one (for NA). If $\text{nmax}$ is set too small there is liable to be an error: $\text{nmax} = 1$ is silently ignored.

Long vectors are supported for the default method of duplicated, but may only be usable if $\text{nmax}$ is supplied.

Value

duplicated(): For a vector input, a logical vector of the same length as $x$. For a data frame, a logical vector with one element for each row. For a matrix or array, and when $\text{MARGIN} = 0$, a logical array with the same dimensions and dimnames.

anyDuplicated(): an integer or real vector of length one with value the 1-based index of the first duplicate if any, otherwise 0.

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see $\text{vector}$) or differ only in their attributes. In the worst case it is $O(n^2)$.

References

See Also

$\text{unique}$.

Examples

```r
x <- c(9:20, 1:5, 3:7, 0:8)
## extract unique elements
(xu <- x[!duplicated(x)])
## similar, same elements but different order:
(xu2 <- x[!duplicated(x, fromLast = TRUE)])
## xu == unique(x) but unique(x) is more efficient
stopifnot(identical(xu, unique(x)),
          identical(xu2, unique(x, fromLast = TRUE)))

x[140:143]
```

dyn.load

155

duplicated(iris3, MARGIN = c(1, 3))
anyDuplicated(iris) ## 143
anyDuplicated(x)
anyDuplicated(x, fromLast = TRUE)

dyn.load

Foreign Function Interface

Description
Load or unload DLLs (also known as shared objects), and test whether a C function or Fortran
subroutine is available.
Usage
dyn.load(x, local = TRUE, now = TRUE, ...)
dyn.unload(x)
is.loaded(symbol, PACKAGE = "", type = "")
Arguments
x

a character string giving the pathname to a DLL, also known as a dynamic shared
object. (See ‘Details’ for what these terms mean.)

local

a logical value controlling whether the symbols in the DLL are stored in their
own local table and not shared across DLLs, or added to the global symbol table.
Whether this has any effect is system-dependent.

now

a logical controlling whether all symbols are resolved (and relocated) immediately the library is loaded or deferred until they are used. This control is useful
for developers testing whether a library is complete and has all the necessary
symbols, and for users to ignore missing symbols. Whether this has any effect
is system-dependent.

...

other arguments for future expansion.

symbol

a character string giving a symbol name.

PACKAGE

if supplied, confine the search for the name to the DLL given by this argument
(plus the conventional extension, ‘.so’, ‘.sl’, ‘.dll’, . . . ). This is intended to
add safety for packages, which can ensure by using this argument that no other
package can override their external symbols. This is used in the same way as in

type

The type of symbol to look for: can be any ("", the default), "Fortran", "Call"
or "External".

Details
The objects dyn.load loads are called ‘dynamically loadable libraries’ (abbreviated to ‘DLL’) on
all platforms except macOS, which uses the term for a different sort of object. On Unix-alikes
they are also called ‘dynamic shared objects’ (‘DSO’), or ‘shared objects’ for short. (The POSIX
standards use ‘executable object file’, but no one else does.)


See ‘See Also’ and the ‘Writing R Extensions’ and ‘R Installation and Administration’ manuals for how to create and install a suitable DLL.

Unfortunately a very few platforms (e.g., Compaq Tru64) do not handle the \texttt{PACKAGE} argument correctly, and may incorrectly find symbols linked into \texttt{R}.

The additional arguments to \texttt{dyn.load} mirror the different aspects of the \texttt{mode} argument to the \texttt{dlopen()} routine on POSIX systems. They are available so that users can exercise greater control over the loading process for an individual library. In general, the default values are appropriate and you should override them only if there is good reason and you understand the implications.

The \texttt{local} argument allows one to control whether the symbols in the DLL being attached are visible to other DLLs. While maintaining the symbols in their own namespace is good practice, the ability to share symbols across related ‘chapters’ is useful in many cases. Additionally, on certain platforms and versions of an operating system, certain libraries must have their symbols loaded globally to successfully resolve all symbols.

One should be careful of the potential side-effect of using lazy loading via the \texttt{now} argument as \texttt{FALSE}. If a routine is called that has a missing symbol, the process will terminate immediately. The intended use is for library developers to call with value \texttt{TRUE} to check that all symbols are actually resolved and for regular users to call with \texttt{FALSE} so that missing symbols can be ignored and the available ones can be called.

The initial motivation for adding these was to avoid such termination in the \_init() routines of the Java virtual machine library. However, symbols loaded locally may not be (read probably) available to other DLLs. Those added to the global table are available to all other elements of the application and so can be shared across two different DLLs.

Some (very old) systems do not provide (explicit) support for local/global and lazy/eager symbol resolution. This can be the source of subtle bugs. One can arrange to have warning messages emitted when unsupported options are used. This is done by setting either of the options \texttt{verbose} or \texttt{warn} to be non-zero via the \texttt{options} function.

There is a short discussion of these additional arguments with some example code available at \url{http://www.stat.ucdavis.edu/~duncan/R/dynload/}.

**Value**

The function \texttt{dyn.load} is used for its side effect which links the specified DLL to the executing \texttt{R} image. Calls to \texttt{.C}, \texttt{.Call}, \texttt{.Fortran} and \texttt{.External} can then be used to execute compiled C functions or Fortran subroutines contained in the library. The return value of \texttt{dyn.load} is an object of class \texttt{DLLInfo}. See \texttt{getLoadedDLLs} for information about this class.

The function \texttt{dyn.unload} unlinks the DLL. Note that unloading a DLL and then re-loading a DLL of the same name may or may not work: on Solaris it uses the first version loaded.

\texttt{is.loaded} checks if the symbol name is loaded \textit{and searchable} and hence available for use as a character string value for argument \texttt{.NAME} in \texttt{.C} or \texttt{.Fortran} or \texttt{.Call} or \texttt{.External}. It will succeed if any one of the four calling functions would succeed in using the entry point unless \texttt{type} is specified. (See \texttt{.Fortran} for how Fortran symbols are mapped.) Note that symbols in base packages are not searchable, and other packages can be so marked.

**Warning**

Do not use \texttt{dyn.unload} on a DLL loaded by \texttt{library.dynam}: use \texttt{library.dynam.unload}. This is needed for system housekeeping.
Note

`is.loaded` requires the name you would give to `.C` etc and not (as in S) that remapped by the `defunct` functions `symbol.C` or `symbol.Fortran`.

By default, the maximum number of DLLs that can be loaded is now 614 when the OS limit on the number of open files allows or can be increased, but less otherwise. A specific maximum can be requested via the environment variable `R_MAX_NUM_DLLS`, which has to be set before starting an R session. If the OS limit on the number of open files does not allow using this maximum and cannot be increased, R will fail to start with an error. The maximum is not allowed to be greater than 60% of the OS limit on the number of open files (essentially unlimited on Windows, on Unix typically 1024, but 256 on macOS). The limit can sometimes be modified using command `ulimit -n (sh, bash) or limit descriptors (csh)` in the shell used to launch R. Increasing `R_MAX_NUM_DLLS` comes with some memory overhead.

The creation of DLLs and the runtime linking of them into executing programs is very platform dependent. In recent years there has been some simplification in the process because the C subroutine call `dlopen` has become the POSIX standard for doing this. Under Unix-alikes `dyn.load` uses the `dlopen` mechanism and should work on all platforms which support it. On Windows it uses the standard mechanism (LoadLibrary) for loading DLLs.

The original code for loading DLLs in Unix-alikes was provided by Heiner Schwarte.

is.loaded("supsmu", "stats", "Fortran")
is.loaded("PDF", type = "External") # pdf() device in grDevices
```

eapply

Apply a Function Over Values in an Environment

description

eapply applies FUN to the named values from an environment and returns the results as a list. The user can request that all named objects are used (normally names that begin with a dot are not). The output is not sorted and no enclosing environments are searched.

This is a primitive function.

Usage

eapply(env, FUN, ..., all.names = FALSE, USE.NAMES = TRUE)
eigen

Spectral Decomposition of a Matrix

Description

Computes eigenvalues and eigenvectors of numeric (double, integer, logical) or complex matrices.

Usage

eigen(x, symmetric, only.values = FALSE, EISPACK = FALSE)
Arguments

- `x`: a numeric or complex matrix whose spectral decomposition is to be computed. Logical matrices are coerced to numeric.
- `symmetric`: if TRUE, the matrix is assumed to be symmetric (or Hermitian if complex) and only its lower triangle (diagonal included) is used. If `symmetric` is not specified, `isSymmetric(x)` is used.
- `only.values`: if TRUE, only the eigenvalues are computed and returned, otherwise both eigenvalues and eigenvectors are returned.
- `EISPACK`: logical. Defunct and ignored.

Details

If `symmetric` is unspecified, `isSymmetric(x)` determines if the matrix is symmetric up to plausible numerical inaccuracies. It is surer and typically much faster to set the value yourself.

Computing the eigenvectors is the slow part for large matrices.

Computing the eigendecomposition of a matrix is subject to errors on a real-world computer: the definitive analysis is Wilkinson (1965). All you can hope for is a solution to a problem suitably close to `x`. So even though a real asymmetric `x` may have an algebraic solution with repeated real eigenvalues, the computed solution may be of a similar matrix with complex conjugate pairs of eigenvalues.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code (most often 1): these can only be interpreted by detailed study of the FORTRAN code.

Value

The spectral decomposition of `x` is returned as a list with components

- `values`: a vector containing the `p` eigenvalues of `x`, sorted in decreasing order, according to `Mod(values)` in the asymmetric case when they might be complex (even for real matrices). For real asymmetric matrices the vector will be complex only if complex conjugate pairs of eigenvalues are detected.
- `vectors`: either a `p` × `p` matrix whose columns contain the eigenvectors of `x`, or NULL if `only.values` is TRUE. The vectors are normalized to unit length.

Recall that the eigenvectors are only defined up to a constant; even when the length is specified they are still only defined up to a scalar of modulus one (the sign for real matrices).

When `only.values` is not true, as by default, the result is of S3 class "eigen".

If `r <- eigen(A)`, and `V <- r$vectors; lam <- r$values`, then

\[ A = V \Lambda V^{-1} \]

(up to numerical fuzz), where \( \Lambda = \text{diag(lam)} \).

Source

eigen uses the LAPACK routines DSYEVR, DGEEV, ZHEEV and ZGEEV.

LAPACK is from http://www.netlib.org/lapack and its guide is listed in the references.

encodeString

References
Brooks/Cole.
See Also
svd, a generalization of eigen; qr, and chol for related decompositions.
To compute the determinant of a matrix, the qr decomposition is much more efficient: det.
Examples
eigen(cbind(c(1,-1), c(-1,1)))
eigen(cbind(c(1,-1), c(-1,1)), symmetric = FALSE)
# same (different algorithm).
eigen(cbind(1, c(1,-1)), only.values = TRUE)
eigen(cbind(-1, 2:1)) # complex values
eigen(print(cbind(c(0, 1i), c(-1i, 0)))) # Hermite ==> real Eigenvalues
## 3 x 3:
eigen(cbind( 1, 3:1, 1:3))
eigen(cbind(-1, c(1:2,0), 0:2)) # complex values

encodeString

Encode Character Vector as for Printing

Description
encodeString escapes the strings in a character vector in the same way print.default does, and
optionally fits the encoded strings within a field width.
Usage
encodeString(x, width = 0, quote = "", na.encode = TRUE,
justify = c("left", "right", "centre", "none"))
Arguments
x

A character vector, or an object that can be coerced to one by as.character.

width

integer: the minimum field width. If NULL or NA, this is taken to be the largest
field width needed for any element of x.

quote

character: quoting character, if any.

na.encode

logical: should NA strings be encoded?

justify

character: partial matches are allowed. If padding to the minimum field width
is needed, how should spaces be inserted? justify == "none" is equivalent to
width = 0, for consistency with format.default.


Details

This escapes backslash and the control characters ‘\a’ (bell), ‘\b’ (backspace), ‘\f’ (formfeed), ‘\n’ (line feed), ‘\r’ (carriage return), ‘\t’ (tab) and ‘\v’ (vertical tab) as well as any non-printable characters in a single-byte locale, which are printed in octal notation (‘\xyz’ with leading zeroes).

Which characters are non-printable depends on the current locale. Windows’ reporting of printable characters is unreliable, so there all other control characters are regarded as non-printable, and all characters with codes 32–255 as printable in a single-byte locale. See print.default for how non-printable characters are handled in multi-byte locales.

If quote is a single or double quote any embedded quote of the same type is escaped. Note that justification is of the quoted string, hence spaces are added outside the quotes.

Value

A character vector of the same length as x, with the same attributes (including names and dimensions) but with no class set.

Marked UTF-8 encodings are preserved.

Note

The default for width is different from format.default, which does similar things for character vectors but without encoding using escapes.

See Also

print.default

Examples

```r
x <- "ab\bc\ndef"
print(x)
cat(x) # interprets escapes
cat(encodeString(x), "\n", sep = "") # similar to print()

factor(x) # makes use of this to print the levels

x <- c("a", "ab", "abcde")
encodeString(x) # width = 0: use as little as possible
encodeString(x, 2) # use two or more (left justified)
encodeString(x, width = NA) # left justification
encodeString(x, width = NA, justify = "c")
encodeString(x, width = NA, justify = "r")
encodeString(x, width = NA, quote = "", justify = "r")
```

---

**Encoding**  
Read or Set the Declared Encodings for a Character Vector

Description

Read or set the declared encodings for a character vector.
Usage

Encoding(x)

Encoding(x) <- value

enc2native(x)
enc2utf8(x)

Arguments

x  A character vector.

value  A character vector of positive length.

Details

Character strings in R can be declared to be encoded in "latin1" or "UTF-8" or as "bytes". These declarations can be read by Encoding, which will return a character vector of values "latin1", "UTF-8" "bytes" or "unknown", or set, when value is recycled as needed and other values are silently treated as "unknown". ASCII strings will never be marked with a declared encoding, since their representation is the same in all supported encodings. Strings marked as "bytes" are intended to be non-ASCII strings which should be manipulated as bytes, and never converted to a character encoding (so writing them to a text file is not supported).

denc2native and enc2utf8 convert elements of character vectors to the native encoding or UTF-8 respectively, taking any marked encoding into account. They are primitive functions, designed to do minimal copying.

There are other ways for character strings to acquire a declared encoding apart from explicitly setting it (and these have changed as R has evolved). Functions scan, read.table, readLines, and parse have an encoding argument that is used to declare encodings. iconv declares encodings from its to argument, and console input in suitable locales is also declared. intToUtf8 declares its output as "UTF-8", and output text connections (see textConnection) are marked if running in a suitable locale. Under some circumstances (see its help page) source(encoding=) will mark encodings of character strings it outputs.

Most character manipulation functions will set the encoding on output strings if it was declared on the corresponding input. These include chartr, strsplit(useBytes = FALSE), tolower and toupper as well as sub(useBytes = FALSE) and gsub(useBytes = FALSE). Note that such functions do not preserve the encoding, but if they know the input encoding and that the string has been successfully re-encoded (to the current encoding or UTF-8), they mark the output.

substr does preserve the encoding, and chartr, tolower and toupper preserve UTF-8 encoding on systems with Unicode wide characters. With their fixed and perl options, strsplit, sub and gsub will give a marked UTF-8 result if any of the inputs are UTF-8.

paste and sprintf return elements marked as bytes if any of the corresponding inputs is marked as bytes, and otherwise marked as UTF-8 of any of the inputs is marked as UTF-8.

match, pmatch, charmatch, duplicated and unique all match in UTF-8 if any of the elements are marked as UTF-8.

Value

A character vector.

For enc2utf8 encodings are always marked: they are for enc2native in UTF-8 and Latin-1 locales.
Examples

```r
## x is intended to be in latin1
x <- "fa\xE7ile"
Encoding(x)
Encoding(x) <- "latin1"
x
xx <- iconv(x, "latin1", "UTF-8")
Encoding(c(x, xx))
c(x, xx)
Encoding(xx) <- "bytes"
x
xx # will be encoded in hex
cat("xx = ", xx, "\n", sep = "")
```

environment

### Environment Access

#### Description

Get, set, test for and create environments.

#### Usage

```r
environment(fun = NULL)
environment(fun) <- value

is.environment(x)

.baseenv()
.globalenv()

emptyenv()
.baseenv()

new.env(hash = TRUE, parent = parent.frame(), size = 29L)

parent.env(env)
parent.env(env) <- value

environmentName(env)

env.profile(env)
```

#### Arguments

- **fun**: a function, a formula, or NULL, which is the default.
- **value**: an environment to associate with the function
- **x**: an arbitrary R object.
- **hash**: a logical, if TRUE the environment will use a hash table.
- **parent**: an environment to be used as the enclosure of the environment created.
**Details**

Environments consist of a *frame*, or collection of named objects, and a pointer to an *enclosing environment*. The most common example is the frame of variables local to a function call; its *enclosure* is the environment where the function was defined (unless changed subsequently). The enclosing environment is distinguished from the *parent frame*: the latter (returned by `parent.frame`) refers to the environment of the caller of a function. Since confusion is so easy, it is best never to use 'parent' in connection with an environment (despite the presence of the function `parent.env`).

When `get` or `exists` search an environment with the default `inherits = TRUE`, they look for the variable in the frame, then in the enclosing frame, and so on.

The global environment `.GlobalEnv`, more often known as the user’s workspace, is the first item on the search path. It can also be accessed by `globalenv()`. On the search path, each item’s enclosure is the next item.

The object `.BaseNamespaceEnv` is the namespace environment for the base package. The environment of the base package itself is available as `baseenv()`.

If one follows the chain of enclosures found by repeatedly calling `parent.env` from any environment, eventually one reaches the empty environment `emptyenv()`, into which nothing may be assigned.

The replacement function `parent.env<-` is extremely dangerous as it can be used to destructively change environments in ways that violate assumptions made by the internal C code. It may be removed in the near future.

The replacement form of `environment`, `is.environment`, `baseenv`, `emptyenv` and `globalenv` are *primitive* functions.

System environments, such as the base, global and empty environments, have names as do the package and namespace environments and those generated by `attach()`. Other environments can be named by giving a "name" attribute, but this needs to be done with care as environments have unusual copying semantics.

**Value**

If `fun` is a function or a formula then `environment(fun)` returns the environment associated with that function or formula. If `fun` is `NULL` then the current evaluation environment is returned.

The replacement form sets the environment of the function or formula `fun` to the value given.

- `is.environment(obj)` returns `TRUE` if and only if `obj` is an environment.
- `new.env` returns a new (empty) environment with (by default) enclosure the parent frame.
- `parent.env` returns the enclosing environment of its argument.
- `parent.env<-` sets the enclosing environment of its first argument.
- `environmentName` returns a character string, that given when the environment is printed or "" if it is not a named environment.

`env.profile` returns a list with the following components: `size` the number of chains that can be stored in the hash table, `nchains` the number of non-empty chains in the table (as reported by `HASHPRI`), and `counts` an integer vector giving the length of each chain (zero for empty chains). This function is intended to assess the performance of hashed environments. When `env` is a nonhashed environment, `NULL` is returned.
See Also

For the performance implications of hashing or not, see https://en.wikipedia.org/wiki/Hash_table.

The `envir` argument of `eval`, `get`, and `exists`. 

`ls` may be used to view the objects in an environment, and hence `ls.str` may be useful for an overview.

`sys.source` can be used to populate an environment.

Examples

```r
f <- function() "top level function"

###-- all three give the same:
environment()
environment(f)
_.GlobalEnv

ls(envir = environment(stats::approxfun(1:2, 1:2, method = "const")))

is.environment(_.GlobalEnv) # TRUE

e1 <- new.env(parent = baseenv()) # this one has enclosure package:base.
e2 <- new.env(parent = e1)
assign("a", 3, envir = e1)
ls(e1)
ls(e2)
exists("a", envir = e2) # this succeeds by inheritance
exists("a", envir = e2, inherits = FALSE)
exists("+", envir = e2) # this succeeds by inheritance

eh <- new.env(hash = TRUE, size = NA)
with(env.profile(eh), stopifnot(size == length(counts)))
```

---

### EnvVar

**Environment Variables**

<table>
<thead>
<tr>
<th>Description</th>
<th>Details</th>
</tr>
</thead>
</table>
| Details     | It is impossible to list all the environment variables which can affect an R session: some affect the OS system functions which R uses, and others will affect add-on packages. But here are notes on some of the more important ones. Those that set the defaults for options are consulted only at startup (as are some of the others).
| HOME:       | The user’s ‘home’ directory. |
| LANGUAGE:   | Optional. The language(s) to be used for message translations. This is consulted when needed. |
| LC_ALL:     | (etc) Optional. Use to set various aspects of the locale – see Sys.getlocale. Consulted at startup. |
MAKINDEX: The path to makeindex. If unset to a value determined when R was built. Used by the emulation mode of texi2dvi and texi2pdf.

R_BATCH: Optional – set in a batch session, that is one started by R CMD BATCH. Most often set to ",", so test by something like !is.na(Sys.getenv("R_BATCH", NA)).

R_BROWSER: The path to the default browser. Used to set the default value of options("browser").

R_COMPLETION: Optional. If set to FALSE, command-line completion is not used. (Not used by the macOS GUI.)

R_DEFAULT_PACKAGES: A comma-separated list of packages which are to be attached in every session. See options.

R_DOC_DIR: The location of the R 'doc' directory. Set by R.

R_ENVIRON: Optional. The path to the site environment file: see Startup. Consulted at startup.

R_GSCMD: Optional. The path to Ghostscript, used by dev2bitmap, bitmap and embedFonts. Consulted when those functions are invoked. Since it will be treated as if passed to system, spaces and shell metacharacters should be escaped.

R_HISTORYFILE: Optional. The path of the history file: see Startup. Consulted at startup and when the history is saved.

R_HISTSIZE: Optional. The maximum size of the history file, in lines. Exactly how this is used depends on the interface. For the readline command-line interface it takes effect when the history is saved (by savehistory or at the end of a session).

R_HOME: The top-level directory of the R installation: see R.home. Set by R.

R_INCLUDE_DIR: The location of the R ‘include’ directory. Set by R.

R_LIBS: Optional. Used for initial setting of .libPaths.

R_LIBS_SITE: Optional. Used for initial setting of .libPaths.

R_LIBS_USER: Optional. Used for initial setting of .libPaths.

R_PAPERSIZE: Optional. Used to set the default for options("papersize"), e.g. used by pdf and postscript.

R_PCRE_JIT_STACK_MAXSIZE: Optional. Consulted when PCRE's JIT pattern compiler is first used. See grep.

R_PDFVIEWER: The path to the default PDF viewer. Used by R CMD Rd2pdf.

R_PLATFORM: The platform – a string of the form cpu-vendor-os, see R.Version.

R_PROFILE: Optional. The path to the site profile file: see Startup. Consulted at startup.

R_RDWRPDF: Options for pdflatex processing of Rd files. Used by R CMD Rd2pdf.

R_SHARE_DIR: The location of the R 'share' directory. Set by R.

R_TEXI2DVICMD: The path to texi2dvi. Defaults to the value of TEXI2DVI, and if that is unset to a value determined when R was built. Consulted at startup to set the default for options("texi2dvi"), used by texi2dvi and texi2pdf in package tools.

R_UNZIPCMD: The path to unzip. Sets the initial value for options("unzip") on a Unix-alike when namespace utils is loaded.

R_ZIPCMD: The path to zip. Used by zip and by R CMD INSTALL --build on Windows.

TMPDIR, TMP, TEMP: Consulted (in that order) when setting the temporary directory for the session: see tmpdir. TMPDIR is also used by some of the utilities see the help for build.

TZ: Optional. The current time zone. See Sys.timezone for the system-specific formats. Consulted as needed.

no_proxy, http_proxy, ftp_proxy: (and more). Optional. Settings for download.file: see its help for further details.
Unix-specific

Some variables set on Unix-alikes, and not (in general) on Windows.

DISPLAY: Optional: used by X1, Tk (in package tcltk), the data editor and various packages.

EDITOR: The path to the default editor: sets the default for options("editor") when namespace utils is loaded.

PAGER: The path to the pager with the default setting of options("pager"). The default value is chosen at configuration, usually as the path to less.

R_PRINTCMD: Sets the default for options("printcmd"), which sets the default print command to be used by postscript.

Sys.getenv and Sys.setenv to read and set environmental variables in an R session.
gctorture for environment variables controlling garbage collection.

eval

Evaluate an (Unevaluated) Expression

description

Evaluate an R expression in a specified environment.

Usage

eval(expr, envir = parent.frame(),
  enclos = if(is.list(envir) || is.pairlist(envir))
    parent.frame() else baseenv())
evalq(expr, envir, enclos)
eval.parent(expr, n = 1)
local(expr, envir = new.env())

Arguments

expr an object to be evaluated. See ‘Details’.
envir the environment in which expr is to be evaluated. May also be NULL, a list, a data frame, a pairlist or an integer as specified to sys.call.
enclos Relevant when envir is a (pair)list or a data frame. Specifies the enclosure, i.e., where R looks for objects not found in envir. This can be NULL (interpreted as the base package environment, baseenv()) or an environment.
n number of parent generations to go back
Details

eval evaluates the expr argument in the environment specified by envir and returns the computed value. If envir is not specified, then the default is parent.frame() (the environment where the call to eval was made).

Objects to be evaluated can be of types call or expression or name (when the name is looked up in the current scope and its binding is evaluated), a promise or any of the basic types such as vectors, functions and environments (which are returned unchanged).

The evalq form is equivalent to eval(quote(expr), ...). eval evaluates its first argument in the current scope before passing it to the evaluator: evalq avoids this.

eval.parent(expr, n) is a shorthand for eval(expr, parent.frame(n)).

If envir is a list (such as a data frame) or pairlist, it is copied into a temporary environment (with enclosure enclos), and the temporary environment is used for evaluation. So if expr changes any of the components named in the (pair)list, the changes are lost.

If envir is NULL it is interpreted as an empty list so no values could be found in envir and look-up goes directly to enclos.

local evaluates an expression in a local environment. It is equivalent to evalq except that its default argument creates a new, empty environment. This is useful to create anonymous recursive functions and as a kind of limited namespace feature since variables defined in the environment are not visible from the outside.

Value

The result of evaluating the object: for an expression vector this is the result of evaluating the last element.

Note

Due to the difference in scoping rules, there are some differences between R and S in this area. In particular, the default enclosure in S is the global environment.

When evaluating expressions in a data frame that has been passed as an argument to a function, the relevant enclosure is often the caller's environment, i.e., one needs eval(x, data, parent.frame()).

References

See Also

expression, quote, sys.frame, parent.frame, environment.

Further, force to force evaluation, typically of function arguments.

Examples

eval(2 ^ 2 ^ 3)
mEx <- expression(2^2^3); mEx; 1 + eval(mEx)
eval({ xx <- pi; xx^2}) ; xx
a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, list(a = 1)), list(b = 5)) # == 10
a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, -1), list(b = 5)) # == 12
eval

```r
ev <- function() {
e1 <- parent.frame()
## Evaluate a in e1
aa <- eval(expression(a), e1)
## evaluate the expression bound to a in e1
a <- expression(x+y)
list(aa = aa, eval = eval(a, e1))
}
tst.ev <- function(a = 7) { x <- pi; y <- 1; ev() }
tst.ev() #-> aa : 7, eval : 4.14

a <- list(a = 3, b = 4)
with(a, a <- 5) # alters the copy of a from the list, discarded.

##
## Example of evalq()
##
N <- 3
e1 <- new.env()
assign("N", 27, envir = env)
## this version changes the visible copy of N only, since the argument
## passed to eval is '4'.
eval(N <- 4, env)
N
get("N", envir = env)
## this version does the assignment in env, and changes N only there.
evalq(N <- 5, env)
N
get("N", envir = env)

##
## Uses of local()
##
# Mutually recursive.
# gg gets value of last assignment, an anonymous version of f.

gg <- local({
k <- function(y)f(y)
  f <- function(x) if(x) x*k(x-1) else 1
})
gg(10)
sapply(1:5, gg)

# Nesting locals: a is private storage accessible to k
gg <- local({
k <- local({
  a <- 1
  function(y){print(a <<- a+1);f(y)}
})
  f <- function(x) x*k(x-1) else 1
})
sapply(1:5, gg)
```

exists

Is an Object Defined?

Description

Look for an R object of the given name and possibly return it.

Usage

exists(x, where = -1, envir = , frame, mode = "any", inherits = TRUE)

get0(x, envir = pos.to.env(-1L), mode = "any", inherits = TRUE, ifnotfound = NULL)

Arguments

x a variable name (given as a character string).
where where to look for the object (see the details section); if omitted, the function will search as if the name of the object appeared unquoted in an expression.
envir an alternative way to specify an environment to look in, but it is usually simpler to just use the where argument.
frame a frame in the calling list. Equivalent to giving where as sys.frame(frame).
mode the mode or type of object sought: see the ‘Details’ section.
inherits should the enclosing frames of the environment be searched?
ifnotfound the return value of get0(x, *) when x does not exist.

Details

The where argument can specify the environment in which to look for the object in any of several ways: as an integer (the position in the search list); as the character string name of an element in the search list; or as an environment (including using sys.frame to access the currently active function calls). The envir argument is an alternative way to specify an environment, but is primarily there for back compatibility.

This function looks to see if the name x has a value bound to it in the specified environment. If inherits is TRUE and a value is not found for x in the specified environment, the enclosing frames of the environment are searched until the name x is encountered. See environment and the ‘R Language Definition’ manual for details about the structure of environments and their enclosures.

Warning: inherits = TRUE is the default behaviour for R but not for S.

If mode is specified then only objects of that type are sought. The mode may specify one of the collections "numeric" and "function" (see mode): any member of the collection will suffice. (This is true even if a member of a collection is specified, so for example mode = "special" will seek any type of function.)
Value

exists(): Logical, true if and only if an object of the correct name and mode is found.
get0(): The object—as from get(x, *)—if exists(x, *) is true, otherwise ifnotfound.

Note

With get0(), instead of the easy to read but somewhat inefficient

```r
if (exists(myVarName, envir = myEnvir)) {
  r <- get(myVarName, envir = myEnvir)
  ## ... deal with r ... 
}
```

you now can use the more efficient (and slightly harder to read)

```r
if (!is.null(r <- get0(myVarName, envir = myEnvir))) {
  ## ... deal with r ... 
}
```

References

See Also

get and hasName. For quite a different kind of “existence” checking, namely if function arguments were specified, missing; and for yet a different kind, namely if a file exists, file.exists.

Examples

```r
## Define a substitute function if necessary:
if(!exists("some.fun", mode = "function"))
  some.fun <- function(x) { cat("some.fun(x)\n"); x }
search()
exists("ls", 2) # true even though ls is in pos = 3
exists("ls", 2, inherits = FALSE) # false

## These are true (in most circumstances):
identical(ls, get0("ls"))
identical(NULL, get0(".foo.bar.")) # default ifnotfound = NULL (!)
```

---

**expand.grid**

Create a Data Frame from All Combinations of Factor Variables

Description

Create a data frame from all combinations of the supplied vectors or factors. See the description of the return value for precise details of the way this is done.
Usage

expand.grid(..., KEEP.OUT.ATTRS = TRUE, stringsAsFactors = TRUE)

Arguments

... vectors, factors or a list containing these.
KEEP.OUT.ATTRS a logical indicating the "out.attrs" attribute (see below) should be computed
and returned.
stringsAsFactors logical specifying if character vectors are converted to factors.

Value

A data frame containing one row for each combination of the supplied factors. The first factors vary
fastest. The columns are labelled by the factors if these are supplied as named arguments or named
components of a list. The row names are 'automatic'.

Attribute "out.attrs" is a list which gives the dimension and dimnames for use by predict meth-
ods.

Note

Conversion to a factor is done with levels in the order they occur in the character vectors (and not
alphabetically, as is most common when converting to factors).

References

See Also

combn (package utils) for the generation of all combinations of n elements, taken m at a time.

Examples

require(utils)
expand.grid(height = seq(60, 80, 5), weight = seq(100, 300, 50),
  sex = c("Male", "Female"))

x <- seq(0, 10, length.out = 100)
y <- seq(-1, 1, length.out = 20)
d1 <- expand.grid(x = x, y = y)
d2 <- expand.grid(x = x, y = y, KEEP.OUT.ATTRS = FALSE)
object.size(d1) - object.size(d2)
##-> 5992 or 8832 (on 32- / 64-bit platform)
expression

Unevaluated Expressions

Description

Creates or tests for objects of mode "expression".

Usage

expression(...)

is.expression(x)
as.expression(x, ...)

Arguments

...  expression: R objects, typically calls, symbols or constants.
as.expression: arguments to be passed to methods.
x  an arbitrary R object.

Details

‘Expression’ here is not being used in its colloquial sense, that of mathematical expressions. Those are calls (see call) in R, and an R expression vector is a list of calls, symbols etc, for example as returned by parse.

As an object of mode "expression" is a list, it can be subsetted by [, [, or $, the latter two extracting individual calls etc. The replacement forms of these operators can be used to replace or delete elements.

expression and is.expression are primitive functions. expression is 'special': it does not evaluate its arguments.

Value

expression returns a vector of type "expression" containing its arguments (unevaluated).
is.expression returns TRUE if expr is an expression object and FALSE otherwise.
as.expression attempts to coerce its argument into an expression object. It is generic, and only the default method is described here. (The default method calls as.vector(type = "expression") and so may dispatch methods for as.vector.) NULL, calls, symbols (see as.symbol) and pairlists are returned as the element of a length-one expression vector. Atomic vectors are placed element-by-element into an expression vector (without using any names): lists are changed type to an expression vector (keeping all attributes). Other types are not currently supported.

References

See Also

call, eval, function. Further, text and legend for plotting mathematical expressions.
Examples

```
length(ex1 <- expression(1 + 0:9)) # 1
ex1
eval(ex1) # 1:10
length(ex3 <- expression(u, v, 1+0:9)) # 3
mode(ex3[3]) # expression
mode(ex3[[3]]) # call
rm(ex3)
```

Extract or Replace Parts of an Object

Description

Operators acting on vectors, matrices, arrays and lists to extract or replace parts.

Usage

```
x[i]
x[i, j, ... , drop = TRUE]
x[[i, exact = TRUE]]
x[[i, j, ... , exact = TRUE]]
x$name
getElement(object, name)
```

```
x[i] <- value
x[i, j, ...] <- value
x[[i]] <- value
x$name <- value
```

Arguments

- `x, object` object from which to extract element(s) or in which to replace element(s).
- `i, j, ...` indices specifying elements to extract or replace. Indices are numeric or character vectors or empty (missing) or NULL. Numeric values are coerced to integer as by `as.integer` (and hence truncated towards zero). Character vectors will be matched to the names of the object (or for matrices/arrays, the `dimnames`): see ‘Character indices’ below for further details.
  For `[.-indexing only: `i, j, ...` can be logical vectors, indicating elements/slices to select. Such vectors are recycled if necessary to match the corresponding extent. `i, j, ...` can also be negative integers, indicating elements/slices to leave out of the selection.
  When indexing arrays by `[ a single argument `i` can be a matrix with as many columns as there are dimensions of `x`; the result is then a vector with elements corresponding to the sets of indices in each row of `i`.
  An index value of NULL is treated as if it were `integer(0)`.
- `name` A literal character string or a name (possibly backtick quoted). For extraction, this is normally (see under ‘Environments’) partially matched to the names of the object.
drop

For matrices and arrays. If TRUE the result is coerced to the lowest possible dimension (see the examples). This only works for extracting elements, not for the replacement. See drop for further details.

exact

Controls possible partial matching of [[] when extracting by a character vector (for most objects, but see under 'Environments'). The default is no partial matching. Value NA allows partial matching but issues a warning when it occurs. Value FALSE allows partial matching without any warning.

value

typically an array-like R object of a similar class as x.

Details

These operators are generic. You can write methods to handle indexing of specific classes of objects, see InternalMethods as well as [.data.frame and [.factor. The descriptions here apply only to the default methods. Note that separate methods are required for the replacement functions [<-, [[<- and $<- for use when indexing occurs on the assignment side of an expression.

The most important distinction between [], [[ and $ is that the [] can select more than one element whereas the other two select a single element.

The default methods work somewhat differently for atomic vectors, matrices/arrays and for recursive (list-like, see is.recursive) objects. $ is only valid for recursive objects, and is only discussed in the section below on recursive objects.

Subsetting (except by an empty index) will drop all attributes except names, dim and dimnames.

Indexing can occur on the right-hand-side of an expression for extraction, or on the left-hand-side for replacement. When an index expression appears on the left side of an assignment (known as subassignment) then that part of x is set to the value of the right hand side of the assignment. In this case no partial matching of character indices is done, and the left-hand-side is coerced as needed to accept the values. For vectors, the answer will be of the higher of the types of x and value in the hierarchy raw < logical < integer < double < complex < character < list < expression. Attributes are preserved (although names, dim and dimnames will be adjusted suitably). Subassignment is done sequentially, so if an index is specified more than once the latest assigned value for an index will result.

It is an error to apply any of these operators to an object which is not subsettable (e.g., a function).

Atomic vectors

The usual form of indexing is [. [[] can be used to select a single element dropping names, whereas [ keeps them, e.g., in c(abc = 123)[1].

The index object i can be numeric, logical, character or empty. Indexing by factors is allowed and is equivalent to indexing by the numeric codes (see factor) and not by the character values which are printed (for which use [as.character(i)]).

An empty index selects all values: this is most often used to replace all the entries but keep the attributes.

Matrices and arrays

Matrices and arrays are vectors with a dimension attribute and so all the vector forms of indexing can be used with a single index. The result will be an unnamed vector unless x is one-dimensional when it will be a one-dimensional array.

The most common form of indexing a k-dimensional array is to specify k indices to [. As for vector indexing, the indices can be numeric, logical, character, empty or even factor. An empty index (a
comma separated blank) indicates that all entries in that dimension are selected. The argument drop applies to this form of indexing.

A third form of indexing is via a numeric matrix with the one column for each dimension: each row of the index matrix then selects a single element of the array, and the result is a vector. Negative indices are not allowed in the index matrix. NA and zero values are allowed: rows of an index matrix containing a zero are ignored, whereas rows containing an NA produce an NA in the result.

Indexing via a character matrix with one column per dimensions is also supported if the array has dimension names. As with numeric matrix indexing, each row of the index matrix selects a single element of the array. Indices are matched against the appropriate dimension names. NA is allowed and will produce an NA in the result. Unmatched indices as well as the empty string (""") are not allowed and will result in an error.

A vector obtained by matrix indexing will be unnamed unless x is one-dimensional when the row names (if any) will be indexed to provide names for the result.

**Recursive (list-like) objects**

Indexing by [ is similar to atomic vectors and selects a list of the specified element(s).

Both [[ and $ select a single element of the list. The main difference is that $ does not allow computed indices, whereas [[ does. x$name is equivalent to x[["name", exact = FALSE]]. Also, the partial matching behavior of [[ can be controlled using the exact argument.

getElement(x, name) is a version of x[[name, exact = TRUE]] which for formally classed (S4) objects returns slot(x, name), hence providing access to even more general list-like objects.

[ and [[ are sometimes applied to other recursive objects such as calls and expressions. Pairlists are coerced to lists for extraction by [], but all three operators can be used for replacement.

[[ can be applied recursively to lists, so that if the single index i is a vector of length p, alist[[i]] is equivalent to alist[[i1]]...[[ip]] providing all but the final indexing results in a list. Note that in all three kinds of replacement, a value of NULL deletes the corresponding item of the list. To set entries to NULL, you need x[i] <- list(NULL).

When $<- is applied to a NULL x, it first coerces x to list(). This is what also happens with [[<- if the replacement value value is of length greater than one: if value has length 1 or 0, x is first coerced to a zero-length vector of the type of value.

**Environments**

Both $ and [[ can be applied to environments. Only character indices are allowed and no partial matching is done. The semantics of these operations are those of get(i, env = x, inherits = FALSE). If no match is found then NULL is returned. The replacement versions, $<- and [[<-, can also be used. Again, only character arguments are allowed. The semantics in this case are those of assign(i, value, env = x, inherits = FALSE). Such an assignment will either create a new binding or change the existing binding in x.

**NAs in indexing**

When extracting, a numerical, logical or character NA index picks an unknown element and so returns NA in the corresponding element of a logical, integer, numeric, complex or character result, and NULL for a list. (It returns ø for a raw result.)

When replacing (that is using indexing on the lhs of an assignment) NA does not select any element to be replaced. As there is ambiguity as to whether an element of the rhs should be used or not, this is only allowed if the rhs value is of length one (so the two interpretations would have the same outcome). (The documented behaviour of S was that an NA replacement index ‘goes nowhere’
but uses up an element of value: Becker et al p. 359. However, that has not been true of other implementations.

Argument matching

Note that these operations do not match their index arguments in the standard way: argument names are ignored and positional matching only is used. So m[j = 2, i = 1] is equivalent to m[2, 1] and not to m[1, 2].

This may not be true for methods defined for them; for example it is not true for the data.frame methods described in [.data.frame which warn if i or j is named and have undocumented behaviour in that case.

To avoid confusion, do not name index arguments (but drop and exact must be named).

S4 methods

These operators are also implicit S4 generics, but as primitives, S4 methods will be dispatched only on S4 objects x.

The implicit generics for the $ and $<- operators do not have name in their signature because the grammar only allows symbols or string constants for the name argument.

Character indices

Character indices can in some circumstances be partially matched (see pmatch) to the names or dimnames of the object being subsetted (but never for subassignment). Unlike S (Becker et al p. 358), R never uses partial matching when extracting by [, and partial matching is not by default used by [[ (see argument exact).

Thus the default behaviour is to use partial matching only when extracting from recursive objects (except environments) by $. Even in that case, warnings can be switched on by options(warnPartialMatchDollar = TRUE).

Neither empty (""") nor NA indices match any names, not even empty nor missing names. If any object has no names or appropriate dimnames, they are taken as all "" and so match nothing.

[, data.frame and [.factor for the behaviour when applied to data.frame and factors.

Syntax for operator precedence, and the ‘R Language Definition’ manual about indexing details.

NULL for details of indexing null objects.

Examples

x <- 1:12
m <- matrix(1:6, nrow = 2, dimnames = list(c("a", "b"), LETTERS[1:3]))
li <- list(pi = pi, e = exp(1))
x[10]    # the tenth element of x
Extract.data.frame

Extract or Replace Parts of a Data Frame

Description

Extract or replace subsets of data frames.
Usage

```r
## S3 method for class 'data.frame'
x[i, j, drop = ]
## S3 replacement method for class 'data.frame'
x[i, j] <- value
## S3 method for class 'data.frame'
x[[..., exact = TRUE]]
## S3 replacement method for class 'data.frame'
x[[i, j]] <- value
## S3 method for class 'data.frame'
x$name
## S3 replacement method for class 'data.frame'
x$name <- value
```

Arguments

- `x` data frame.
- `i, j, ...` elements to extract or replace. For `[` and `[[`, these are numeric or character or, for `[` only, empty. Numeric values are coerced to integer as if by `as.integer`. For replacement by `[`, a logical matrix is allowed.
- `name` A literal character string or a name (possibly backtick quoted).
- `drop` logical. If `TRUE` the result is coerced to the lowest possible dimension. The default is to drop if only one column is left, but not to drop if only one row is left.
- `value` A suitable replacement value: it will be repeated a whole number of times if necessary and it may be coerced: see the Coercion section. If `NULL`, deletes the column if a single column is selected.
- `exact` logical: see `[`, and applies to column names.

Details

Data frames can be indexed in several modes. When `[` and `[[` are used with a single vector index (`x[i]` or `x[[i]]`), they index the data frame as if it were a list. In this usage a drop argument is ignored, with a warning.

The `data.frame` method for `$`, treats x as a list, except that (as of R-3.1.0) partial matching of name to the names of x will generate a warning; this may become an error in future versions. The replacement method checks `value` for the correct number of rows, and replicates it if necessary.

When `[` and `[[` are used with two indices (`x[i, j]` and `x[[i, j]]`) they act like indexing a matrix: `[` can only be used to select one element. Note that for each selected column, `xj` say, typically (if it is not matrix-like), the resulting column will be `xj[i]`, and hence rely on the corresponding `[` method, see the examples section.

If `[` returns a data frame it will have unique (and non-missing) row names, if necessary transforming the row names using `make.unique`. Similarly, if columns are selected column names will be transformed to be unique if necessary (e.g., if columns are selected more than once, or if more than one column of a given name is selected if the data frame has duplicate column names).

When `drop = TRUE`, this is applied to the subsetting of any matrices contained in the data frame as well as to the data frame itself.

The replacement methods can be used to add whole column(s) by specifying non-existent column(s), in which case the column(s) are added at the right-hand edge of the data frame and numerical indices must be contiguous to existing indices. On the other hand, rows can be added at any
row after the current last row, and the columns will be in-filled with missing values. Missing values in the indices are not allowed for replacement.

For \([\) the replacement value can be a list: each element of the list is used to replace (part of) one column, recycling the list as necessary. If columns specified by number are created, the names (if any) of the corresponding list elements are used to name the columns. If the replacement is not selecting rows, list values can contain NULL elements which will cause the corresponding columns to be deleted. (See the Examples.)

Matrix indexing (\(x[i]\) with a logical or a 2-column integer matrix \(i\)) using \([\) is not recommended. For extraction, \(x\) is first coerced to a matrix. For replacement, logical matrix indices must be of the same dimension as \(x\). Replacements are done one column at a time, with multiple type coercions possibly taking place.

Both \([\) and \([[]\) extraction methods partially match row names. By default neither partially match column names, but \([\) will if exact = FALSE (and with a warning if exact = NA). If you want to exact matching on row names use \(match\), as in the examples.

**Value**

For \([\) a data frame, list or a single column (the latter two only when dimensions have been dropped). If matrix indexing is used for extraction a vector results. If the result would be a data frame an error results if undefined columns are selected (as there is no general concept of a 'missing' column in a data frame). Otherwise if a single column is selected and this is undefined the result is NULL.

For \([[]\) a column of the data frame or NULL (extraction with one index) or a length-one vector (extraction with two indices).

For \$, a column of the data frame (or NULL).

For \([\leftarrow\), \([[]\leftarrow\) and \$\leftarrow\), a data frame.

**Coercion**

The story over when replacement values are coerced is a complicated one, and one that has changed during \(R\)'s development. This section is a guide only.

When \([\) and \([[]\) are used to add or replace a whole column, no coercion takes place but value will be replicated (by calling the generic function \(rep\)) to the right length if an exact number of repeats can be used.

When \(\) is used with a logical matrix, each value is coerced to the type of the column into which it is to be placed.

When \(\) and \([[]\) are used with two indices, the column will be coerced as necessary to accommodate the value.

Note that when the replacement value is an array (including a matrix) it is not treated as a series of columns (as \(data.frame\) and \(as.data.frame\) do) but inserted as a single column.

**Warning**

The default behaviour when only one row is left is equivalent to specifying drop = FALSE. To drop from a data frame to a list, drop = TRUE has to be specified explicitly.

Arguments other than drop and exact should not be named: there is a warning if they are and the behaviour differs from the description here.

**See Also**

\(subset\) which is often easier for extraction, \(data.frame\), Extract.
Examples

sw <- swiss[1:5, 1:4]  # select a manageable subset

sw[1:3]  # select columns
sw[, 1:3]  # same
sw[4:5, 1:3]  # select rows and columns
sw[1]  # a one-column data frame
sw[, 1]  # a (unnamed) vector
sw[[1]]  # the same

sw[1,]  # a one-row data frame
sw[1,, drop = FALSE]  # a list

sw["C", ]  # partially matches
sw[match("C", row.names(sw)), ]  # no exact match
try(sw[, "Ferti"])  # column names must match exactly

swiss[ c(1, 1:2), ]  # duplicate row, unique row names are created

sw[sw <= 6] <- 6  # logical matrix indexing
sw

## adding a column
sw["new1"] <- LETTERS[1:5]  # adds a character column
sw[["new2"]] <- letters[1:5]  # ditto
sw[, "new3"] <- LETTERS[1:5]  # ditto
sw$new4 <- 1:5
sapply(sw, class)
sw$new4 <- NULL  # delete the column
sw

sw[6:8] <- list(letters[10:14], NULL, aa = 1:5)
# update col. 6, delete 7, append
sw

## matrices in a data frame
A <- data.frame(x = 1:3, y = I(matrix(4:9, 3, 2)),
                z = I(matrix(letters[1:9], 3, 3)))
A[1:3, "y"]  # a matrix
A[1:3, "z"]  # a matrix
A[,"y"]  # a matrix
stopifnot(identical(colnames(A), c("x", "y", "z")), ncol(A) == 3L,
          identical(A[,"y"], A[1:3, "y"]),
          inherits (A[,"y"], "AsIs"))

## keeping special attributes: use a class with a
## "as.data.frame" and "[" method;
## "avector" := vector that keeps attributes. Could provide a constructor
## avector <- function(x) { class(x) <- c("avector", class(x)); x }
as.data.frame.avector <- as.data.frame.vector

\`[.avector` <- function(x,i,...) {
  r <- NextMethod("[")
  mostattributes(r) <- attributes(x)
  r
d <- data.frame(i = 0:7, f = gl(2,4),
    u = structure(11:18, unit = "kg", class = "avector"))
str(d[2:4, -1]) # 'u' keeps its "unit"

---

**Extract.factor**

**Extract or Replace Parts of a Factor**

**Description**

Extract or replace subsets of factors.

**Usage**

```r
## S3 method for class 'factor'
x[...], drop = FALSE]
## S3 method for class 'factor'
x[[...]]
## S3 replacement method for class 'factor'
x[[...]] <- value
## S3 replacement method for class 'factor'
x[[...]] <- value
```

**Arguments**

- `x`: a factor
- `...`: a specification of indices – see `Extract`.
- `drop`: logical. If true, unused levels are dropped.
- `value`: character: a set of levels. Factor values are coerced to character.

**Details**

When unused levels are dropped the ordering of the remaining levels is preserved.

If `value` is not in `levels(x)`, a missing value is assigned with a warning.

Any `contrasts` assigned to the factor are preserved unless `drop = TRUE`.

The `[[]` method supports argument `exact`.

**Value**

A factor with the same set of levels as `x` unless `drop = TRUE`.

**See Also**

- `factor`, `Extract`

**Examples**

```r
## following example(factor)
(ff <- factor(substring("statistics", 1:10, 1:10), levels = letters))
ff[, drop = TRUE]
factor(letters[7:10])[2:3, drop = TRUE]
```
Description

Returns the (regular or parallel) maxima and minima of the input values.

`pmax*()` and `pmin*()` take one or more vectors as arguments, recycle them to common length and return a single vector giving the ‘parallel’ maxima (or minima) of the argument vectors.

Usage

```r
max(..., na.rm = FALSE)
min(..., na.rm = FALSE)
pmax(..., na.rm = FALSE)
pmin(..., na.rm = FALSE)
pmax.int(..., na.rm = FALSE)
pmin.int(..., na.rm = FALSE)
```

Arguments

- `...` numeric or character arguments (see Note).
- `na.rm` a logical indicating whether missing values should be removed.

Details

`max` and `min` return the maximum or minimum of all the values present in their arguments, as `integer` if all are logical or integer, as `double` if all are numeric, and character otherwise.

If `na.rm` is `FALSE` an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

The minimum and maximum of a numeric empty set are `+Inf` and `-Inf` (in this order!) which ensures transitivity, e.g., `min(x1, min(x2)) == min(x1, x2)`. For numeric `x max(x) == -Inf` and `min(x) == +Inf` whenever `length(x) == 0` (after removing missing values if requested). However, `pmax` and `pmin` return NA if all the parallel elements are NA even for `na.rm = TRUE`.

`pmax` and `pmin` take one or more vectors (or matrices) as arguments and return a single vector giving the ‘parallel’ maxima (or minima) of the vectors. The first element of the result is the maximum (minimum) of the first elements of all the arguments, the second element of the result is the maximum (minimum) of the second elements of all the arguments and so on. Shorter inputs (of non-zero length) are recycled if necessary. Attributes (see `attributes` such as `names` or `dim`) are copied from the first argument (if applicable, e.g., `not` for an S4 object).

`pmax.int` and `pmin.int` are faster internal versions only used when all arguments are atomic vectors and there are no classes: they drop all attributes. (Note that all versions fail for raw and complex vectors since these have no ordering.)

`max` and `min` are generic functions: methods can be defined for them individually or via the `Summary` group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.
By definition the min/max of a numeric vector containing an NaN is NaN, except that the min/max of any vector containing an NA is NA even if it also contains an NaN. Note that max(NA, Inf) == NA even though the maximum would be Inf whatever the missing value actually is.

Character versions are sorted lexicographically, and this depends on the collating sequence of the locale in use: the help for ‘Comparison’ gives details. The max/min of an empty character vector is defined to be character NA. (One could argue that as "" is the smallest character element, the maximum should be ", but there is no obvious candidate for the minimum.)

**Value**

For min or max, a length-one vector. For pmin or pmax, a vector of length the longest of the input vectors, or length zero if one of the inputs had zero length.

The type of the result will be that of the highest of the inputs in the hierarchy integer < double < character.

For min and max if there are only numeric inputs and all are empty (after possible removal of NAs), the result is double (Inf or -Inf).

**S4 methods**

min and max are part of the S4 Summary group generic. Methods for them must use the signature x, ..., na.rm.

**Note**

‘Numeric’ arguments are vectors of type integer and numeric, and logical (coerced to integer). For historical reasons, NULL is accepted as equivalent to integer(0).

pmax and pmin will also work on classed S3 or S4 objects with appropriate methods for comparison, i.e. na and rep (if recycling of arguments is needed).

**References**

**See Also**

range (both min and max) and which.min (which.max) for the arg min, i.e., the location where an extreme value occurs.

‘plotmath’ for the use of min in plot annotation.

**Examples**

```r
require(stats); require(graphics)
min(5:1, pi) #-> one number
pmin(5:1, pi) #-> 5 numbers

x <- sort(rnorm(100)); cH <- 1.35
pmin(cH, quantile(x)) # no names
pmin(quantile(x), cH) # has names
plot(x, pmin(cH, pmax(-cH, x)), type = "b", main = "Huber's function")

cut01 <- function(x) pmax(pmin(x, 1), 0)
curve( x^2 - 1/4, -1.4, 1.5, col = 2)
```
curve(cut01(x^2 - 1/4), col = "blue", add = TRUE, n = 500)
## pmax(), pmin() preserve attributes of *first* argument
D <- diag(x = (3:1)/4) ; n0 <- numeric()
stopifnot(identical(D, cut01(D) ),
  identical(n0, cut01(n0)),
  identical(n0, cut01(NULL)),
  identical(n0, pmax(3:1, n0, 2)),
  identical(n0, pmax(n0, 4)))

---

extSoftVersion

Report Versions of Third-Party Software

Description

Report versions of (external) third-party software used.

Usage

extSoftVersion()

Details

The reports the versions of third-party software libraries in use. These are often external but might have been compiled into R when it was installed.

With dynamic linking, these are the versions of the libraries linked to in this session: with static linking, of those compiled in.

Value

A named character vector, currently with components

- **zlib**: The version of zlib in use.
- **bzlib**: The version of bzlib (from bzip2) in use.
- **xz**: The version of liblzma (from xz) in use.
- **PCRE**: The version of PCRE in use.
- **ICU**: The version of ICU in use (if any, otherwise ").
- **TRE**: The version of libtre in use.
- **iconv**: The implementation and version of the iconv library in use (if known).
- **readline**: The version of readline in use (if any, otherwise ").
- **BLAS**: Name of the binary/executable file with the implementation of BLAS in use (if known, otherwise ").

Note that the values for bzlib and PCRE normally contain a date as well as the version number, and that for TRE includes several items separated by spaces, the version number being the second.

For iconv this will give the implementation as well as the version, for example "GNU libiconv 1.14", "glibc 2.18" or "win_iconv" (which has no version number).

The name of the binary/executable file for BLAS can be used as an indication of which implementation is in use. Typically, the R version of BLAS will appear as libR.so (libR.dylib), R or libRblas.so (libRblas.dylib), depending on how R was built. Note that libRblas.so
(libRblas.dylib) may also be shown for an external BLAS implementation that had been copied, hard-linked or renamed by the system administrator. For an external BLAS, a shared object file will be given and its path/name may indicate the vendor/version. The detection does not work on Windows.

See Also

libcurlVersion for the version of libCurl.

La_version for the version of LAPACK in use.

La_library for binary/executable file with LAPACK in use.

grSoftVersion for third-party graphics software.

tclVersion for the version of Tcl/Tk.

pcre_config for PCRE configuration options.

Examples

extSoftVersion()
## the PCRE version
sub(".*", ",", extSoftVersion()["PCRE"])

factor

Factors

Description

The function factor is used to encode a vector as a factor (the terms ‘category’ and ‘enumerated type’ are also used for factors). If argument ordered is TRUE, the factor levels are assumed to be ordered. For compatibility with S there is also a function ordered.

is.factor, is.ordered, as.factor and as.ordered are the membership and coercion functions for these classes.

Usage

factor(x = character(), levels, labels = levels,
       exclude = NA, ordered = is.ordered(x), nmax = NA)

ordered(x, ...)

is.factor(x)

is.ordered(x)

as.factor(x)

as.ordered(x)

ddNA(x, ifany = FALSE)
Arguments

- **x**: a vector of data, usually taking a small number of distinct values.
- **levels**: an optional vector of the unique values (as character strings) that x might have taken. The default is the unique set of values taken by `as.character(x)`, sorted into increasing order of x. Note that this set can be specified as smaller than `sort(unique(x))`.
- **labels**: either an optional character vector of labels for the levels (in the same order as levels after removing those in exclude), or a character string of length 1. Duplicated values in labels can be used to map different values of x to the same factor level.
- **exclude**: a vector of values to be excluded when forming the set of levels. This may be factor with the same level set as x or should be a character.
- **ordered**: logical flag to determine if the levels should be regarded as ordered (in the order given).
- **nmax**: an upper bound on the number of levels; see ‘Details’.
- **ifany**: (in ordered(.)): any of the above, apart from ordered itself.

Details

The type of the vector x is not restricted; it only must have an `as.character` method and be sortable (by `sort.list`).

Ordered factors differ from factors only in their class, but methods and the model-fitting functions treat the two classes quite differently.

The encoding of the vector happens as follows. First all the values in exclude are removed from levels. If x[i] equals levels[j], then the i-th element of the result is j. If no match is found for x[i] in levels (which will happen for excluded values) then the i-th element of the result is set to NA.

Normally the ‘levels’ used as an attribute of the result are the reduced set of levels after removing those in exclude, but this can be altered by supplying labels. This should either be a set of new labels for the levels, or a character string, in which case the levels are that character string with a sequence number appended.

`factor(x, exclude = NULL)` applied to a factor without NAs is a no-operation unless there are unused levels: in that case, a factor with the reduced level set is returned. If exclude is used, since R version 3.4.0, excluding non-existing character levels is equivalent to excluding nothing, and when exclude is a character vector, that is applied to the levels of x. Alternatively, exclude can be factor with the same level set as x and will exclude the levels present in exclude.

The codes of a factor may contain NA. For a numeric x, set exclude = NULL to make NA an extra level (prints as <NA>); by default, this is the last level.

If NA is a level, the way to set a code to be missing (as opposed to the code of the missing level) is to use `is.na` on the left-hand-side of an assignment (as in `is.na(f)[i] <- TRUE`; indexing inside `is.na` does not work). Under those circumstances missing values are currently printed as <NA>, i.e., identical to entries of level NA.

`is.factor` is generic: you can write methods to handle specific classes of objects, see Internal-Methods.

Where levels is not supplied, `unique` is called. Since factors typically have quite a small number of levels, for large vectors x it is helpful to supply nmax as an upper bound on the number of unique values.
Value

factor returns an object of class "factor" which has a set of integer codes the length of x with a "levels" attribute of mode character and unique (!anyDuplicated(.)) entries. If argument ordered is true (or ordered() is used) the result has class c("ordered", "factor"). Undocumentedly for a long time, factor(x) loses all attributes(x) but "names", and resets "levels" and "class".

Applying factor to an ordered or unordered factor returns a factor (of the same type) with just the levels which occur: see also [.factor for a more transparent way to achieve this.

is.factor returns TRUE or FALSE depending on whether its argument is of type factor or not. Correspondingly, is.ordered returns TRUE when its argument is an ordered factor and FALSE otherwise.

as.factor coerces its argument to a factor. It is an abbreviated (sometimes faster) form of factor.

as.ordered(x) returns x if this is ordered, and ordered(x) otherwise.

addNA modifies a factor by turning NA into an extra level (so that NA values are counted in tables, for instance).

.valid.factor(object) checks the validity of a factor, currently only levels(object), and returns TRUE if it is valid, otherwise a string describing the validity problem. This function is used for validObject(<factor>).

Warning

The interpretation of a factor depends on both the codes and the "levels" attribute. Be careful only to compare factors with the same set of levels (in the same order). In particular, as.numeric applied to a factor is meaningless, and may happen by implicit coercion. To transform a factor f to approximately its original numeric values, as.numeric(levels(f))[f] is recommended and slightly more efficient than as.numeric(as.character(f)).

The levels of a factor are by default sorted, but the sort order may well depend on the locale at the time of creation, and should not be assumed to be ASCII.

There are some anomalies associated with factors that have NA as a level. It is suggested to use them sparingly, e.g., only for tabulation purposes.

Comparison operators and group generic methods

There are "factor" and "ordered" methods for the group generic Ops which provide methods for the Comparison operators, and for the min, max, and range generics in Summary of "ordered". (The rest of the groups and the Math group generate an error as they are not meaningful for factors.)

Only == and != can be used for factors: a factor can only be compared to another factor with an identical set of levels (not necessarily in the same ordering) or to a character vector. Ordered factors are compared in the same way, but the general dispatch mechanism precludes comparing ordered and unordered factors.

All the comparison operators are available for ordered factors. Collation is done by the levels of the operands: if both operands are ordered factors they must have the same level set.

Note

In earlier versions of R, storing character data as a factor was more space efficient if there is even a small proportion of repeats. However, identical character strings now share storage, so the difference is small in most cases. (Integer values are stored in 4 bytes whereas each reference to a character string needs a pointer of 4 or 8 bytes.)
References

See Also

 [.factor for subsetting of factors.

gl for construction of balanced factors and C for factors with specified contrasts. levels and nlevels for accessing the levels, and unclass to get integer codes.

Examples

(ff <- factor(substring("statistics", 1:10, 1:10), levels = letters))

as.integer(ff)  # the internal codes

(f. <- factor(ff))  # drops the levels that do not occur

ff[, drop = TRUE]  # the same, more transparently

factor(letters[1:20], labels = "letter")

class(ordered(4:1))  # "ordered", inheriting from "factor"

z <- factor(LETTERS[3:1], ordered = TRUE)

## and "relational" methods work:

stopifnot(sort(z)[c(1,3)] == range(z), min(z) < max(z))

## suppose you want "NA" as a level, and to allow missing values.

(x <- factor(c(1, 2, NA), exclude = NULL))

is.na(x)[2] <- TRUE

x  # [1] 1 <NA> <NA>

is.na(x)

# [1] FALSE TRUE FALSE

## More rational, since R 3.4.0:

factor(c(1:2, NA), exclude = "")  # keeps <NA>, as

factor(c(1:2, NA), exclude = NULL)  # always did

## exclude = <character>

z  # ordered levels 'A < B < C'

factor(z, exclude = "C")  # does exclude

factor(z, exclude = "B")  # ditto

## Now, labels maybe duplicated:

## factor() with duplicated labels allowing to "merge levels"

x <- c("Man", "Male", "Man", "Lady", "Female")

## Map from 4 different values to only two levels:

(xf <- factor(x, levels = c("Male", "Man", "Lady", "Female"),

labels = c("Male", "Male", "Female", "Female")))

#> [1] Male Male Male Female Female

# Levels: Male Female

## Using addNA()

Month <- airquality$Month

table(addNA(Month))

table(addNA(Month, ifany = TRUE))
file.access

Ascertain File Accessibility

Description
Utility function to access information about files on the user’s file systems.

Usage
file.access(names, mode = 0)

Arguments
names character vector containing file names. Tilde-expansion will be done: see path.expand.
mode integer specifying access mode required: see ‘Details’.

Details
The mode value can be the exclusive or of the following values
0 test for existence.
1 test for execute permission.
2 test for write permission.
4 test for read permission.
Permission will be computed for real user ID and real group ID (rather than the effective IDs).
Please note that it is not a good idea to use this function to test before trying to open a file. On a multi-tasking system, it is possible that the accessibility of a file will change between the time you call file.access() and the time you try to open the file. It is better to wrap file open attempts in try.

Value
An integer vector with values 0 for success and -1 for failure.

Note
This is intended as a replacement for the S-PLUS function access, a wrapper for the C function of the same name, which explains the return value encoding. Note that the return value is false for success.

See Also
file.info for more details on permissions, Sys.chmod to change permissions, and try for a ‘test it and see’ approach.
file_test for shell-style file tests.

Examples
fa <- file.access(dir("."))
table(fa) # count successes & failures
file.choose

Choose a File Interactively

Description
Choose a file interactively.

Usage
file.choose(new = FALSE)

Arguments
new Logical: choose the style of dialog box presented to the user: at present only new = FALSE is used.

Value
A character vector of length one giving the file path.

See Also
- list.files for non-interactive selection.

file.info
Extract File Information

Description
Utility function to extract information about files on the user’s file systems.

Usage
file.info(..., extra_cols = TRUE)

file.mode(...)
file.mtime(...)
file.size(...)

Arguments
... character vectors containing file paths. Tilde-expansion is done: see path.expand.
extra_cols Logical: return all cols rather than just the first six.
Details

What constitutes a ‘file’ is OS-dependent but includes directories. (However, directory names must not include a trailing backslash or slash on Windows.) See also the section in the help for `file.exists` on case-insensitive file systems.

The file ‘mode’ follows POSIX conventions, giving three octal digits summarizing the permissions for the file owner, the owner’s group and for anyone respectively. Each digit is the logical or of read (4), write (2) and execute/search (1) permissions.

On most systems symbolic links are followed, so information is given about the file to which the link points rather than about the link.

Value

For `file.info`, data frame with row names the file names and columns

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>size</td>
<td>double: File size in bytes.</td>
</tr>
<tr>
<td>isdir</td>
<td>logical: Is the file a directory?</td>
</tr>
<tr>
<td>mode</td>
<td>integer of class &quot;octmode&quot;: The file permissions, printed in octal, for example 644.</td>
</tr>
<tr>
<td>mtime, ctime, atime</td>
<td>integer of class &quot;POSIXct&quot;: file modification, ‘last status change’ and last access times.</td>
</tr>
<tr>
<td>uid</td>
<td>integer: the user ID of the file’s owner.</td>
</tr>
<tr>
<td>gid</td>
<td>integer: the group ID of the file’s group.</td>
</tr>
<tr>
<td>uname</td>
<td>character: uid interpreted as a user name.</td>
</tr>
<tr>
<td>grname</td>
<td>character: gid interpreted as a group name.</td>
</tr>
</tbody>
</table>

Unknown user and group names will be NA.

If `extra.cols` is false, only the first six columns are returned: as these can all be found from a single C system call this can be faster. (However, properly configured systems will use a ‘name service cache daemon’ to speed up the name lookups.)

Entries for non-existent or non-readable files will be NA. The `uid`, `gid`, `uname` and `grname` columns may not be supplied on a non-POSIX Unix-alike system, and will not be on Windows.

What is meant by the three file times depends on the OS and file system. On Windows native file systems `ctime` is the file creation time (something which is not recorded on most Unix-alike file systems). What is meant by ‘file access’ and hence the ‘last access time’ is system-dependent.

The times are reported to an accuracy of seconds, and perhaps more on some systems. However, many file systems only record times in seconds, and some (e.g., modification time on FAT systems) are recorded in increments of 2 or more seconds.

`file.mode`, `file.mtime` and `file.size` are convenience wrappers returning just one of the columns.

Note

Some systems allow files of more than 2Gb to be created but not accessed by the `stat` system call. Such files will show up as non-readable (and very likely not be readable by any of R’s input functions) – fortunately such file systems are becoming rare.
See Also

Sys.readlink to find out about symbolic links, files, file.access, list.files, and DateTimeClasses for the date formats.
Sys.chmod to change permissions.

Examples

ncol(finf <- file.info(dir())) # at least six
finf # the whole list
## Those that are more than 100 days old:
finf <- file.info(dir(), extra.cols = FALSE)
finf[difftime(Sys.time(), finf[,"mtime"], units = "days") > 100 , 1:4]
file.info("no-such-file-exists")

Description

Construct the path to a file from components in a platform-independent way.

Usage

file.path(..., fsep = .Platform$file.sep)

Arguments

... character vectors.
fsep the path separator to use.

Details

The implementation is designed to be fast (faster than paste) as this function is used extensively in R itself.

It can also be used for environment paths such as PATH and R_LIBS with fsep = .Platform$path.sep.

Trailing path separators are invalid for Windows file paths apart from '/' and 'd:' (although some functions/utilities do accept them), so a trailing / or \ is removed.

Value

A character vector of the arguments concatenated term-by-term and separated by fsep if all arguments have positive length; otherwise, an empty character vector (unlike paste).

Note

The components are by default separated by / (not \) on Windows.
file.show  

Display One or More Text Files

Description

Display one or more (plain) text files, in a platform specific way, typically via a ‘pager’.

Usage

file.show(..., header = rep("", nfiles),
         title = "R Information",
         delete.file = FALSE, pager = getOption("pager"),
         encoding = "")

Arguments

... one or more character vectors containing the names of the files to be displayed. Paths with have tilde expansion.
header character vector (of the same length as the number of files specified in ...) giving a header for each file being displayed. Defaults to empty strings.
title an overall title for the display. If a single separate window is used for the display, title will be used as the window title. If multiple windows are used, their titles should combine the title and the file-specific header.
delete.file should the files be deleted after display? Used for temporary files.
pager the pager to be used: not used on all platforms
encoding character string giving the encoding to be assumed for the file(s).

Details

This function provides the core of the R help system, but it can be used for other purposes as well, such as page.

How the pager is implemented is highly system-dependent.

The basic Unix version concatenates the files (using the headers) to a temporary file, and displays it in the pager selected by the pager argument, which is a character vector specifying a system command (a full path or a command found on the PATH) to run on the set of files. The ‘factory-fresh’ default is to use ‘R_HOME/bin/pager’, which is a shell script running the command-line specified by the environment variable PAGER whose default is set at configuration, usually to less. On a Unix-alike more is used if pager is empty.

Most GUI systems will use a separate pager window for each file, and let the user leave it up while R continues running. The selection of such pagers could either be done using special pager names being intercepted by lower-level code (such as “internal” and “console” on Windows), or by letting pager be an R function which will be called with arguments (files, header, title, delete.file) corresponding to the first four arguments of file.show and take care of interfacing to the GUI.

The R.app GUI on macOS uses its internal pager irrespective of the setting of pager.

Not all implementations will honour delete.file. In particular, using an external pager on Windows does not, as there is no way to know when the external application has finished with the file.

files, list.files, help: RShowDoc call file.show() for type = "text". Consider
getOption("pdfviewer") and e.g., system for displaying pdf files.
file.edit.

Examples

file.show(file.path(R.home("doc"), "COPYRIGHTS"))

Description
These functions provide a low-level interface to the computer’s file system.

Usage

file.create(..., showWarnings = TRUE)
file.exists(...) file.rename(from, to)
file.append(file1, file2)
file.copy(from, to, overwrite = recursive, recursive = FALSE,
    copy.mode = TRUE, copy.date = FALSE)
file.symlink(from, to)
file.link(from, to)

Arguments

..., file1, file2 character vectors, containing file names or paths.
from, to character vectors, containing file names or paths. For file.copy and
file.symlink to can alternatively be the path to a single existing directory.
overwrite logical; should existing destination files be overwritten?
showWarnings logical; should the warnings on failure be shown?
recursive logical. If to is a directory, should directories in from be copied (and their
contents)? (Like cp -R on POSIX OSes.)
copy.mode logical: should file permission bits be copied where possible?
copy.date logical: should file dates be preserved where possible? See Sys.setFileTime.
Details

The ... arguments are concatenated to form one character string: you can specify the files separately or as one vector. All of these functions expand path names: see `path.expand`.

`file.create` creates files with the given names if they do not already exist and truncates them if they do. They are created with the maximal read/write permissions allowed by the `umask` setting (where relevant). By default a warning is given (with the reason) if the operation fails.

`file.exists` returns a logical vector indicating whether the files named by its argument exist. (Here 'exists' is in the sense of the system’s `stat` call: a file will be reported as existing only if you have the permissions needed by `stat`. Existence can also be checked by `file.access`, which might use different permissions and so obtain a different result. Note that the existence of a file does not imply that it is readable: for that use `file.access`.) What constitutes a 'file' is system-dependent, but should include directories. (However, directory names must not include a trailing backslash or slash on Windows.) Note that if the file is a symbolic link on a Unix-alike, the result indicates if the link points to an actual file, not just if the link exists. Lastly, note the different function `exists` which checks for existence of R objects.

`file.remove` attempts to remove the files named in its argument. On most Unix platforms 'file' includes empty directories, symbolic links, fifos and sockets. On Windows, 'file' means a regular file and not, say, an empty directory.

`file.rename` attempts to rename files (and `from` and to must be of the same length). Where file permissions allow this will overwrite an existing element of `to`. This is subject to the limitations of the OS's corresponding system call (see something like `man 2 rename` on a Unix-alike): in particular in the interpretation of 'file': most platforms will not rename files across file systems. (On Windows, `file.rename` can move files but not directories between volumes.) On platforms which allow directories to be renamed, typically neither or both of `from` and to must a directory, and if to exists it must be an empty directory.

`file.append` attempts to append the files named by its second argument to those named by its first. The R subscript recycling rule is used to align names given in vectors of different lengths.

`file.copy` works in a similar way to `file.append` but with the arguments in the natural order for copying. Copying to existing destination files is skipped unless `overwrite = TRUE`. The to argument can specify a single existing directory. If `copy.mode = TRUE` file read/write/execute permissions are copied where possible, restricted by `umask`. (On Windows this applies only to files.) Other security attributes such as ACLs are not copied. On a POSIX filesystem the targets of symbolic links will be copied rather than the links themselves, and hard links are copied separately. Using `copy.date = TRUE` may or may not copy the timestamp exactly (for example, fractional seconds may be omitted), but is more likely to do so as from R 3.4.0.

`file.symlink` and `file.link` make symbolic and hard links on those file systems which support them. For `file.symlink` the `to` argument can specify a single existing directory. (Unix and macOS native filesystems support both. Windows has hard links to files on NTFS file systems and concepts related to symbolic links on recent versions: see the section below on the Windows version of this help page. What happens on a FAT or SMB-mounted file system is OS-specific.)

Value

These functions return a logical vector indicating which operation succeeded for each of the files attempted. Using a missing value for a file or path name will always be regarded as a failure.

If `showWarnings = TRUE`, `file.create` will give a warning for an unexpected failure.
Case-insensitive file systems

Case-insensitive file systems are the norm on Windows and macOS, but can be found on all OSes (for example a FAT-formatted USB drive is probably case-insensitive).

These functions will most likely match existing files regardless of case on such file systems: however this is an OS function and it is possible that file names might be mapped to upper or lower case.

Warning

Always check the return value of these functions when used in package code. This is especially important for file.rename, which has OS-specific restrictions (and note that the session temporary directory is commonly on a different file system from the working directory).

setwd("..")
unlink("tmp", recursive = TRUE)
file.remove("A", "B", "C")
Manipulation of Directories and File Permissions

Description

These functions provide a low-level interface to the computer’s file system.

Usage

```r
dir.exists(paths)
dir.create(path, showWarnings = TRUE, recursive = FALSE, mode = "0777")
Sys.chmod(paths, mode = "0777", use_umask = TRUE)
Sys.umask(mode = NA)
```

Arguments

- `path`: a character vector containing a single path name. Tilde expansion (see `path.expand`) is done.
- `paths`: character vectors containing file or directory paths. Tilde expansion (see `path.expand`) is done.
- `showWarnings`: logical; should the warnings on failure be shown?
- `recursive`: logical. Should elements of the path other than the last be created? If true, like the Unix command `mkdir -p`.
- `mode`: the mode to be used on Unix-alikes: it will be coerced by `as.octmode`. For `Sys.chmod` it is recycled along `paths`.
- `use_umask`: logical: should the mode be restricted by the `umask` setting?

Details

dir.create creates the last element of the path, unless `recursive = TRUE`. Trailing path separators are discarded. The mode will be modified by the `umask` setting in the same way as for the system function `mkdir`. What modes can be set is OS-dependent, and it is unsafe to assume that more than three octal digits will be used. For more details see your OS’s documentation on the system call `mkdir`, e.g. `man 2 mkdir` (and not that on the command-line utility of that name).

One of the idiosyncrasies of Windows is that directory creation may report success but create a directory with a different name, for example `dir.create("G.S.")` creates "G.S". This is undocumented, and what are the precise circumstances is unknown (and might depend on the version of Windows). Also avoid directory names with a trailing space.

Sys.chmod sets the file permissions of one or more files. It may not be supported on a system (when a warning is issued). See the comments for `dir.create` for how modes are interpreted. Changing mode on a symbolic link is unlikely to work (nor be necessary). For more details see your OS’s documentation on the system call `chmod`, e.g. `man 2 chmod` (and not that on the command-line utility of that name). Whether this changes the permission of a symbolic link or its target is OS-dependent (although to change the target is more common, and POSIX does not support modes for symbolic links: BSD-based Unixes do, though).

Sys.umask sets the `umask` and returns the previous value: as a special case `mode = NA` just returns the current value. It may not be supported (when a warning is issued and "∅" is returned). For more details see your OS’s documentation on the system call `umask`, e.g. `man 2 umask`. 
How modes are handled depends on the file system, even on Unix-alikes (although their documentation is often written assuming a POSIX file system). So treat documentation cautiously if you are using, say, a FAT/FAT32 or network-mounted file system.

Value

dir.exists returns a logical vector of TRUE or FALSE values (without names).

dir.create and Sys.chmod return invisibly a logical vector indicating if the operation succeeded for each of the files attempted. Using a missing value for a path name will always be regarded as a failure. dir.create indicates failure if the directory already exists. If showWarnings = TRUE, dir.create will give a warning for an unexpected failure (e.g., not for a missing value nor for an already existing component for recursive = TRUE).

Sys.umask returns the previous value of the umask, as a length-one object of class \texttt{octmode}: the visibility flag is off unless mode is NA.

See also the section in the help for file.exists on case-insensitive file systems for the interpretation of path and paths.

Examples

## Not run:
## Fix up maximal allowed permissions in a file tree
Sys.chmod(list.dirs("."), "777")
f <- list.files(".", all.files = TRUE, full.names = TRUE, recursive = TRUE)
Sys.chmod(f, (file.info(f)$mode | "664"))

## End(Not run)
findInterval

Find Interval Numbers or Indices

Description

Given a vector of non-decreasing breakpoints in vec, find the interval containing each element of x; i.e., if i <- findInterval(x, v), for each index j in x v_i \leq x_j < v_{i+1} where v_0 := -\infty, v_{N+1} := +\infty, and N <- length(v). At the two boundaries, the returned index may differ by 1, depending on the optional arguments rightmost.closed and all.inside.

Usage

findInterval(x, vec, rightmost.closed = FALSE, all.inside = FALSE, left.open = FALSE)
**findInterval**

Arguments

- **x**: numeric.
- **vec**: numeric, sorted (weakly) increasingly, of length \( N \), say.
- **rightmost.closed**: logical; if true, the rightmost interval, \( \text{vec}[N-1] \ldots \text{vec}[N] \) is treated as closed, see below.
- **all.inside**: logical; if true, the returned indices are coerced into \( 1, \ldots, N-1 \), i.e., \( 0 \) is mapped to \( 1 \) and \( N \) to \( N-1 \).
- **left.open**: logical; if true all the intervals are open at left and closed at right; in the formulas below, \( \leq \) should be swapped with \( < \) (and \( > \) with \( \geq \)), and rightmost.closed means ‘leftmost is closed’\). This may be useful, e.g., in survival analysis computations.

Details

The function `findInterval` finds the index of one vector `x` in another, `vec`, where the latter must be non-decreasing. Where this is trivial, equivalent to `apply( outer(x, vec, ">="), 1, sum)`, as a matter of fact, the internal algorithm uses interval search ensuring \( O(n \log N) \) complexity where \( n \leftarrow \text{length}(x) \) (and \( N \leftarrow \text{length}(vec) \)). For (almost) sorted `x`, it will be even faster, basically \( O(n) \).

This is the same computation as for the empirical distribution function, and indeed, `findInterval(t, sort(X))` is identical to \( nF_n(t; X_1, \ldots, X_n) \) where \( F_n \) is the empirical distribution function of \( X_1, \ldots, X_n \).

When `rightmost.closed = TRUE`, the result for \( x[j] = \text{vec}[N] (= \text{max vec}) \), is \( N - 1 \) as for all other values in the last interval.

`left.open = TRUE` is occasionally useful, e.g., for survival data. For (anti-)symmetry reasons, it is equivalent to using “mirrored” data, i.e., the following is always true:

```r
identical(
  findInterval( x, v, left.open= TRUE, ... ),
  N - findInterval(-x, -v[N:1], left.open=FALSE, ...) )
```

where \( N \leftarrow \text{length}(vec) \) as above.

Value

vector of length \( \text{length}(x) \) with values in \( 0:N \) (and \( \text{NA} \)) where \( N \leftarrow \text{length}(vec) \), or values coerced to \( 1:(N-1) \) if and only if `all.inside = TRUE` (equivalently coercing all `x` values inside the intervals). Note that \( \text{NAs} \) are propagated from `x`, and \( \text{Inf} \) values are allowed in both `x` and `vec`.

  \text{cbind}(x, \text{findInterval}(x, v))
\end{align*}
\]

\[
\begin{align*}
  N & \leftarrow 100 \\
  X & \leftarrow \text{sort(\text{round(stats::rt(N, df = 2), 2)})} \\
  \text{tt} & \leftarrow c(-100, \text{seq(-2, 2, len = 201)}, +100) \\
  \text{it} & \leftarrow \text{findInterval}(\text{tt}, X) \\
  \text{tt}[\text{it} < 1 \mid \text{it} >= N] & \quad \# \text{only first and last are outside range(X)}
\end{align*}
\]

\[
\begin{align*}
  \text{#\# 'left.open = TRUE' means "mirroring" :} \\
  N & \leftarrow \text{length}(v) \\
  \text{stopifnot(identical(} \\
  & \quad \text{findInterval(} x, v, \text{left.open=TRUE) ,} \\
  & \quad N - \text{findInterval}(\text{-}x, v[N:1])))
\end{align*}
\]

\begin{verbatim}
force

<table>
<thead>
<tr>
<th>force</th>
<th>Force Evaluation of an Argument</th>
</tr>
</thead>
</table>

Description

Forces the evaluation of a function argument.

Usage

force(x)

Arguments

x

a formal argument of the enclosing function.

Details

\text{force}\ forces the evaluation of a formal argument. This can be useful if the argument will be captured in a closure by the lexical scoping rules and will later be altered by an explicit assignment or an implicit assignment in a loop or an apply function.

Note

This is semantic sugar: just evaluating the symbol will do the same thing (see the examples).

\text{force}\ does not force the evaluation of other promises. (It works by forcing the promise that is created when the actual arguments of a call are matched to the formal arguments of a closure, the mechanism which implements lazy evaluation.)

Examples

\[
\begin{align*}
  f & \leftarrow \text{function(y) function() y} \\
  \text{lf} & \leftarrow \text{vector("list", 5)} \\
  \text{for (i in seq.along(lf)) lf[[i]] <- f(i) } \\
  \text{lf[[1]]()} & \quad \# \text{returns 5}
\end{align*}
\]

\[
\begin{align*}
  g & \leftarrow \text{function(y) ( force(y); function() y )}
\end{align*}
\]
lg <- vector("list", 5)
for (i in seq_along(lg)) lg[[i]] <- g(i)
lg[[1]]() # returns 1

## This is identical to
g <- function(y) { y; function() y }

---

### forceAndCall

**Call a function with Some Arguments Forced**

**Description**

Call a function with a specified number of leading arguments forced before the call if the function is a closure.

**Usage**

```r
forceAndCall(n, FUN, ...)
```

**Arguments**

- `n`: number of leading arguments to force.
- `FUN`: function to call.
- `...`: arguments to `FUN`.

**Details**

forceAndCall calls the function `FUN` with arguments specified in `...`. If the value of `FUN` is a closure then the first `n` arguments to the function are evaluated (i.e. their delayed evaluation promises are forced) before executing the function body. If the value of `FUN` is a primitive then the call `FUN(...)` is evaluated in the usual way.

forceAndCall is intended to help defining higher order functions like `apply` to behave more reasonably when the result returned by the function applied is a closure that captured its arguments.

**See Also**

- `force`, `promise`, `closure`.

---

### Foreign

**Foreign Function Interface**

**Description**

Functions to make calls to compiled code that has been loaded into `R`.

**Usage**

```r
.C(.NAME, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
.Fortran(.NAME, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
```
Arguments

.NAME a character string giving the name of a C function or Fortran subroutine, or an object of class "NativeSymbolInfo", "RegisteredNativeSymbol" or "NativeSymbol" referring to such a name.

... arguments to be passed to the foreign function. Up to 65.

NAOK if TRUE then any NA or NaN or Inf values in the arguments are passed on to the foreign function. If FALSE, the presence of NA or NaN or Inf values is regarded as an error.

PACKAGE if supplied, confine the search for a character string .NAME to the DLL given by this argument (plus the conventional extension, '.so', '.dll', ...).

This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols, and also speeds up the search (see 'Note').

DUP, ENCODING For back-compatibility, accepted but ignored.

Details

These functions can be used to make calls to compiled C and Fortran 77 code. Later interfaces are .Call and .External which are more flexible and have better performance.

These functions are primitive, and .NAME is always matched to the first argument supplied (which should not be named). The other named arguments follow ... and so cannot be abbreviated. For clarity, should avoid using names in the arguments passed to ... that match or partially match .NAME.

Value

A list similar to the ... list of arguments passed in (including any names given to the arguments), but reflecting any changes made by the C or Fortran code.

Argument types

The mapping of the types of R arguments to C or Fortran arguments is

<table>
<thead>
<tr>
<th>R</th>
<th>C</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>int *</td>
<td>integer</td>
</tr>
<tr>
<td>numeric</td>
<td>double *</td>
<td>double precision</td>
</tr>
<tr>
<td>– or –</td>
<td>float *</td>
<td>real</td>
</tr>
<tr>
<td>complex</td>
<td>Rcomplex *</td>
<td>double complex</td>
</tr>
<tr>
<td>logical</td>
<td>int *</td>
<td>integer</td>
</tr>
<tr>
<td>character</td>
<td>char **</td>
<td>[see below]</td>
</tr>
<tr>
<td>raw</td>
<td>unsigned char *</td>
<td>not allowed</td>
</tr>
<tr>
<td>list</td>
<td>SEXP *</td>
<td>not allowed</td>
</tr>
<tr>
<td>other</td>
<td>SEXP</td>
<td>not allowed</td>
</tr>
</tbody>
</table>

Note: The C types corresponding to integer and logical are int, not long as in S. This difference matters on most 64-bit platforms, where int is 32-bit and long is 64-bit (but not on 64-bit Windows).

Note: The Fortran type corresponding to logical is integer, not logical: the difference matters on some Fortran compilers.
Numeric vectors in R will be passed as type double * to C (and as double precision to Fortran) unless the argument has attribute Csingle set to TRUE (use as.single or single). This mechanism is only intended to be used to facilitate the interfacing of existing C and Fortran code.

The C type Rcomplex is defined in 'Complex.h' as a typedef struct {double r; double i;}. It may or may not be equivalent to the C99 double complex type, depending on the compiler used.

Logical values are sent as 0 (FALSE), 1 (TRUE) or INT_MIN = -2147483648 (NA, but only if NAOK = TRUE), and the compiled code should return one of these three values: however non-zero values other than INT_MIN are mapped to TRUE.

Missing (NA) string values are passed to .C as the string "NA". As the C char type can represent all possible bit patterns there appears to be no way to distinguish missing strings from the string "NA". If this distinction is important use .Call.

.Fortran passes the first (only) character string of a character vector as a C character array to Fortran: that may be usable as character*255 if its true length is passed separately. Only up to 255 characters of the string are passed back. (How well this works, and even if it works at all, depends on the C and Fortran compilers and the platform.)

Lists, functions are other R objects can (for historical reasons) be passed to .C, but the .Call interface is much preferred. All inputs apart from atomic vectors should be regarded as read-only, and all apart from vectors (including lists), functions and environments are now deprecated.

Fortran symbol names

All Fortran compilers known to be usable to compile R map symbol names to lower case, and so does .Fortran.

Symbol names containing underscores are not valid Fortran 77 (although they are valid in Fortran 9x). Many Fortran 77 compilers will allow them but may translate them in a different way to names not containing underscores. Such names will often work with .Fortran (since how they are translated is detected when R is built and the information used by .Fortran), but portable code should not use Fortran names containing underscores.

Use .Fortran with care for compiled Fortran 9x code: it may not work if the Fortran 9x compiler used differs from the Fortran 77 compiler used when configuring R, especially if the subroutine name is not lower-case or includes an underscore. It is possible to use .C and do any necessary symbol-name translation yourself.

Copying of arguments

Character vectors are copied before calling the compiled code and to collect the results. For other atomic vectors the argument is copied before calling the compiled code if it is otherwise used in the calling code.

Non-atomic-vector objects are read-only to the C code and are never copied.

This behaviour can be changed by setting options(CBoundsCheck = TRUE). In that case raw, logical, integer, double and complex vector arguments are copied both before and after calling the compiled code. The first copy made is extended at each end by guard bytes, and on return it is checked that these are unaltered. For .C, each element of a character vector uses guard bytes.

Note

If one of these functions is to be used frequently, do specify PACKAGE (to confine the search to a single DLL) or pass .NAME as one of the native symbol objects. Searching for symbols can take a long time, especially when many namespaces are loaded.

You may see PACKAGE = "base" for symbols linked into R. Do not use this in your own code: such symbols are not part of the API and may be changed without warning.
formals

Access to and Manipulation of the Formal Arguments

Description
Get or set the formal arguments of a function.

Usage
formals(fun = sys.function(sys.parent()))
formals(fun, envir = environment(fun)) <- value

Arguments
fun a function, or see 'Details'.
envir environment in which the function should be defined.
value a list (or pairlist) of R expressions.

Details
For the first form, fun can also be a character string naming the function to be manipulated, which is searched for from the parent frame. If it is not specified, the function calling formals is used. Only closures have formals, not primitive functions.

Value
formals returns the formal argument list of the function specified, as a pairlist, or NULL for a non-function or primitive.

The replacement form sets the formals of a function to the list/pairlist on the right hand side, and (potentially) resets the environment of the function.

See Also
formalArgs (from methods), a shortcut for names(formals(.)). args for a human-readable version, alist, body, function.

References

See Also
dyn.load, .Call.
The ‘Writing R Extensions’ manual.
Examples

```r
require(stats)
formals(lm)

## If you just want the names of the arguments, use formalArgs instead.
names(formals(lm))
methods::: formalArgs(lm)  # same

## formals returns a pairlist. Arguments with no default have type symbol (aka name).
str(formals(lm))

## formals returns NULL for primitive functions. Use it in combination with
## args for this case.
is.primitive("+")
formals("+")
formals(args("+"))

## You can overwrite the formal arguments of a function (though this is
## advanced, dangerous coding).
f <- function(x) a + b
formals(f) <- alist(a = , b = 3)
f  # function(a, b = 3) a + b
f(2)  # result = 5
```

Description

Format an R object for pretty printing.

Usage

```r
format(x, ...)
```

## Default S3 method:
format(x, trim = FALSE, digits = NULL, nsmall = 0L,
     justify = c("left", "right", "centre", "none"),
     width = NULL, na.encode = TRUE, scientific = NA,
     big.mark = ",", big.interval = 3L,
     small.mark = ",", small.interval = 5L,
     decimal.mark = getOption("OutDec"),
     zero.print = NULL, drop0trailing = FALSE, ...)

## S3 method for class 'data.frame'
format(x, ..., justify = "none")

## S3 method for class 'factor'
format(x, ...)

## S3 method for class 'AsIs'
format(x, width = 12, ...)
**Arguments**

- **x**: any R object (conceptually); typically numeric.
- **trim**: logical; if FALSE, logical, numeric and complex values are right-justified to a common width: if TRUE the leading blanks for justification are suppressed.
- **digits**: how many significant digits are to be used for numeric and complex x. The default, NULL, uses `getOption("digits")`. This is a suggestion: enough decimal places will be used so that the smallest (in magnitude) number has this many significant digits, and also to satisfy `nsmall`. (For the interpretation for complex numbers see `signif`.)
- **nsmall**: the minimum number of digits to the right of the decimal point in formatting real/complex numbers in non-scientific formats. Allowed values are $0 \leq nsmall \leq 20$.
- **justify**: should a character vector be left-justified (the default), right-justified, centred or left alone. Can be abbreviated.
- **width**: default method: the minimum field width or NULL or 0 for no restriction. AsIs method: the maximum field width for non-character objects. NULL corresponds to the default 12.
- **na.encode**: logical: should NA strings be encoded? Note this only applies to elements of character vectors, not to numerical, complex nor logical NAs, which are always encoded as "NA".
- **scientific**: Either a logical specifying whether elements of a real or complex vector should be encoded in scientific format, or an integer penalty (see `options("scipen")`). Missing values correspond to the current default penalty.
- **...**: further arguments passed to or from other methods.

**Details**

`format` is a generic function. Apart from the methods described here there are methods for dates (see `format.Date`), date-times (see `format.POSIXct`) and for other classes such as `format.octmode` and `format.dist`.

`format.data.frame` formats the data frame column by column, applying the appropriate method of `format` for each column. Methods for columns are often similar to `as.character` but offer more control. Matrix and data-frame columns will be converted to separate columns in the result, and character columns (normally all) will be given class "AsIs".

`format.factor` converts the factor to a character vector and then calls the default method (and so justify applies).

`format.AsIs` deals with columns of complicated objects that have been extracted from a data frame. Character objects and (atomic) matrices are passed to the default method (and so width does not apply). Otherwise it calls `toString` to convert the object to character (if a vector or list, element by element) and then right-justifies the result.

Justification for character vectors (and objects converted to character vectors by their methods) is done on display width (see `ncchar`), taking double-width characters and the rendering of special characters (as escape sequences, including escaping backslash but not double quote: see `print.default`) into account. Thus the width is as displayed by `print(quote = FALSE)` and not as displayed by `cat`. Character strings are padded with blanks to the display width of the widest.
(If na.encode = FALSE missing character strings are not included in the width computations and are not encoded.)

Numeric vectors are encoded with the minimum number of decimal places needed to display all the elements to at least the digits significant digits. However, if all the elements then have trailing zeroes, the number of decimal places is reduced until nsmall is reached or at least one element has a non-zero final digit; see also the argument documentation for big.*, small.*, etc, above. See the note in print.default about digits >= 16.

Raw vectors are converted to their 2-digit hexadecimal representation by as.character.

The internal code respects the option getOption("OutDec") for the ‘decimal mark’, so if this is set to something other than "." then it takes precedence over argument decimal.mark.

Value

An object of similar structure to x containing character representations of the elements of the first argument x in a common format, and in the current locale’s encoding.

For character, numeric, complex or factor x, dims and dimnames are preserved on matrices/arrays and names on vectors: no other attributes are copied.

If x is a list, the result is a character vector obtained by applying format.default(x, ...) to each element of the list (after unlisting elements which are themselves lists), and then collapsing the result for each element with paste(collapse = ", "). The defaults in this case are trim = TRUE, justify = "none" since one does not usually want alignment in the collapsed strings.

format.info indicates how an atomic vector would be formatted.

formatC, paste, as.character, sprintf, print, prettyNum, toString, encodeString.

Examples

format(1:10)
format(1:10, trim = TRUE)

zz <- data.frame("(row names)"= c("aaaaa", "b"), check.names = FALSE)
format(zz)
format(zz, justify = "left")

## use of nsmall
format(13.7)
format(13.7, nsmall = 3)
format(c(6.0, 13.1), digits = 2)
format(c(6.0, 13.1), digits = 2, nsmall = 1)

## use of scientific
format(2^31-1)
format(2^31-1, scientific = TRUE)

## a list
z <- list(a = letters[1:3], b = (-pi+0i)^((-2:2)/2), c = c(1,10,100,1000),
        d = c("a", "longer", "character", "string"),
        q = quote( a + b ), e = expression(1+x))
## can you find the "2" small differences?
(f1 <- format(z, digits = 2))
(f2 <- format(z, digits = 2, justify = "left", trim = FALSE))
f1 == f2 ## 2 FALSE, 4 TRUE

---

format.info

format(.) Information

Description

Information is returned on how format(x, digits, nsmall) would be formatted.

Usage

format.info(x, digits = NULL, nsmall = 0)

Arguments

x

an atomic vector; a potential argument of format(x, ...).

digits

how many significant digits are to be used for numeric and complex x. The default, NULL, uses getOption("digits").

nsmall

(see format(..., nsmall)).

Value

An integer vector of length 1, 3 or 6, say r.

For logical, integer and character vectors a single element, the width which would be used by format if width = NULL.

For numeric vectors:

r[1] width (in characters) used by format(x)

r[2] number of digits after decimal point.

r[3] in 0:2; if ≥1, exponential representation would be used, with exponent length of r[3]+1.

For a complex vector the first three elements refer to the real parts, and there are three further elements corresponding to the imaginary parts.

See Also

format (notably about digits >= 16), formatC.
format.pval

Examples

dd <- options("digits") ; options(digits = 7) #-- for the following
format.info(123) # 3 0 0
format.info(pi)   # 8 6 0
format.info(1e8)  # 5 0 1 - exponential "1e+08"
format.info(1e222) # 6 0 2 - exponential "1e+222"

x <- pi*10^c(-10,-2,0:2,8,20)
names(x) <- formatC(x, width = 1, digits = 3, format = "g")
cbind(sapply(x, format))
t(sapply(x, format.info))

## using at least 8 digits right of "."
 t(sapply(x, format.info, nsmall = 8))

# Reset old options:
options(dd)

format.pval

Format P Values

Description

format.pval is intended for formatting p-values.

Usage

format.pval(pv, digits = max(1, getOption("digits") - 2),
eps = .Machine$double.eps, na.form = "NA", ...)

Arguments

pv       a numeric vector.
digits   how many significant digits are to be used.
eps      a numerical tolerance: see 'Details'.
na.form  character representation of NAs.
...      further arguments to be passed to format such as nsmall.

Details

format.pval is mainly an auxiliary function for print.summary.lm etc., and does separate formatting for fixed, floating point and very small values; those less than eps are formatted as "< [eps]" (where '[eps]' stands for format(eps, digits)).

Value

A character vector.

Examples

format.pval(c(stats::runif(5), pi^100, NA))
format.pval(c(0.1, 0.0001, 1e-27))
212

formatC

formatC

Formatting Using C-style Formats

Description
Formatting numbers individually and flexibly, formatC() using C style format specifications.
prettyNum() is used for “prettifying” (possibly formatted) numbers, also in format.default.
.format.zeros(), an auxiliary function of prettyNum() re-formats the zeros in a vector x of
formatted numbers.
Usage
formatC(x, digits = NULL, width = NULL,
format = NULL, flag = "", mode = NULL,
big.mark = "", big.interval = 3L,
small.mark = "", small.interval = 5L,
decimal.mark = getOption("OutDec"),
preserve.width = "individual", zero.print = NULL,
drop0trailing = FALSE)
prettyNum(x, big.mark = "",
big.interval = 3L,
small.mark = "", small.interval = 5L,
decimal.mark = getOption("OutDec"), input.d.mark = decimal.mark,
preserve.width = c("common", "individual", "none"),
zero.print = NULL, drop0trailing = FALSE, is.cmplx = NA,
...)
.format.zeros(x, zero.print, nx = suppressWarnings(as.numeric(x)))
Arguments
x

an atomic numerical or character object, possibly complex only for
prettyNum(), typically a vector of real numbers. Any class is discarded, with a
warning.

digits

the desired number of digits after the decimal point (format = "f") or significant digits (format = "g", = "e" or = "fg").
Default: 2 for integer, 4 for real numbers. If less than 0, the C default of 6 digits
is used. If specified as more than 50, 50 will be used with a warning unless
format = "f" where it is limited to typically 324. (Not more than 15–21 digits
need be accurate, depending on the OS and compiler used. This limit is just a
precaution against segfaults in the underlying C runtime.)

width

the total field width; if both digits and width are unspecified, width defaults
to 1, otherwise to digits + 1. width = 0 will use width = digits, width < 0
means left justify the number in this field (equivalent to flag = "-"). If necessary, the result will have more characters than width. For character data this is
interpreted in characters (not bytes nor display width).

format

equal to "d" (for integers), "f", "e", "E", "g", "G", "fg" (for reals), or "s" (for
strings). Default is "d" for integers, "g" for reals.


"f" gives numbers in the usual xxx.xxx format; "e" and "E" give n.ddde+nn or n.dddE+nn (scientific format); "g" and "G" put x[i] into scientific format only if it saves space to do so.

"fg" uses fixed format as "f", but digits as the minimum number of **significant** digits. This can lead to quite long result strings, see examples below. Note that unlike **signif** this prints large numbers with more significant digits than digits. Trailing zeros are **dropped** in this format, unless flag contains "#".

**flag** for formatC, a character string giving a format modifier as in Kernighan and Ritchie (1988, page 243) or the C+99 standard. "0" pads leading zeros; "-" does left adjustment, others are "+", " " , and "#"; on some platform–locale combination, """" activates "thousands' grouping" for decimal conversion, and versions of 'glibc' allow "I" for integer conversion to use the locale’s alternative output digits, if any.

There can be more than one of these, in any order. Other characters used to have no effect for character formatting, but signal an error since R 3.4.0.

**mode** "double" (or "real"), "integer" or "character". Default: Determined from the storage mode of x.

**big.mark** character; if not empty used as mark between every big.interval decimals *before* (hence big) the decimal point.

**big.interval** see big.mark above; defaults to 3.

**small.mark** character; if not empty used as mark between every small.interval decimals *after* (hence small) the decimal point.

**small.interval** see small.mark above; defaults to 5.

**decimal.mark** the character to be used to indicate the numeric decimal point.

**input.d.mark** if x is **character**, the character known to have been used as the numeric decimal point in x.

**preserve.width** string specifying if the string widths should be preserved where possible in those cases where marks (big.mark or small.mark) are added. "common", the default, corresponds to **format**-like behavior whereas "individual" is the default in formatC(). Value can be abbreviated.

**zero.print** logical, character string or NULL specifying if and how zeros should be formatted specially. Useful for pretty printing 'sparse' objects.

**drop0trailing** logical, indicating if trailing zeros, i.e., "0" *after* the decimal mark, should be removed; also drops "e+00" in exponential formats.

**is.cmplx** optional logical, to be used when x is "character" to indicate if it stems from **complex** vector or not. By default (NA), x is checked to 'look like' complex.

**...** arguments passed to format.

**nx** numeric vector of the same length as x, typically the numbers of which the character vector x is the pre-format.

**Details**

If you set **format** it overrides the setting of **mode**, so formatC(123.45, **mode** = "double", **format** = "d") gives 123.

The rendering of scientific format is platform-dependent: some systems use n.ddde+nnn or n.dddenn rather than n.ddde+nnn.
formatC does not necessarily align the numbers on the decimal point, so formatC(c(6.11, 13.1), digits = 2, format = "fg") gives c("6.1", "13"). If you want common formatting for several numbers, use format.

prettyNum is the utility function for prettifying x. x can be complex (or format(<complex>), here. If x is not a character, format(x[1], ...) is applied to each element, and then it is left unchanged if all the other arguments are at their defaults. Use the input.d.mark argument for prettyNum(x) when x is a character vector not resulting from something like format(<number>) with a period as decimal mark.

Because gsub is used to insert the big.mark and small.mark, special characters need escaping. In particular, to insert a single backslash, use "\\".

The C doubles used for R numerical vectors have signed zeros, which formatC may output as -0, -0.000 ....

There is a warning if big.mark and decimal.mark are the same: that would be confusing to those reading the output.

Value

A character object of same size and attributes as x (after discarding any class), in the current locale’s encoding.

Unlike format, each number is formatted individually. Looping over each element of x, the C function sprintf(…) is called for numeric inputs (inside the C function str_signif).

formatC: for character x, do simple (left or right) padding with white space.

Note

The default for decimal.mark in formatC() was changed in R 3.2.0: for use within print methods in packages which might be used with earlier versions: use decimal.mark = getOption("OutDec") explicitly.

Author(s)

formatC was originally written by Bill Dunlap for S-PLUS, later much improved by Martin Maechler.

It was first adapted for R by Friedrich Leisch and since much improved by the R Core team.

## --> ..... "1001" "10001" on supported platforms 

if(doLC) ## revert, typically to "C": 
 Sys.setlocale("LC_NUMERIC", oldLC)

---

formatDL

Format Description Lists

Description
Format vectors of items and their descriptions as 2-column tables or LaTeX-style description lists.

Usage

formatDL(x, y, style = c("table", "list"),
          width = 0.9 * getOption("width"), indent = NULL)

Arguments

x
a vector giving the items to be described, or a list of length 2 or a matrix with 2 columns giving both items and descriptions.

y
a vector of the same length as x with the corresponding descriptions. Only used if x does not already give the descriptions.

style
a character string specifying the rendering style of the description information. Can be abbreviated. If "table", a two-column table with items and descriptions as columns is produced (similar to Texinfo's @table environment). If "list", a LaTeX-style tagged description list is obtained.

width
a positive integer giving the target column for wrapping lines in the output.

indent
a positive integer specifying the indentation of the second column in table style, and the indentation of continuation lines in list style. Must not be greater than width/2, and defaults to width/3 for table style and width/9 for list style.

Details
After extracting the vectors of items and corresponding descriptions from the arguments, both are coerced to character vectors.

In table style, items with more than indent - 3 characters are displayed on a line of their own.

Value
a character vector with the formatted entries.

Examples

## Provide a nice summary of the numerical characteristics of the
## machine R is running on:
writeLines(formatDL(unlist(.Machine)))

## Inspect Sys.getenv() results in "list" style (by default, these are
## printed in "table" style):
writeLines(formatDL(Sys.getenv(), style = "list"))
Description

These functions provide the base mechanisms for defining new functions in the R language.

Usage

function( arglist ) expr
return(value)

Arguments

arglist   Empty or one or more name or name=expression terms.
expr      An expression.
value     An expression.

Details

The names in an argument list can be back-quoted non-standard names (see ‘backquote’).

If value is missing, NULL is returned. If it is a single expression, the value of the evaluated expression is returned. (The expression is evaluated as soon as return is called, in the evaluation frame of the function and before any on.exit expression is evaluated.)

If the end of a function is reached without calling return, the value of the last evaluated expression is returned.

Technical details

This type of function is not the only type in R; they are called closures (a name with origins in LISP) to distinguish them from primitive functions.

A closure has three components, its formals (its argument list), its body (expr in the ‘Usage’ section) and its environment which provides the enclosure of the evaluation frame when the closure is used.

There is an optional further component if the closure has been byte-compiled. This is not normally user-visible, but it indicated when functions are printed.

References

args.
formals, body and environment for accessing the component parts of a function.
debug for debugging; using invisible inside return(.) for returning invisibly.
Examples
   norm <- function(x) sqrt(x%*%x)
   norm(1:4)
   # An anonymous function:
   (function(x, y){ z <- x^2 + y^2; x+y+z })(0:7, 1)

funprog

Common Higher-Order Functions in Functional Programming Languages

Description
Reduce uses a binary function to successively combine the elements of a given vector and a possibly
given initial value. Filter extracts the elements of a vector for which a predicate (logical) function
gives true. Find and Position give the first or last such element and its position in the vector,
respectively. Map applies a function to the corresponding elements of given vectors. Negate creates
the negation of a given function.

Usage
Reduce(f, x, init, right = FALSE, accumulate = FALSE)
Filter(f, x)
Find(f, x, right = FALSE, nomatch = NULL)
Map(f, ...)
Negate(f)
Position(f, x, right = FALSE, nomatch = NA_integer_)

Arguments
f
   a function of the appropriate arity (binary for Reduce, unary for Filter, Find
   and Position, k-ary for Map if this is called with k arguments). An arbitrary
   predicate function for Negate.

x
   a vector.

init
   an R object of the same kind as the elements of x.

right
   a logical indicating whether to proceed from left to right (default) or from right
to left.

accumulate
   a logical indicating whether the successive reduce combinations should be ac-
cumulated. By default, only the final combination is used.

nomatch
   the value to be returned in the case when “no match” (no element satisfying the
   predicate) is found.

... vectors.

Details
If init is given, Reduce logically adds it to the start (when proceeding left to right) or the end
of x, respectively. If this possibly augmented vector v has n > 1 elements, Reduce successively
applies f to the elements of v from left to right or right to left, respectively. i.e., a left reduce
computes \( l_1 = f(v_1, v_2), l_2 = f(l_1, v_3), \) etc., and returns \( l_{n-1} = f(l_{n-2}, v_n), \) and a right reduce
does \( r_{n-1} = f(v_{n-1}, v_n) \), \( r_{n-2} = f(v_{n-2}, r_{n-1}) \) and returns \( r_1 = f(v_1, r_2) \). (E.g., if \( v \) is the sequence \((2, 3, 4)\) and \( f \) is division, left and right reduce give \((2/3)/4 = 1/6\) and \(2/(3/4) = 8/3\), respectively.) If \( v \) has only a single element, this is returned; if there are no elements, NULL is returned. Thus, it is ensured that \( f \) is always called with 2 arguments.

The current implementation is non-recursive to ensure stability and scalability.

Reduce is patterned after Common Lisp’s reduce. A reduce is also known as a fold (e.g., in Haskell) or an accumulate (e.g., in the C++ Standard Template Library). The accumulative version corresponds to Haskell’s scan functions.

Filter applies the unary predicate function \( f \) to each element of \( x \), coercing to logical if necessary, and returns the subset of \( x \) for which this gives true. Note that possible NA values are currently always taken as false; control over NA handling may be added in the future. Filter corresponds to filter in Haskell or remove-if-not in Common Lisp.

Find and Position are patterned after Common Lisp’s find-if and position-if, respectively. If there is an element for which the predicate function gives true, then the first or last such element or its position is returned depending on whether \( \text{right} \) is false (default) or true, respectively. If there is no such element, the value specified by \( \text{nomatch} \) is returned. The current implementation is not optimized for performance.

Map is a simple wrapper to \texttt{mapply} which does not attempt to simplify the result, similar to Common Lisp’s mapcar (with arguments being recycled, however). Future versions may allow some control of the result type.

Negate corresponds to Common Lisp’s complement. Given a (predicate) function \( f \), it creates a function which returns the logical negation of what \( f \) returns.

See Also

Function \texttt{clusterMap} and \texttt{mcmapply} (not Windows) in package \texttt{parallel} provide parallel versions of \texttt{Map}.

Examples

```r
## A general-purpose adder:
add <- function(x) Reduce("+", x)
add(list(1, 2, 3))
## Like sum(), but can also used for adding matrices etc., as it will
## use the appropriate '+' method in each reduction step.
## More generally, many generics meant to work on arbitrarily many
## arguments can be defined via reduction:
FOO <- function(...) Reduce(FOO2, list(...))
FOO2 <- function(x, y) UseMethod("FOO2")
## FOO() methods can then be provided via FOO2() methods.

## A general-purpose cumulative adder:
cadd <- function(x) Reduce("+", x, accumulate = TRUE)
cadd(seq_len(7))

## A simple function to compute continued fractions:
cfrac <- function(x) Reduce(function(u, v) u + 1 / v, x, right = TRUE)
## Continued fraction approximation for pi:
cfrac(c(3, 7, 15, 1, 292))
## Continued fraction approximation for Euler's number (e):
cfrac(c(2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8))
## Iterative function application:
```
Funcall <- function(f, ...) f(...)
## Compute log(exp(acos(cos(0))
Reduce(Funcall, list(log, exp, acos, cos), 0, right = TRUE)
## n-fold iterate of a function, functional style:
Iterate <- function(f, n = 1)
  function(x) Reduce(Funcall, rep.int(list(f), n), x, right = TRUE)
## Continued fraction approximation to the golden ratio:
Iterate(function(x) 1 + 1 / x, 30)(1)
## which is the same as
cfrac(rep.int(1, 31))
## Computing square root approximations for x as fixed points of the
## function t |-> (t + x / t) / 2, as a function of the initial value:
asqrt <- function(x, n) Iterate(function(t) (t + x / t) / 2, n)
asqrt(2, 30)(10) # Starting from a positive value => +sqrt(2)
asqrt(2, 30)(-1) # Starting from a negative value => -sqrt(2)

## A list of all functions in the base environment:
funs <- Filter(is.function, sapply(ls(baseenv()), get, baseenv()))
## Functions in base with more than 10 arguments:
names(Filter(function(f) length(formals(f)) > 10, funs))
## Number of functions in base with a '...' argument:
length(Filter(function(f)
  any(names(formals(f)) %in% "..."),

**gc: Garbage Collection**

**Description**

A call of gc causes a garbage collection to take place. gcinfo sets a flag so that automatic collection is either silent (verbose = FALSE) or prints memory usage statistics (verbose = TRUE).

**Usage**

```
gc(verbose = getOption("verbose"), reset = FALSE, full = TRUE)
gcinfo(verbose)
```

**Arguments**

- **verbose** logical; if TRUE, the garbage collection prints statistics about cons cells and the space allocated for vectors.
- **reset** logical; if TRUE the values for maximum space used are reset to the current values.
- **full** logical; if TRUE a full collection is performed; otherwise only more recently allocated objects may be collected.
Details

A call of gc causes a garbage collection to take place. This will also take place automatically without user intervention, and the primary purpose of calling gc is for the report on memory usage. For an accurate report full = TRUE should be used.

It can be useful to call gc after a large object has been removed, as this may prompt R to return memory to the operating system.

R allocates space for vectors in multiples of 8 bytes: hence the report of "Vcells", a relict of an earlier allocator (that used a vector heap).

When gcinfo(TRUE) is in force, messages are sent to the message connection at each garbage collection of the form

Garbage collection 12 = 10+0+2 (level 0) ...
6.4 Mbytes of cons cells used (58%)
2.0 Mbytes of vectors used (32%)

Here the last two lines give the current memory usage rounded up to the next 0.1Mb and as a percentage of the current trigger value. The first line gives a breakdown of the number of garbage collections at various levels (for an explanation see the ‘R Internals’ manual).

Value

gc returns a matrix with rows "Ncells" (cons cells), usually 28 bytes each on 32-bit systems and 56 bytes on 64-bit systems, and "Vcells" (vector cells, 8 bytes each), and columns "used" and "gc trigger", each also interpreted in megabytes (rounded up to the next 0.1Mb).

If maxima have been set for either "Ncells" or "Vcells", a fifth column is printed giving the current limits in Mb (with NA denoting no limit).

The final two columns show the maximum space used since the last call to gc(reset = TRUE) (or since R started).
gcinfo returns the previous value of the flag.

The ‘R Internals’ manual.
Memory on R’s memory management, and gctorture if you are an R developer.
reg.finalizer for actions to happen at garbage collection.

Examples

gc() #-- do it now
gcinfo(TRUE) #-- in the future, show when R does it
x <- integer(100000); for(i in 1:18) x <- c(x, i)
gcinfo(verbos = FALSE) #-- don’t show it anymore

gc(TRUE)
gc(reset = TRUE)
**gc.time**  
*Report Time Spent in Garbage Collection*

**Description**
This function reports the time spent in garbage collection so far in the R session while GC timing was enabled.

**Usage**
```r
gc.time(on = TRUE)
```

**Arguments**
- `on` logical; if `TRUE`, GC timing is enabled.

**Details**
Due to timer resolution this may be under-estimate.  
This is a primitive.

**Value**
A numerical vector of length 5 giving the user CPU time, the system CPU time, the elapsed time and children's user and system CPU times (normally both zero), of time spent doing garbage collection whilst GC timing was enabled.

Times of child processes are not available on Windows and will always be given as `NA`.

**See Also**
- `gc`, `proc.time` for the timings for the session.

**Examples**
```r
gc.time()
```

---

**gctorture**  
*Torture Garbage Collector*

**Description**
Provokes garbage collection on (nearly) every memory allocation. Intended to ferret out memory protection bugs. Also makes R run very slowly, unfortunately.

**Usage**
```r
gctorture(on = TRUE)
gctorture2(step, wait = step, inhibit_release = FALSE)
```
**Arguments**

- `on` logical; turning it on/off.
- `step` integer; run GC every step allocations; `step = 0` turns the GC torture off.
- `wait` integer; number of allocations to wait before starting GC torture.
- `inhibit_release` logical; do not release free objects for re-use: use with caution.

**Details**

Calling `gctorture(TRUE)` instructs the memory manager to force a full GC on every allocation. `gctorture2` provides a more refined interface that allows the start of the GC torture to be deferred and also gives the option of running a GC only every `step` allocations.

The third argument to `gctorture2` is only used if R has been configured with a strict write barrier enabled. When this is the case all garbage collections are full collections, and the memory manager marks free nodes and enables checks in many situations that signal an error when a free node is used. This can help greatly in isolating unprotected values in C code. It does not detect the case where a node becomes free and is reallocated. The `inhibit_release` argument can be used to prevent such reallocation. This will cause memory to grow and should be used with caution and in conjunction with operating system facilities to monitor and limit process memory use.

`gctorture2` can also be invoked via environment variables at the start of the R session. `R_GCTORTURE` corresponds to the `step` argument, `R_GCTORTURE_WAIT` to `wait`, and `R_GCTORTURE_INHIBIT_RELEASE` to `inhibit_release`.

**Value**

Previous value of first argument.

---

**get**

*Return the Value of a Named Object*

**Description**

Search by name for an object (get) or zero or more objects (mget).

**Usage**

```r
get(x, pos = -1, envir = as.environment(pos), mode = "any", inherits = TRUE)

mget(x, envir = as.environment(-1), mode = "any", ifnotfound, inherits = FALSE)

dynGet(x, ifnotfound = , minframe = 1L, inherits = FALSE)
```
Arguments

- **x** For `get`, an object name (given as a character string).
- For `mget`, a character vector of object names.
- **pos, envir** where to look for the object (see ‘Details’); if omitted search as if the name of the object appeared unquoted in an expression.
- **mode** the mode or type of object sought: see the ‘Details’ section.
- **inherits** should the enclosing frames of the environment be searched?
- **ifnotfound** For `mget`, a list of values to be used if the item is not found: it will be coerced to a list if necessary.
- For `dynGet` any R object, e.g., a call to `stop()`.
- **minframe** integer specifying the minimal frame number to look into.

Details

The `pos` argument can specify the environment in which to look for the object in any of several ways: as a positive integer (the position in the search list); as the character string name of an element in the search list; or as an environment (including using `sys.frame` to access the currently active function calls). The default of -1 indicates the current environment of the call to `get`. The `envir` argument is an alternative way to specify an environment.

These functions look to see if each of the name(s) `x` have a value bound to it in the specified environment. If `inherits` is `TRUE` and a value is not found for `x` in the specified environment, the enclosing frames of the environment are searched until the name `x` is encountered. See `environment` and the ‘R Language Definition’ manual for details about the structure of environments and their enclosures.

If `mode` is specified then only objects of that type are sought. `mode` here is a mixture of the meanings of `typeof` and `mode`: "function" covers primitive functions and operators, "numeric", "integer" and "double" all refer to any numeric type, "symbol" and "name" are equivalent but "language" must be used (and not "call" or "(").

For `mget`, the values of `mode` and `ifnotfound` can be either the same length as `x` or of length 1. The argument `ifnotfound` must be a list containing either the value to use if the requested item is not found or a function of one argument which will be called if the item is not found, with argument the name of the item being requested.

`dynGet()` is somewhat experimental and to be used inside another function. It looks for an object in the callers, i.e., the `sys.frame()`s of the function. Use with caution.

Value

For `get`, the object found. If no object is found an error results.

For `mget`, a named list of objects (found or specified via `ifnotfound`).

Note

The reverse (or “inverse”) of `a <- get(nam)` is `assign(nam, a)`, assigning `a` to name `nam`.

`inherits = TRUE` is the default for `get` in R but not for S where it had a different meaning.

## test mget
e1 <- new.env()
mget(letters, e1, ifnotfound = as.list(LETTERS))

getDLLRegisteredRoutines

Reflectance Information for C/Fortran routines in a DLL

Description

This function allows us to query the set of routines in a DLL that are registered with R to enhance dynamic lookup, error handling when calling native routines, and potentially security in the future. This function provides a description of each of the registered routines in the DLL for the different interfaces, i.e. .C, .Call, .Fortran and .External.

Usage

getDLLRegisteredRoutines(dll, addNames = TRUE)

Arguments

dll a character string or DLLInfo object. The character string specifies the file name of the DLL of interest, and is given without the file name extension (e.g., the `.dll` or `.so`) and with no directory/path information. So a file `MyPackage/libs/MyPackage.so` would be specified as `MyPackage`.
The DLLInfo objects can be obtained directly in calls to dyn.load and library.dynam, or can be found after the DLL has been loaded using getLoadedDLLs, which returns a list of DLLInfo objects (index-able by DLL file name).
The DLLInfo approach avoids any ambiguities related to two DLLs having the same name but corresponding to files in different directories.

addNames a logical value. If this is TRUE, the elements of the returned lists are named using the names of the routines (as seen by R via registration or raw name). If FALSE, these names are not computed and assigned to the lists. As a result, the call should be quicker. The name information is also available in the NativeSymbolInfo objects in the lists.
Details

This takes the registration information after it has been registered and processed by the R internals. In other words, it uses the extended information.

There is `print` methods for the class, which prints only the types which have registered routines.

Value

A list of class "DLLRegisteredRoutines" with four elements corresponding to the routines registered for the `.C`, `.Call`, `.Fortran` and `.External` interfaces. Each is a list with as many elements as there were routines registered for that interface.

Each element identifies a routine and is an object of class "NativeSymbolInfo". An object of this class has the following fields:

- `name`: the registered name of the routine (not necessarily the name in the C code).
- `address`: the memory address of the routine as resolved in the loaded DLL. This may be `NULL` if the symbol has not yet been resolved.
- `dll`: an object of class DLLInfo describing the DLL. This is same for all elements returned.
- `numParameters`: the number of arguments the native routine is to be called with. In the future, we will provide information about the types of the parameters also.

Examples

dlls <- getLoadedDLLs()
getDLLRegisteredRoutines(dlls[["base"]])
getDLLRegisteredRoutines("stats")
getLoadedDLLs

Get DLLs Loaded in Current Session

Description

This function provides a way to get a list of all the DLLs (see `dyn.load`) that are currently loaded in the R session.

Usage

`getLoadedDLLs()`

Details

This queries the internal table that manages the DLLs.

Value

An object of class "DLLInfoList" which is a `list` with an element corresponding to each DLL that is currently loaded in the session. Each element is an object of class "DLLInfo" which has the following entries.

- `name` the abbreviated name.
- `path` the fully qualified name of the loaded DLL.
- `dynamicLookup` a logical value indicating whether R uses only the registration information to resolve symbols or whether it searches the entire symbol table of the DLL.
- `handle` a reference to the C-level data structure that provides access to the contents of the DLL. This is an object of class "DLLHandle".

Note that the class DLLInfo has a method for `$` which can be used to resolve native symbols within that DLL. Therefore, one must access the R-level elements described above using `[[`, e.g. `x[['name']]` or `x[['handle']]`.

Note

We are starting to use the `handle` elements in the DLL object to resolve symbols more directly in R.

```
getNativeSymbolInfo

Obtain a Description of one or more Native (C/Fortran) Symbols

Description

This finds and returns a description of one or more dynamically loaded or ‘exported’ built-in native symbols. For each name, it returns information about the name of the symbol, the library in which it is located and, if available, the number of arguments it expects and by which interface it should be called (i.e .Call, .C, .Fortran, or .External). Additionally, it returns the address of the symbol and this can be passed to other C routines. Specifically, this provides a way to explicitly share symbols between different dynamically loaded package libraries. Also, it provides a way to query where symbols were resolved, and aids diagnosing strange behavior associated with dynamic resolution.

Usage

getNativeSymbolInfo(name, PACKAGE, unlist = TRUE,
                       withRegistrationInfo = FALSE)

Arguments

name    the name(s) of the native symbol(s).
PACKAGE an optional argument that specifies to which DLL to restrict the search for this symbol. If this is "base", we search in the R executable itself.
unlist  a logical value which controls how the result is returned if the function is called with the name of a single symbol. If unlist is TRUE and the number of symbol names in name is one, then the NativeSymbolInfo object is returned. If it is FALSE, then a list of NativeSymbolInfo objects is returned. This is ignored if the number of symbols passed in name is more than one. To be compatible with earlier versions of this function, this defaults to TRUE.
withRegistrationInfo
           a logical value indicating whether, if TRUE, to return information that was registered with R about the symbol and its parameter types if such information is available, or if FALSE to return just the address of the symbol.

Details

This uses the same mechanism for resolving symbols as is used in all the native interfaces (.Call, etc.). If the symbol has been explicitly registered by the DLL in which it is contained, information about the number of arguments and the interface by which it should be called will be returned. Otherwise, a generic native symbol object is returned.

Value

Generally, a list of NativeSymbolInfo elements whose elements can be indexed by the elements of name in the call. Each NativeSymbolInfo object is a list containing the following elements:

name    the name of the symbol, as given by the name argument.
**getNativeSymbolInfo**

**address**

If `withRegistrationInfo` is `FALSE`, this is the native memory address of the symbol which can be used to invoke the routine, and also to compare with other symbol addresses. This is an external pointer object and of class `NativeSymbol`. If `withRegistrationInfo` is `TRUE` and registration information is available for the symbol, then this is an object of class `RegisteredNativeSymbol` and is a reference to an internal data type that has access to the routine pointer and registration information. This too can be used in calls to `.Call`, `.C`, `.Fortran` and `.External`.

**package**

A list containing 3 elements:

- **name** the short form of the library name which can be used as the value of the `PACKAGE` argument in the different native interface functions.
- **path** the fully qualified name of the DLL.
- **dynamicLookup** a logical value indicating whether dynamic resolution is used when looking for symbols in this library, or only registered routines can be located.

If the routine was explicitly registered by the dynamically loaded library, the list contains a fourth field

- **numParameters** the number of arguments that should be passed in a call to this routine.

Additionally, the list will have an additional class, being `CRoutine`, `CallRoutine`, `FortranRoutine` or `ExternalRoutine` corresponding to the R interface by which it should be invoked.

If any of the symbols is not found, an error is raised.

If `name` contains only one symbol name and `unlist` is `TRUE`, then the single `NativeSymbolInfo` is returned rather than the list containing that one element.

**Note**

One motivation for accessing this reflectance information is to be able to pass native routines to C routines as function pointers in C. This allows us to treat native routines and R functions in a similar manner, such as when passing an R function to C code that makes callbacks to that function at different points in its computation (e.g., `nls`). Additionally, we can resolve the symbol just once and avoid resolving it repeatedly or using the internal cache.

gettext

Translate Text Messages

Description

If Native Language Support was enabled in this build of R, attempt to translate character vectors or set where the translations are to be found.

Usage

gettext(..., domain = NULL)
ngettext(n, msg1, msg2, domain = NULL)
bindtextdomain(domain, dirname = NULL)

Arguments

... One or more character vectors.
domain The ‘domain’ for the translation.
n a non-negative integer.
msg1 the message to be used in English for n = 1.
msg2 the message to be used in English for n = 0, 2, 3, ....
dirname The directory in which to find translated message catalogs for the domain.

Details

If domain is NULL or "", and gettext or ngettext is called from a function in the namespace of package pkg the domain is set to "R-pkg". Otherwise there is no default domain.

If a suitable domain is found, each character string is offered for translation, and replaced by its translation into the current language if one is found. The value (logical) NA suppresses any translation.

Conventionally the domain for R warning/error messages in package pkg is "R-pkg", and that for C-level messages is "pkg".

For gettext, leading and trailing whitespace is ignored when looking for the translation.

ngettext is used where the message needs to vary by a single integer. Translating such messages is subject to very specific rules for different languages: see the GNU Gettext Manual. The string will often contain a single instance of %d to be used in sprintf. If English is used, msg1 is returned if n == 1 and msg2 in all other cases.

bindtextdomain is a wrapper for the C function of the same name: your system may have a man page for it. With a non-NULL dirname it specifies where to look for message catalogues: with domain = NULL it returns the current location.

Value

For gettext, a character vector, one element per string in .... If translation is not enabled or no domain is found or no translation is found in that domain, the original strings are returned.

For ngettext, a character string.

For bindtextdomain, a character string giving the current base directory, or NULL if setting it failed.
**getwd**

Get or Set Working Directory

**Description**

getwd returns an absolute filepath representing the current working directory of the R process; setwd(dir) is used to set the working directory to dir.

**Usage**

```r
getwd()
setwd(dir)
```

**Arguments**

- `dir` A character string: tilde expansion will be done.

**Examples**

```r
bindtextdomain("R")  # non-null if and only if NLS is enabled

for(n in 0:3)
  print(sprintf(ngettext(n, "%d variable has missing values", "%d variables have missing values"), n))

## Not run:
## for translation, those strings should appear in R-pkg.pot as
msgid "%d variable has missing values"
msgid_plural "%d variables have missing values"
msgstr[0]"
msgstr[1]"

## End(Not run)

miss <- c("one", "or", "another")
cat(ngettext(length(miss), "variable", "variables"),
PASTE(sQuote(miss), collapse = ", "),
ngettext(length(miss), "contains", "contain"), "missing values\n")

## better for translators would be to use

cat(sprintf(ngettext(length(miss),
  "variable %s contains missing values\n",
  "variables %s contain missing values\n"),
PASTE(sQuote(miss), collapse = ", ")))
```
Value

getwd returns a character string or NULL if the working directory is not available. On Windows the path returned will use / as the path separator and be encoded in UTF-8. The path will not have a trailing / unless it is the root directory (of a drive or share on Windows).

setwd returns the current directory before the change, invisibly and with the same conventions as getwd. It will give an error if it does not succeed (including if it is not implemented).

Note

Note that the return value is said to be an absolute filepath: there can be more than one representation of the path to a directory and on some OSes the value returned can differ after changing directories and changing back to the same directory (for example if symbolic links have been traversed).

See Also

list.files for the contents of a directory.
normalizePath for a ‘canonical’ path name.

Examples

(WD <- getwd())
if (!is.null(WD)) setwd(WD)

---

gl

Generate Factor Levels

Description

Generate factors by specifying the pattern of their levels.

Usage

gl(n, k, length = n*k, labels = seq_len(n), ordered = FALSE)

Arguments

n an integer giving the number of levels.
k an integer giving the number of replications.
length an integer giving the length of the result.
labels an optional vector of labels for the resulting factor levels.
ordered a logical indicating whether the result should be ordered or not.

Value

The result has levels from 1 to n with each value replicated in groups of length k out to a total length of length.

gl is modelled on the GLIM function of the same name.
See Also

The underlying `factor()`.

Examples

```r
## First control, then treatment:
gl(2, 8, labels = c("Control", "Treat"))
## 20 alternating 1s and 2s
gl(2, 1, 20)
## alternating pairs of 1s and 2s
gl(2, 2, 20)
```

Description

grep, grepl, regexpr, gregexpr and regexec search for matches to argument pattern within each element of a character vector: they differ in the format of and amount of detail in the results. sub and gsub perform replacement of the first and all matches respectively.

Usage

```r
grep(pattern, x, ignore.case = FALSE, perl = FALSE, value = FALSE,
     fixed = FALSE, useBytes = FALSE, invert = FALSE)

grepl(pattern, x, ignore.case = FALSE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)

sub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)

gsub(pattern, replacement, x, ignore.case = FALSE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)

regexpr(pattern, text, ignore.case = FALSE, perl = FALSE,
         fixed = FALSE, useBytes = FALSE)

gregexpr(pattern, text, ignore.case = FALSE, perl = FALSE,
         fixed = FALSE, useBytes = FALSE)

regexec(pattern, text, ignore.case = FALSE, perl = FALSE,
         fixed = FALSE, useBytes = FALSE)
```

Arguments

- `pattern`: character string containing a regular expression (or character string for `fixed = TRUE`) to be matched in the given character vector. Coerced by `as.character` to a character string if possible. If a character vector of length 2 or more is supplied, the first element is used with a warning. Missing values are allowed except for `regexpr` and `gregexpr`. 
grep

x, text a character vector where matches are sought, or an object which can be coerced by as.character to a character vector. Long vectors are supported.

ignore.case if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.

perl logical. Should Perl-compatible regexps be used?

value if FALSE, a vector containing the (integer) indices of the matches determined by grep is returned, and if TRUE, a vector containing the matching elements themselves is returned.

fixed logical. If TRUE, pattern is a string to be matched as is. Overrides all conflicting arguments.

useBytes logical. If TRUE the matching is done byte-by-byte rather than character-by-character. See ‘Details’.

invert logical. If TRUE return indices or values for elements that do not match.

replacement a replacement for matched pattern in sub and gsub. Coerced to character if possible. For fixed = FALSE this can include backreferences \"\" to \"\"9 to parenthesized subexpressions of pattern. For perl = TRUE only, it can also contain \"\U\" or \"\L\" to convert the rest of the replacement to upper or lower case and \"\E\" to end case conversion. If a character vector of length 2 or more is supplied, the first element is used with a warning. If NA, all elements in the result corresponding to matches will be set to NA.

Details

Arguments which should be character strings or character vectors are coerced to character if possible.

Each of these functions operates in one of three modes:

1. fixed = TRUE: use exact matching.
2. perl = TRUE: use Perl-style regular expressions.
3. fixed = FALSE, perl = FALSE: use POSIX 1003.2 extended regular expressions (the default).

See the help pages on regular expression for details of the different types of regular expressions.

The two sub functions differ only in that sub replaces only the first occurrence of a pattern whereas gsub replaces all occurrences. If replacement contains backreferences which are not defined in pattern the result is undefined (but most often the backreference is taken to be \"\")

For regexpr, gregexpr and regexec it is an error for pattern to be NA, otherwise NA is permitted and gives an NA match.

The main effect of useBytes is to avoid errors/warnings about invalid inputs and spurious matches in multibyte locales, but for regexpr it changes the interpretation of the output. It inhibits the conversion of inputs with marked encodings, and is forced if any input is found which is marked as "bytes" see Encoding).

Caseless matching does not make much sense for bytes in a multibyte locale, and you should expect it only to work for ASCII characters if useBytes = TRUE.

regexpr and gregexpr with perl = TRUE allow Python-style named captures, but not for long vector inputs.

Invalid inputs in the current locale are warned about up to 5 times.

Caseless matching with perl = TRUE for non-ASCII characters depends on the PCRE library being compiled with ‘Unicode property support’: an external library might not be.
Value

grep(value = FALSE) returns a vector of the indices of the elements of x that yielded a match (or not, for invert = TRUE). This will be an integer vector unless the input is a long vector, when it will be a double vector.
grep(value = TRUE) returns a character vector containing the selected elements of x (after coercion, preserving names but no other attributes).
grepl returns a logical vector (match or not for each element of x).
sub and gsub return a character vector of the same length and with the same attributes as x (after possible coercion to character). Elements of character vectors x which are not substituted will be returned unchanged (including any declared encoding). If useBytes = FALSE a non-ASCII substituted result will often be in UTF-8 with a marked encoding (e.g., if there is a UTF-8 input, and in a multibyte locale unless fixed = TRUE). Such strings can be re-encoded by enc2native.
regexpr returns an integer vector of the same length as text giving the starting position of the first match or −1 if there is none, with attribute "match.length", an integer vector giving the length of the matched text (or −1 for no match). The match positions and lengths are in characters unless useBytes = TRUE is used, when they are in bytes (as they are for an ASCII-only matching: in either case an attribute useBytes with value TRUE is set on the result). If named capture is used there are further attributes "capture.start", "capture.length" and "capture.names".
gregexpr returns a list of the same length as text each element of which is of the same form as the return value for regexpr, except that the starting positions of every (disjoint) match are given.
regexec returns a list of the same length as text each element of which is either −1 if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of pattern, with attribute "match.length" a vector giving the lengths of the matches (or −1 for no match). The interpretation of positions and length and the attributes follows regexpr.

Where matching failed because of resource limits (especially for PCRE) this is regarded as a non-match, usually with a warning.

Warning

The POSIX 1003.2 mode of gsub and gregexpr does not work correctly with repeated word-boundaries (e.g., pattern = "\\b"). Use perl = TRUE for such matches (but that may not work as expected with non-ASCII inputs, as the meaning of ‘word’ is system-dependent).

Performance considerations

If you are doing a lot of regular expression matching, including on very long strings, you will want to consider the options used. Generally PCRE will be faster than the default regular expression engine, and fixed = TRUE faster still (especially when each pattern is matched only a few times).
If you are working in a single-byte locale and have marked UTF-8 strings that are representable in that locale, convert them first as just one UTF-8 string will force all the matching to be done in Unicode, which attracts a penalty of around 3 × for the default POSIX 1003.2 mode.
If you can make use of useBytes = TRUE, the strings will not be checked before matching, and the actual matching will be faster. Often byte-based matching suffices in a UTF-8 locale since byte patterns of one character never match part of another.
PCRE-based matching by default puts additional effort into ‘studying’ the compiled pattern when x/text has length at least 10. As from R 3.4.0 that study may use the PCRE JIT compiler on platforms where it is available (see pcre_config). The details are controlled by options PCRE_study and PCRE_use_JIT. (Some timing comparisons can be seen by running file ‘tests/PCRE.R’ in the
The C code for POSIX-style regular expression matching has changed over the years. As from R 2.10.0 (Oct 2009) the TRE library of Ville Laurikari (http://laurikari.net/tre/) is used. The POSIX standard does give some room for interpretation, especially in the handling of invalid regular expressions and the collation of character ranges, so the results will have changed slightly over the years.

For Perl-style matching PCRE (http://www.pcre.org) is used: again the results may depend (slightly) on the version of PCRE in use.

Examples

grep("[a-z]", letters)

```r
txt <- c("arm","foot","lefroo","bafooobar")
if(length(i <- grep("foo", txt)))
  cat("'foo' appears at least once in\n\t", txt, "\n")
i # 2 and 4
txt[i]
```

## Double all 'a' or 'b's; "\" must be escaped, i.e., 'doubled'
gsub("([ab])", "\1_\1_", "abc and ABC")

```r
txt <- c("The", "licenses", "for", "most", "software", "are", "designed", "to", "take", "away", "your", "freedom",
```
"to", "share", "and", "change", "it.", "By", "contrast", "the", "GNU", "General", "Public", "License", "is", "intended", "to", "guarantee", "your", "freedom", "to", "share", "and", "change", "free", "software", "--", "to", "make", "sure", "the", "software", "is", "free", "for", "all", "its", "users")

```
(i <- grep("[gu]", txt)) # indices
stopifnot(txt[i] == grep("[gu]", txt, value = TRUE))
```

```c
## Note that in locales such as en_US this includes B as the
collation order is aAbCcCdEe ...
(ot <- sub("[b-e]", ",", txt))
txt[ot != gsub("[b-e]", ",", txt)]# gsub does "global" substitution
txt[gsub("g","#", txt) !=
gsub("g","#", txt, ignore.case = TRUE)] # the "G" words

regexpr("en", txt)
```

```r
gregexpr("e", txt)
```

## Using grepl() for filtering
```r
## Find functions with argument names matching "warn":
findArgs <- function(env, pattern) {
  nms <- ls(envir = as.environment(env))
  nms <- nms[is.na(match(nms, c("F","T")))] # work around checking hack
  aa <- sapply(nms, function(.) { o <- get(.)
    if(is.function(o)) names(formals(o)) })
  iw <- sapply(aa, function(a) any(grepl(pattern, a, ignore.case=TRUE)))
  aa[iw]
}
```

```r
findArgs("package:base", "warn")
```

```r
## trim trailing white space
str <- "Now is the time"
sub("+$", ",", str) # spaces only
```

```r
## what is considered 'white space' depends on the locale.
sub("[[:space:]]+$", ",", str) # white space, POSIX-style
## what PCRE considered white space changed in version 8.34: see ?regex
sub("\\s+$", ",", str, perl = TRUE) # PCRE-style white space
```

```r
## capitalizing

txt <- "a test of capitalizing"
gsub("(\w)(\w*)", "\U\1\L\2", txt, perl=TRUE)
gsub("(\w)(\w*)", "\U\1", txt, perl=TRUE)

txt2 <- "useRs may fly into JFK or laGuardia"
gsub("(\w)(\w*)\w", "\w\"E\w\"", txt2, perl=TRUE)
gsub("(\w)(\w*)\w", "\w\w\w", txt2, perl=TRUE)
```

```r
## named capture
notables <- c(" Ben Franklin and Jefferson Davis",
  "Millard Fillmore")
# name groups 'first' and 'last'
name.rex <- "(?<first>[[:upper:]][[:lower:]]+) (?<last>[[:upper:]][[:lower:]]+)"
(parsed <- regexpr(name.rex, notables, perl = TRUE))
gregexpr(name.rex, notables, perl = TRUE)[[2]]
```
grepRaw

Pattern Matching for Raw Vectors

description

grepRaw searches for substring pattern matches within a raw vector x.

Usage

grepRaw(pattern, x, offset = 1L, ignore.case = FALSE, value = FALSE, fixed = FALSE, all = FALSE, invert = FALSE)

Arguments

pattern raw vector containing a regular expression (or fixed pattern for fixed = TRUE) to be matched in the given raw vector. Coerced by charToRaw to a character string if possible.
grepRaw

x a raw vector where matches are sought, or an object which can be coerced by charToRaw to a raw vector. Long vectors are not supported.
ignore.case if FALSE, the pattern matching is case sensitive and if TRUE, case is ignored during matching.
offset An integer specifying the offset from which the search should start. Must be positive. The beginning of line is defined to be at that offset so "^" will match there.
value logical. Determines the return value: see ‘Value’.
fixed logical. If TRUE, pattern is a pattern to be matched as is.
all logical. If TRUE all matches are returned, otherwise just the first one.
invert logical. If TRUE return indices or values for elements that do not match. Ignored (with a warning) unless value = TRUE.

Details

Unlike grep, seeks matching patterns within the raw vector x. This has implications especially in the all = TRUE case, e.g., patterns matching empty strings are inherently infinite and thus may lead to unexpected results.

The argument invert is interpreted as asking to return the complement of the match, which is only meaningful for value = TRUE. Argument offset determines the start of the search, not of the complement. Note that invert = TRUE with all = TRUE will split x into pieces delimited by the pattern including leading and trailing empty strings (consequently the use of regular expressions with "^" or "$" in that case may lead to less intuitive results).

Some combinations of arguments such as fixed = TRUE with value = TRUE are supported but are less meaningful.

Value

grepRaw(value = FALSE) returns an integer vector of the offsets at which matches have occurred. If all = FALSE then it will be either of length zero (no match) or length one (first matching position).

grepRaw(value = TRUE, all = FALSE) returns a raw vector which is either empty (no match) or the matched part of x.

grepRaw(value = TRUE, all = TRUE) returns a (potentially empty) list of raw vectors corresponding to the matched parts.

Source

The TRE library of Ville Laurikari (http://laurikari.net/tre/) is used except for fixed = TRUE.

See Also

regular expression (aka regexp) for the details of the pattern specification.
grep for matching character vectors.
Examples

grepRaw("no match", "textText") # integer(0): no match
grepRaw("adf", "adadfadfdadadf") # 3 - the first match
grepRaw("adf", "adadfadfdadadf", all=TRUE, fixed=TRUE)
## [1] 3 6 13 -- three matches

groupGeneric S3 Group Generic Functions

Description

Group generic methods can be defined for four pre-specified groups of functions, Math, Ops, Summary and Complex. (There are no objects of these names in base R, but there are in the methods package.)

A method defined for an individual member of the group takes precedence over a method defined for the group as a whole.

Usage

## S3 methods for group generics have prototypes:
Math(x, ...)
Ops(e1, e2)
Complex(z)
Summary(..., na.rm = FALSE)

Arguments

x, z, e1, e2 objects.
...
 further arguments passed to methods.
na.rm logical: should missing values be removed?

Details

There are four groups for which S3 methods can be written, namely the "Math", "Ops", "Summary" and "Complex" groups. These are not R objects in base R, but methods can be supplied for them and base R contains factor, data.frame and difftime methods for the first three groups. (There is also a ordered method for Ops, POSIXt and Date methods for Math and Ops, package_version methods for Ops and Summary, as well as a ts method for Ops in package stats.)

1. Group "Math":
   • abs, sign, sqrt,
     floor, ceiling, trunc,
     round, signif
   • exp, log, expm1, log1p,
     cos, sin, tan,
     cospi, sinpi, tanpi,
     acos, asin, atan
     cosh, sinh, tanh,
     acosh, asinh, atanh
   • lgamma, gamma, digamma, trigamma
Members of this group dispatch on `x`. Most members accept only one argument, but members `log`, `round` and `signif` accept one or two arguments, and `trunc` accepts one or more.

2. Group "Ops":
   - `+`, `-`, `*`, `/`, `^`, `%%`, `%/%`
   - `&`, `|`, `!`
   - `==`, `!=`, `<`, `<=`, `>`, `>=`, `""`

   This group contains both binary and unary operators (+, - and !): when a unary operator is encountered the Ops method is called with one argument and `e2` is missing.

   The classes of both arguments are considered in dispatching any member of this group. For each argument its vector of classes is examined to see if there is a matching specific (preferred) or `Ops` method. If a method is found for just one argument or the same method is found for both, it is used. If different methods are found, there is a warning about ‘incompatible methods’: in that case or if no method is found for either argument the internal method is used.

   Note that the `data.frame` methods for the comparison ("Compare": `==`, `<`, ...) and logic ("Logic": `&` | and !) operators return a logical matrix instead of a data frame, for convenience and back compatibility.

   If the members of this group are called as functions, any argument names are removed to ensure that positional matching is always used.

3. Group "Summary":
   - `all`, `any`
   - `sum`, `prod`
   - `min`, `max`
   - `range`

   Members of this group dispatch on the first argument supplied.

4. Group "Complex":
   - `Arg`, `Conj`, `Im`, `Mod`, `Re`

   Members of this group dispatch on `z`.

Note that a method will be used for one of these groups or one of its members only if it corresponds to a "class" attribute, as the internal code dispatches on `oldClass` and not on `class`. This is for efficiency: having to dispatch on, say, `Ops.integer` would be too slow.

The number of arguments supplied for primitive members of the "Math" group generic methods is not checked prior to dispatch.

There is no lazy evaluation of arguments for group-generic functions.

**Technical Details**

These functions are all primitive and internal generic.

The details of method dispatch and variables such as `.Generic` are discussed in the help for `UseMethod`. There are a few small differences:

- For the operators of group `Ops`, the object `.Method` is a length-two character vector with elements the methods selected for the left and right arguments respectively. (If no method was selected, the corresponding element is "".)

- Object `.Group` records the group used for dispatch (if a specific method is used this is ").
Note

Package `methods` does contain objects with these names, which it has re-used in confusing similar (but different) ways. See the help for that package.

Appendix A, *Classes and Methods of*

See Also

`methods` for methods of non-internal generic functions.

`S4groupGeneric` for group generics for S4 methods.

Examples

```r
require(utils)

d.fr <- data.frame(x = 1:9, y = stats::rnorm(9))
class(1 + d.fr) == "data.frame"  # add to d.f. ...

methods("Math")
methods("Ops")
methods("Summary")
methods("Complex")  # none in base R
```

Description

`grouping()` returns a permutation which rearranges its first argument such that identical values are adjacent to each other. Also returned as attributes are the group-wise partitioning and the maximum group size.

Usage

```
grouping(...)  
```

Arguments

...  

a sequence of numeric, character or logical vectors, all of the same length, or a classed R object.

Details

The function partially sorts the elements so that identical values are adjacent. NA values come last. This is guaranteed to be stable, so ties are preserved, and if the data are already grouped/sorted, the grouping is unchanged. This is useful for aggregation and is particularly fast for character vectors. Under the covers, the "radix" method of `order` is used, and the same caveats apply, including restrictions on character encodings and lack of support for long vectors (those with \(2^{31}\) or more elements). Real-valued numbers are slightly rounded to account for numerical imprecision. Like `order`, for a classed R object the grouping is based on the result of `xtfrm`. 

**Value**

An object of class "grouping", the representation of which should be considered experimental and subject to change. It is an integer vector with two attributes:

- `ends`: subscripts in the result corresponding to the last member of each group
- `maxgrpn`: the maximum group size

**See Also**

`order`, `xtfrm`.

**Examples**

```r
(ii <- grouping(x <- c(1, 1, 3:1, 1:4, 3), y <- c(9, 9:1), z <- c(2, 1:9)))
## 6 5 2 1 7 4 10 8 3 9
rbind(x, y, z)[, ii]
```

---

**Description**

`gzcon` provides a modified connection that wraps an existing connection, and decompresses reads or compresses writes through that connection. Standard gzip headers are assumed.

**Usage**

`gzcon(con, level = 6, allowNonCompressed = TRUE, text = FALSE)`

**Arguments**

- `con`: a connection.
- `level`: integer between 0 and 9, the compression level when writing.
- `allowNonCompressed`: logical. When reading, should non-compressed input be allowed?
- `text`: logical. Should the connection be text-oriented? This is distinct from the mode of the connection (must always be binary). If TRUE, `pushBack` works on the connection, otherwise `readBin` and friends apply.

**Details**

If `con` is open then the modified connection is opened. Closing the wrapper connection will also close the underlying connection.

Reading from a connection which does not supply a gzip magic header is equivalent to reading from the original connection if `allowNonCompressed` is true, otherwise an error.

Compressed output will contain embedded NUL bytes, and so `con` is not permitted to be a `textConnection` opened with `open = "w"`. Use a writable `rawConnection` to compress data into a variable.

The original connection becomes unusable: any object pointing to it will now refer to the modified connection. For this reason, the new connection needs to be closed explicitly.
hexmode

Description

Convert or print integers in hexadecimal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Usage

as.hexmode(x)

## S3 method for class 'hexmode'
as.character(x, ...)

## S3 method for class 'hexmode'

Value

An object inheriting from class "connection". This is the same connection number as supplied, but with a modified internal structure. It has binary mode.

See Also

gzfile

Examples

## Uncompress a data file from a URL
z <- gzcon(url("http://www.stats.ox.ac.uk/pub/datasets/csb/ch12.dat.gz"))
# read.table can only read from a text-mode connection.
raw <- textConnection(readLines(z))
close(z)
dat <- read.table(raw)
close(raw)
dat[1:4, ]

## gzfile and gzcon can inter-work.
## Of course here one would use gzfile, but file() can be replaced by
## any other connection generator.
zz <- gzfile("ex.gz", "w")
cat("TITLE extra line", "2 3 5 7", "," , "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzcon(file("ex.gz", "rb")))
close(zz)
unlink("ex.gz")

zz <- gzcon(file("ex2.gz", "wb"))
cat("TITLE extra line", "2 3 5 7", "," , "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzfile("ex2.gz"))
close(zz)
unlink("ex2.gz")
Hyperbolic 245

format(x, width = NULL, upper.case = FALSE, ...)

## S3 method for class 'hexmode'
print(x, ...)

Arguments

x An object, for the methods inheriting from class "hexmode".

width NULL or a positive integer specifying the minimum field width to be used, with padding by leading zeroes.

upper.case a logical indicating whether to use upper-case letters or lower-case letters (default).

... further arguments passed to or from other methods.

Details

Class "hexmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in hex.

If width = NULL (the default), the output is padded with leading zeroes to the smallest width needed for all the non-missing elements.

as.hexmode can convert integers (of type "integer" or "double") and character vectors whose elements contain only 0-9, a-f, A-F (or are NA) to class "hexmode".

There is a ! method and |, & and xor methods: these recycle their arguments to the length of the longer and then apply the operators bitwise to each element.

See Also

octmode, sprintf for other options in converting integers to hex, strtoi to convert hex strings to integers.

Examples

i <- as.hexmode("7fffffff")
i; class(i)
identical(as.integer(i), .Machine$integer.max)

hm <- as.hexmode(c(NA, 1)); hm
as.integer(hm)

Hyperbolic Functions

Description

These functions give the obvious hyperbolic functions. They respectively compute the hyperbolic cosine, sine, tangent, and their inverses, arc-cosine, arc-sine, arc-tangent (or ‘area cosine’, etc).
Usage

cosh(x)
sinh(x)
tanh(x)
acosh(x)
asinh(x)
atanh(x)

Arguments

x        a numeric or complex vector

Details

These are internal generic primitive functions: methods can be defined for them individually or via the Math group generic.

Branch cuts are consistent with the inverse trigonometric functions \texttt{asin} et seq, and agree with those defined in Abramowitz and Stegun, figure 4.7, page 86. The behaviour actually on the cuts follows the C99 standard which requires continuity coming round the endpoint in a counter-clockwise direction.

S4 methods

All are S4 generic functions: methods can be defined for them individually or via the Math group generic.

References

See Also

The logistic distribution function \texttt{plogis} is a shifted version of \texttt{tanh()} for numeric \texttt{x}.

---

\texttt{iconv} \hspace{1cm} \textit{Convert Character Vector between Encodings}

Description

This uses system facilities to convert a character vector between encodings: the ‘i’ stands for ‘internationalization’.

Usage

\texttt{iconv(x, from = "", to = "", sub = NA, mark = TRUE, toRaw = FALSE)}

\texttt{iconvlist()}
Arguments

x  A character vector, or an object to be converted to a character vector by as.character, or a list with NULL and raw elements as returned by iconv(toRaw = TRUE).

from  A character string describing the current encoding.

to  A character string describing the target encoding.

sub  character string. If not NA it is used to replace any non-convertible bytes in the input. (This would normally be a single character, but can be more.) If “byte”, the indication is “<xx>” with the hex code of the byte.

mark  logical, for expert use. Should encodings be marked?

toRaw  logical. Should a list of raw vectors be returned rather than a character vector?

Details

The names of encodings and which ones are available are platform-dependent. All R platforms support ”” (for the encoding of the current locale), ”latin1” and ”UTF-8”. Generally case is ignored when specifying an encoding.

On most platforms iconvlist provides an alphabetical list of the supported encodings. On others, the information is on the man page for iconv(5) or elsewhere in the man pages (but beware that the system command iconv may not support the same set of encodings as the C functions R calls). Unfortunately, the names are rarely supported across all platforms.

Elements of x which cannot be converted (perhaps because they are invalid or because they cannot be represented in the target encoding) will be returned as NA unless sub is specified.

Most versions of iconv will allow transliteration by appending ‘//TRANSLIT’ to the to encoding: see the examples.

Encoding ”ASCII” is accepted, and on most systems ”C” and ”POSIX” are synonyms for ASCII.

Any encoding bits (see Encoding) on elements of x are ignored: they will always be translated as if from encoding from even if declared otherwise. enc2native and enc2utf8 provide alternatives which do take declared encodings into account.

Note that implementations of iconv typically do not do much validity checking and will often mis-convert inputs which are invalid in encoding from.

Value

If toRaw = FALSE (the default), the value is a character vector of the same length and the same attributes as x (after conversion to a character vector).

If mark = TRUE (the default) the elements of the result have a declared encoding if to is ”latin1” or ”UTF-8”, or if to = ”” and the current locale’s encoding is detected as Latin-1 (or its superset CP1252 on Windows) or UTF-8.

If toRaw = TRUE, the value is a list of the same length and the same attributes as x whose elements are either NULL (if conversion fails) or a raw vector.

For iconvlist(), a character vector (typically of a few hundred elements) of known encoding names.
Implementation Details

There are three main implementations of `iconv` in use. Linux's C runtime 'glibc' contains one. Several platforms supply GNU 'libiconv', including macOS, FreeBSD and Cygwin, in some cases with additional encodings. On Windows we use a version of Yukihiro Nakadaira's 'win_iconv', which is based on Windows' codepages. (We have added many encoding names for compatibility with other systems.) All three have `iconvlist`, ignore case in encoding names and support '//TRANSLIT' (but with different results, and for 'win_iconv' currently a 'best fit' strategy is used except for to = "ASCII").

Most commercial Unixes contain an implementation of `iconv` but none we have encountered have supported the encoding names we need: the "R Installation and Administration Manual" recommends installing GNU 'libiconv' on Solaris and AIX, for example.

There are other implementations, e.g. NetBSD has used one from the Citrus project (which does not support '//TRANSLIT') and there is an older FreeBSD port ('libiconv' is usually used there): it has not been reported whether or not these work with R.

Note that you cannot rely on invalid inputs being detected, especially for to = "ASCII" where some implementations allow 8-bit characters and pass them through unchanged or with transliteration.

Some of the implementations have interesting extra encodings: for example GNU 'libiconv' allows to = "C99" to use \\uxxx escapes for non-ASCII characters.

Byte Order Marks

Most commonly known as ‘BOMs’.

Encodings using character units which are more than one byte in size can be written on a file in either big-endian or little-endian order: this applies most commonly to UCS-2, UTF-16 and UTF-32/UCS-4 encodings. Some systems will write the Unicode character U+FEFF at the beginning of a file in these encodings and perhaps also in UTF-8. In that usage the character is known as a BOM, and should be handled during input (see the ‘Encodings’ section under connection: re-encoded connections have some special handling of BOMs). The rest of this section applies when this has not been done so x starts with a BOM.

Implementations will generally interpret a BOM for from given as one of "UCS-2", "UTF-16" and "UTF-32". Implementations differ in how they treat BOMs in x in other from encodings: they may be discarded, returned as character U+FEFF or regarded as invalid.

Note

The only reasonably portable name for the ISO 8859-15 encoding, commonly known as 'Latin 9', is "latin-9": some platforms support "latin9" but GNU 'libiconv' does not.

Encoding names "utf8", "mac" and "macroman" are not portable. "utf8" is converted to "UTF-8" for from and to by `iconv`, but not for e.g. fileEncoding arguments. "macintosh" is the official (and most widely supported) name for 'Mac Roman' (https://en.wikipedia.org/wiki/Mac_OS_Roman).

# In principle, as not all systems have `iconvlist`
try(utils::head(iconvlist(), n = 50))
```
icuSetCollate

Setup Collation by ICU

Description

Controls the way collation is done by ICU (an optional part of the R build).

Usage

icuSetCollate(...)

icuGetCollate(type = c("actual", "valid"))

Arguments

... Named arguments, see ‘Details’.

type character string; can be abbreviated. Either the actual locale in use for collation or the most specific locale which would be valid.
Options, R can be built to collate character strings by ICU (http://site.icu-project.org). For such systems, icuSetCollate can be used to tune the way collation is done. On other builds calling this function does nothing, with a warning.

Possible arguments are

locale: A character string such as “da_DK” giving the language and country whose collation rules are to be used. If present, this should be the first argument.

case_first: "upper", "lower" or "default", asking for upper- or lower-case characters to be sorted first. The default is usually lower-case first, but not in all languages (not under the default settings for Danish, for example).

alternate_handling: Controls the handling of ‘variable’ characters (mainly punctuation and symbols). Possible values are "non_ignorable" (primary strength) and "shifted" (quaternary strength).

strength: Which components should be used? Possible values "primary", "secondary", "tertiary" (default), "quaternary" and "identical".

daijoubei: In a French locale the way accents affect collation is from right to left, whereas in most other locales it is from left to right. Possible values "on", "off" and "default".

normalization: Should strings be normalized? Possible values are "on" and "off" (default). This affects the collation of composite characters.

case_level: An additional level between secondary and tertiary, used to distinguish large and small Japanese Kana characters. Possible values "on" and "off" (default).

hiragana_quaternary: Possible values "on" (sort Hiragana first at quaternary level) and "off".

Only the first three are likely to be of interest except to those with a detailed understanding of collation and specialized requirements.

Some special values are accepted for locale:

"none": ICU is not used for collation: the OS’s collation services are used instead.

"ASCII": ICU is not used for collation: the C function strcmp is used instead, which should sort byte-by-byte in (unsigned) numerical order.

"default": obtains the locale from the OS as is done at the start of the session. If environment variable R_ICU_LOCALE is set to a non-empty value, its value is used rather than consulting the OS.

"", "root": the ‘root’ collation: see http://www.unicode.org/reports/tr35/tr35-collation.html#Root_Collation.

For the specifications of ‘real’ ICU locales, see http://userguide.icu-project.org/locale. Note that ICU does not report that a locale is not supported, but falls back to its idea of ‘best fit’ (which could be rather different and is reported by icuGetCollate(“actual”), often "root"). Most English locales fall back to "root" as although e.g. "en_GB" is a valid locale (at least on some platforms), it contains no special rules for collation. Note that "C" is not a supported ICU locale.

Some examples are case_level = "on", strength = "primary" to ignore accent differences and alternate_handling = "shifted" to ignore space and punctuation characters.

Initially ICU will not be used for collation if the OS is set to use the C locale for collation. Once this function is called with a value for locale, ICU will be used until it is called again with locale = "none".

All customizations are reset to the default for the locale if locale is specified: the collation engine is reset if the OS collation locate category is changed by Sys.setlocale.
identical

Value

For `icuGetCollate`, a character string describing the ICU locale in use (which may be reported as "ICU not in use"). The ‘actual’ locale may be simpler than the requested locale: for example "da" rather than "da_DK": English locales are likely to report "root".

Note

ICU is used by default wherever it is available: this include macOS, Solaris and many Linux installations. As it works internally in UTF-8, it will be most efficient in UTF-8 locales.

It is optional on Windows: if R has been built against ICU, it will only be used if environment variable `R_ICU_LOCALE` is set or once `icuSetCollate` is called to select the locale (as ICU and Windows differ in their idea of locale names). Note that `icuSetCollate(locale = "default")` should work reasonably well for R >= 3.2.0 and Windows Vista/Server 2008 and later (but finds the system default ignoring environment variables such as `LC_COLLATE`).

See Also

`Comparison`, `sort`.

`capabilities` for whether ICU is available; `extSoftVersion` for its version.

The ICU user guide chapter on collation (http://userguide.icu-project.org/collation).

Examples

```r
# These examples depend on having ICU available, and on the locale.
# As we don't know the current settings, we can only reset to the default.
if(capabilities("ICU")) {
  print(icuGetCollate())
  print(icuGetCollate("valid"))
  x <- c("Aarhus", "aarhus", "safe", "test", "Zoo")
  print(sort(x))
  icuSetCollate(case_first = "upper"); print(sort(x))
  icuSetCollate(case_first = "lower"); print(sort(x))

  # Danish collates upper-case-first and with 'aa' as a single letter
  icuSetCollate(locale = "da_DK", case_first = "default"); print(sort(x))
  # Estonian collates Z between S and T
  icuSetCollate(locale = "et_EE"); print(sort(x))
  icuSetCollate(locale = "default"); print(icuGetCollate("valid"))
}  
```

identical

Test Objects for Exact Equality

Description

The safe and reliable way to test two objects for being `exactly` equal. It returns TRUE in this case, FALSE in every other case.

Usage

```r
identical(x, y, num.eq = TRUE, single.NA = TRUE, attrib.as.set = TRUE, 
          ignore.bytecode = TRUE, ignore.environment = FALSE, 
          ignore.srcref = TRUE)
```
Arguments

x, y  any R objects.
num.eq  logical indicating if (double and complex non-NA) numbers should be compared using == (‘equal’), or by bitwise comparison. The latter (non-default) differentiates between -0 and +0.
single.NA  logical indicating if there is conceptually just one numeric NA and one NaN; single.NA = FALSE differentiates bit patterns.
attrib.as.set  logical indicating if attributes of x and y should be treated as unordered tagged pairlists (“sets”); this currently also applies to slots of S4 objects. It may well be too strict to set attrib.as.set = FALSE.
ignore.bytecode  logical indicating if byte code should be ignored when comparing closures.
ignore.environment  logical indicating if their environments should be ignored when comparing closures.
ignore.srcref  logical indicating if their "srcref" attributes should be ignored when comparing closures.

Details

A call to identical is the way to test exact equality in if and while statements, as well as in logical expressions that use && or ||. In all these applications you need to be assured of getting a single logical value.

Users often use the comparison operators, such as == or !=, in these situations. It looks natural, but it is not what these operators are designed to do in R. They return an object like the arguments. If you expected x and y to be of length 1, but it happened that one of them was not, you will not get a single FALSE. Similarly, if one of the arguments is NA, the result is also NA. In either case, the expression if(x == y).... won’t work as expected.

The function all.equal is also sometimes used to test equality this way, but was intended for something different: it allows for small differences in numeric results.

The computations in identical are also reliable and usually fast. There should never be an error. The only known way to kill identical is by having an invalid pointer at the C level, generating a memory fault. It will usually find inequality quickly. Checking equality for two large, complicated objects can take longer if the objects are identical or nearly so, but represent completely independent copies. For most applications, however, the computational cost should be negligible.

If single.NA is true, as by default, identical sees NaN as different from NA_real_, but all NaNs are equal (and all NA of the same type are equal).

Character strings are regarded as identical if they are in different marked encodings but would agree when translated to UTF-8.

If attrib.as.set is true, as by default, comparison of attributes view them as a set (and not a vector, so order is not tested).

If ignore.bytecode is true (the default), the compiled bytecode of a function (see cmpfun) will be ignored in the comparison. If it is false, functions will compare equal only if they are copies of the same compiled object (or both are uncompiled). To check whether two different compiles are equal, you should compare the results of disassemble().

You almost never want to use identical on datetimes of class "POSIXlt": not only can different times in the different time zones represent the same time and time zones have multiple names, but several of the components are optional.

Note that identical(x, y, FALSE, FALSE, FALSE, FALSE) pickily tests for exact equality.
**Value**

A single logical value, TRUE or FALSE, never NA and never anything other than a single value.

**Author(s)**

John Chambers and R Core

**References**

**See Also**

*all.equal* for descriptions of how two objects differ; *Comparison* for operators that generate elementwise comparisons. *isTRUE* is a simple wrapper based on *identical*.

**Examples**

```r
identical(1, NULL) ## FALSE -- don't try this with ==
identical(1, 1.) ## TRUE in R (both are stored as doubles)
identical(1, as.integer(1)) ## FALSE, stored as different types

x <- 1.0; y <- 0.99999999999
## how to test for object equality allowing for numeric fuzz :
(E <- all.equal(x, y))
isTRUE(E) # which is simply defined to just use
identical(TRUE, E)
## If all.equal thinks the objects are different, it returns a
## character string, and the above expression evaluates to FALSE

## even for unusual R objects :
identical(.GlobalEnv, environment())

### ------- Pickyness Flags : -----------------------------

## the infamous example:
identical(0., -0.) # TRUE, i.e. not differentiated
identical(0., -0., num.eq = FALSE)
## similar:
identical(NaN, -NaN) # TRUE
identical(NaN, -NaN, single.NA = FALSE) # differ on bit-level

### For functions ("closure"s): ----------------------------------------------
### ~~~~~~~~~

f <- function(x) x
g <- compiler::cmpfun(f)

identical(f, g) # TRUE, as bytecode is ignored by default
identical(f, g, ignore.bytecode=FALSE) # FALSE: bytecode differs

## GLM families contain several functions, some of which share an environment:
p1 <- poisson() ; p2 <- poisson()
identical(p1, p2) # FALSE
identical(p1, p2, ignore.environment=TRUE) # TRUE
```
### in interactive use, the 'keep.source' option is typically true:
op <- options(keep.source = TRUE) # and so, these have differing "srcref":
f1 <- function() {}
f2 <- function() {}
identical(f1,f2)# ignore.srcref= TRUE : TRUE
identical(f1,f2, ignore.srcref=FALSE)# FALSE
options(op) # revert to previous state

---

**identity**  
*Identity Function*

- **Description**
  A trivial identity function returning its argument.

- **Usage**
  ```
  identity(x)
  ```

- **Arguments**
  - `x`  
    An R object.

- **See Also**
  - `diag` creates diagonal matrices, including identity ones.

---

**ifelse**  
*Conditional Element Selection*

- **Description**
  `ifelse` returns a value with the same shape as `test` which is filled with elements selected from either `yes` or `no` depending on whether the element of `test` is `TRUE` or `FALSE`.

- **Usage**
  ```
  ifelse(test, yes, no)
  ```

- **Arguments**
  - `test`  
    An object which can be coerced to logical mode.
  - `yes`  
    Return values for true elements of `test`.
  - `no`  
    Return values for false elements of `test`.

- **Details**
  - If `yes` or `no` are too short, their elements are recycled. `yes` will be evaluated if and only if any element of `test` is true, and analogously for `no`.
  - Missing values in `test` give missing values in the result.
Value
A vector of the same length and attributes (including dimensions and "class") as test and data values from the values of yes or no. The mode of the answer will be coerced from logical to accommodate first any values taken from yes and then any values taken from no.

Warning
The mode of the result may depend on the value of test (see the examples), and the class attribute (see oldClass) of the result is taken from test and may be inappropriate for the values selected from yes and no.
Sometimes it is better to use a construction such as

\[(tmp <- yes; tmp[!test] <- no[!test]; tmp)\]

, possibly extended to handle missing values in test.

Further note that if(test) yes else no is much more efficient and often much preferable to ifelse(test, yes, no) whenever test is a simple true/false result, i.e., when length(test) == 1.
The srcRef attribute of functions is handled specially: if test is a simple true result and yes evaluates to a function with srcRef attribute, ifelse returns yes including its attribute (the same applies to a false test and no argument). This functionality is only for backwards compatibility, the form if(test) yes else no should be used whenever yes and no are functions.

References

See Also
if.

Examples
x <- c(6:-4)
sqrt(x) # gives warning
sqrt(ifelse(x >= 0, x, NA)) # no warning

## Note: the following also gives the warning !
ifelse(x >= 0, sqrt(x), NA)

## ifelse() strips attributes
## This is important when working with Dates and factors
x <- seq(as.Date("2000-02-29"), as.Date("2004-10-04"), by = "1 month")
## has many "yyyy-mm-29", but a few "yyyy-03-01" in the non-leap years
y <- ifelse(as.POSIXlt(x)$mday == 29, x, NA)
head(y) # not what you expected ... ==> need restore the class attribute:
class(y) <- class(x)
y
## This is a (not atypical) case where it is better *not* to use ifelse(),
## but rather the more efficient and still clear:
y2 <- x
y2[as.POSIXlt(x)$mday != 29] <- NA
## which gives the same as ifelse()+class() hack:
stopifnot(identical(y2, y))

## example of different return modes (and 'test' alone determining length):
yes <- 1:3
no <- pi^(1:4)
utils::str( ifelse(NA, yes, no) ) # logical, length 1
utils::str( ifelse(TRUE, yes, no) ) # integer, length 1
utils::str( ifelse(FALSE, yes, no) ) # double, length 1

---

### Description

Creates or tests for objects of type “integer”.

### Usage

- `integer(length = 0)`
- `as.integer(x, ...)`
- `is.integer(x)`

### Arguments

- **length**: A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
- **x**: object to be coerced or tested.
- **...**: further arguments passed to or from other methods.

### Details

Integer vectors exist so that data can be passed to C or Fortran code which expects them, and so that (small) integer data can be represented exactly and compactly.

Note that current implementations of \( R \) use 32-bit integers for integer vectors, so the range of representable integers is restricted to about \( \pm 2 \times 10^9 \): **doubles** can hold much larger integers exactly.

### Value

- `integer` creates a integer vector of the specified length. Each element of the vector is equal to 0.
- `as.integer` attempts to coerce its argument to be of integer type. The answer will be NA unless the coercion succeeds. Real values larger in modulus than the largest integer are coerced to NA (unlike S which gives the most extreme integer of the same sign). Non-integral numeric values are truncated towards zero (i.e., `as.integer(x)` equals `trunc(x)` there), and imaginary parts of complex numbers are discarded (with a warning). Character strings containing optional whitespace followed by either a decimal representation or a hexadecimal representation (starting with `0x` or `0X`) can be converted, as well as any allowed by the platform for real numbers. Like `as.vector` it strips attributes including names. (To ensure that an object `x` is of integer type without stripping attributes, use `storage.mode(x) <- "integer"`.)
- `is.integer` returns TRUE or FALSE depending on whether its argument is of integer type or not, unless it is a factor when it returns FALSE.
Note

is.integer(x) does not test if x contains integer numbers! For that, use round, as in the function is.wholenumber(x) in the examples.

References

See Also

numeric, storage.mode.

round (and ceiling and floor on that help page) to convert to integral values.

Examples

## as.integer() truncates:

x <- pi * c(-1:1, 10)
as.integer(x)

is.integer(1) # is FALSE !

is.wholenumber <-
  function(x, tol = .Machine$double.eps*0.5) abs(x - round(x)) < tol
is.wholenumber(1) # is TRUE
(x <- seq(1, 5, by = 0.5) )
is.wholenumber( x ) #--> TRUE FALSE TRUE ...

interaction

Compute Factor Interactions

Description

interaction computes a factor which represents the interaction of the given factors. The result of interaction is always unordered.

Usage

interaction(..., drop = FALSE, sep = ".", lex.order = FALSE)

Arguments

... the factors for which interaction is to be computed, or a single list giving those factors.
drop if drop is TRUE, unused factor levels are dropped from the result. The default is to retain all factor levels.
sep string to construct the new level labels by joining the constituent ones.
lex.order logical indicating if the order of factor concatenation should be lexically ordered.
interactive

Value
A factor which represents the interaction of the given factors. The levels are labelled as the levels of the individual factors joined by sep which is \( \cdot \) by default.

By default, when `lex.order = FALSE`, the levels are ordered so the level of the first factor varies fastest, then the second and so on. This is the reverse of lexicographic ordering (which you can get by `lex.order = TRUE`), and differs from `:`. (It is done this way for compatibility with S.)

References

See Also
`factor`; `f:g` is similar to `interaction(f, g, sep = ":")` when \( f \) and \( g \) are factors.

Examples
```r
a <- gl(2, 4, 8)
b <- gl(2, 2, 8, labels = c("ctrl", "treat"))
s <- gl(2, 1, 8, labels = c("M", "F"))
interaction(a, b)
interaction(a, b, s, sep = ":")
stopifnot(identical(a:s, interaction(a, s, sep = ":", lex.order = TRUE)),
          identical(a:s:b, interaction(a, s, b, sep = ":", lex.order = TRUE)))
```

interactive \hspace{1cm} Is R Running Interactively?

Description
Return `TRUE` when R is being used interactively and `FALSE` otherwise.

Usage
`interactive()`

Details
An interactive R session is one in which it is assumed that there is a human operator to interact with, so for example R can prompt for corrections to incorrect input or ask what to do next or if it is OK to move to the next plot.

GUI consoles will arrange to start R in an interactive session. When R is run in a terminal (via `Rterm.exe` on Windows), it assumes that it is interactive if `stdin` is connected to a (pseudo-)terminal and not if `stdin` is redirected to a file or pipe. Command-line options `--interactive` (Unix) and `--ess` (Windows, `Rterm.exe`) override the default assumption. (On a Unix-alike, whether the readline command-line editor is used is `not` overridden by `--interactive`.)

Embedded uses of R can set a session to be interactive or not.

Internally, whether a session is interactive determines
how some errors are handled and reported, e.g. see `stop` and `options("showWarnCalls")`.

- whether one of `--save`, `--no-save` or `--vanilla` is required, and if R ever asks whether to save the workspace.

- the choice of default graphics device launched when needed and by `dev.new`: see `options("device")`

- whether graphics devices ever ask for confirmation of a new page.

In addition, R’s own R code makes use of `interactive()`: for example `help`, `debugger` and `install.packages` do.

**Note**

This is a *primitive* function.

**See Also**

`source`, `.First`

**Examples**

`.First <- function() if(interactive()) x11()`
Many R-internal functions are generic and allow methods to be written for.

The following primitive and internal functions are generic, i.e., you can write methods for them:

- `.[`, `.$`, `[<-`, `[[<-`, `$<-`, `length`, `length<-`, `dimnames`, `dimnames<-`, `dim`, `dim<-`, `names`, `names<-`, `levels<-`, `c`, `unlist`, `cbind`, `rbind`, `as.character`, `as.complex`, `as.double`, `as.integer`, `as.logical`, `as.raw`, `as.vector`, `is.array`, `is.matrix`, `is.na`, `is.nan`, `is.numeric`, `rep`, `seq.int` (which dispatches methods for "seq") and `xtfrm`

In addition, `is.name` is a synonym for `is.symbol` and dispatches methods for the latter. Similarly, `as.numeric` is a synonym for `as.double` and dispatches methods for the latter, i.e., S3 methods are for `as.double`, whereas S4 methods are to be written for `as.numeric`.

Note that all of the group generic functions are also internal/primitive and allow methods to be written for them.

`.S3PrimitiveGenerics` is a character vector listing the primitives which are internal generic and not group generic. Currently `as.vector`, `cbind`, `rbind` and `unlist` are the internal non-primitive functions which are internally generic.

For efficiency, internal dispatch only occurs on objects, that is those for which `is.object` returns true.

See Also

- `methods` for the methods which are available.

### invisible

**Description**

Return a (temporarily) invisible copy of an object.

**Usage**

```r
invisible(x)
```

**Arguments**

- `x` an arbitrary R object.
Details

This function can be useful when it is desired to have functions return values which can be assigned, but which do not print when they are not assigned.

This is a primitive function.

References

See Also

`withVisible`, `return`, `function`.

Examples

# These functions both return their argument
f1 <- function(x) x
f2 <- function(x) invisible(x)
f1(1) # prints
f2(1) # does not

is.finite

Description

`is.finite` and `is.infinite` return a vector of the same length as `x`, indicating which elements are finite (not infinite and not missing) or infinite.

`Inf` and `-Inf` are positive and negative infinity whereas `NaN` means ‘Not a Number’. (These apply to numeric values and real and imaginary parts of complex values but not to values of integer vectors.) `Inf` and `NaN` are reserved words in the R language.

Usage

`is.finite(x)`
`is.infinite(x)`
`is.nan(x)`

`Inf`
`NaN`

Arguments

`x`  
R object to be tested: the default methods handle atomic vectors.
Details

`is.finite` returns a vector of the same length as `x` the jth element of which is `TRUE` if `x[j]` is finite (i.e., it is not one of the values `NA`, `NaN`, `Inf` or `-Inf`) and `FALSE` otherwise. Complex numbers are finite if both the real and imaginary parts are.

`is.infinite` returns a vector of the same length as `x` the jth element of which is `TRUE` if `x[j]` is infinite (i.e., equal to one of `Inf` or `-Inf`) and `FALSE` otherwise. This will be false unless `x` is numeric or complex. Complex numbers are infinite if either the real or the imaginary part is.

`is.nan` tests if a numeric value is `NaN`. Do not test equality to `NaN`, or even use `identical`, since systems typically have many different `NaN` values. One of these is used for the numeric missing value `NA`, and `is.nan` is false for that value. A complex number is regarded as `NaN` if either the real or imaginary part is `NaN` but not `NA`. All elements of logical, integer and raw vectors are considered not to be `NaN`.

All three functions accept `NULL` as input and return a length zero result. The default methods accept character and raw vectors, and return `FALSE` for all entries. Prior to R version 2.14.0 they accepted all input, returning `FALSE` for most non-numeric values; cases which are not atomic vectors are now signalled as errors.

All three functions are generic: you can write methods to handle specific classes of objects, see `InternalMethods`.

Value

A logical vector of the same length as `x`: `dim`, `dimnames` and `names` attributes are preserved.

Note

In R, basically all mathematical functions (including basic `Arithmetic`), are supposed to work properly with `+/- Inf` and `NaN` as input or output.

The basic rule should be that calls and relations with `Inf`s really are statements with a proper mathematical `limit`.

Computations involving `NaN` will return `NaN` or perhaps `NA`: which of those two is not guaranteed and may depend on the R platform (since compilers may re-order computations).

References

The IEC 60559 standard, also known as the ANSI/IEEE 754 Floating-Point Standard.

https://en.wikipedia.org/wiki/NaN.

The C99 function `isfinite` is used for `is.finite`.

See Also

`NA`, `Not Available` which is not a number as well, however usually used for missing values and applies to many modes, not just numeric and complex.
is.function

Examples

\[
\frac{\pi}{0} \# = \text{Inf} \quad \text{a non-zero number divided by zero creates infinity}
\]
\[
\frac{0}{0} \# = \text{NaN}
\]
\[
\frac{1}{0} + \frac{1}{0} \# \text{ Inf}
\]
\[
\frac{1}{0} - \frac{1}{0} \# \text{ NaN}
\]

\[
\text{stopifnot(}
\quad 1/0 == \text{Inf},
\quad 1/\text{Inf} == 0
\text{)}
\]
\[
\sin(\text{Inf})
\]
\[
\cos(\text{Inf})
\]
\[
\tan(\text{Inf})
\]

is.function

Is an Object of Type (Primitive) Function?

Description

Checks whether its argument is a (primitive) function.

Usage

is.function(x)

is.primitive(x)

Arguments

x

an R object.

Details

is.primitive(x) tests if x is a primitive function (either a "builtin" or "special" as described for typeof)? It is a primitive function.

Value

TRUE if x is a (primitive) function, and FALSE otherwise.

Examples

is.function(1) \# FALSE

is.function(is.primitive) \# TRUE: it is a function, but . . .

is.primitive(is.primitive) \# FALSE: it's not a primitive one, whereas

is.primitive(is.function) \# TRUE: that one *is*
is.language  Is an Object a Language Object?

Description

is.language returns TRUE if x is a variable name, a call, or an expression.

Usage

is.language(x)

Arguments

x  object to be tested.

Note

A name is also known as 'symbol', from its type (typeof), see is.symbol.

This is a primitive function.

References

Examples

ll <- list(a = expression(x^2 - 2*x + 1), b = as.name("Jim"), c = as.expression(exp(1)), d = call("sin", pi))
sapply(ll, typeof)
sapply(ll, mode)
stopifnot(sapply(ll, is.language))

is.object  Is an Object 'internally classed'?

Description

A function rather for internal use. It returns TRUE if the object x has the R internal OBJECT bit set, and FALSE otherwise. The OBJECT bit is set when a "class" attribute is added and removed when that attribute is removed, so this is a very efficient way to check if an object has a class attribute. (S4 objects always should.)

Usage

is.object(x)

Arguments

x  object to be tested.
is.R

Note

This is a primitive function.

See Also

class, and methods.
isS4.

Examples

is.object(1) # FALSE
is.object(as.factor(1:3)) # TRUE

Description

Test if running under R.

Usage

is.R()

Details

The function has been written such as to correctly run in all versions of R, S and S-PLUS. In order for code to be runnable in both R and S dialects previous to S-PLUS 8.0, your code must either define is.R or use it as

```r
if (exists("is.R") && is.function(is.R) && is.R()) {
  ## R-specific code
} else {
  ## S-version of code
}
```

Value

is.R returns TRUE if we are using R and FALSE otherwise.

See Also

R.version, system.

Examples

```r
x <- stats::runif(20); small <- x < 0.4
## In the early years of R, 'which()' only existed in R:
if(is.R()) which(small) else seq(along = small)[small]
```
is.recursive

Is an Object Atomic or Recursive?

Description

is.atomic returns TRUE if x is of an atomic type (or NULL) and FALSE otherwise.
is.recursive returns TRUE if x has a recursive (list-like) structure and FALSE otherwise.

Usage

is.atomic(x)
is.recursive(x)

Arguments

x object to be tested.

Details

is.atomic is true for the atomic types ("logical", "integer", "numeric", "complex", "character" and "raw") and NULL.

Most types of objects are regarded as recursive. Exceptions are the atomic types, NULL, symbols (as given by as.name), S4 objects with slots, external pointers, and—rarely visible from R—weak references and byte code, see typeof.

It is common to call the atomic types ‘atomic vectors’, but note that is.vector imposes further restrictions: an object can be atomic but not a vector (in that sense).

These are primitive functions.

References

See Also

is.list, is.language, etc, and the demo("is.things").

Examples

require(stats)
is.a.r <- function(x) c(is.atomic(x), is.recursive(x))

is.a.r(c(a = 1, b = 3))  # TRUE FALSE
is.a.r(list())          # FALSE TRUE - a list is a list
is.a.r(list(2))         # FALSE TRUE
is.a.r(lm)              # FALSE TRUE
is.a.r(y ~ x)           # FALSE TRUE
is.a.r(expression(x+1)) # FALSE TRUE
is.a.r(quote(exp))      # FALSE FALSE
is.single  

Is an Object of Single Precision Type?

Description

is.single reports an error. There are no single precision values in R.

Usage

is.single(x)

Arguments

x  
object to be tested.

References

is.unsorted  

Test if an Object is Not Sorted

Description

Test if an object is not sorted (in increasing order), without the cost of sorting it.

Usage

is.unsorted(x, na.rm = FALSE, strictly = FALSE)

Arguments

x  
an R object with a class or a numeric, complex, character, logical or raw vector.

na.rm  
logical. Should missing values be removed before checking?

strictly  
logical indicating if the check should be for strictly increasing values.

Value

A length-one logical value. All objects of length 0 or 1 are sorted. Otherwise, the result will be NA except for atomic vectors and objects with an S3 class (where the >= or > method is used to compare x[i] with x[i-1] for i in 2:length(x)) or with an S4 class where you have to provide a method for is.unsorted().

Note

This function is designed for objects with one-dimensional indices, as described above. Data frames, matrices and other arrays may give surprising results.

See Also

sort, order.
Description

Convenience wrappers to create date-times from numeric representations.

Usage

ISOdatetime(year, month, day, hour, min, sec, tz = "")
ISOdate(year, month, day, hour = 12, min = 0, sec = 0, tz = "GMT")

Arguments

year, month, day numerical values to specify a day.
hour, min, sec numerical values for a time within a day. Fractional seconds are allowed.
tz A time zone specification to be used for the conversion. "" is the current time zone and "GMT" is UTC. Invalid values are most commonly treated as UTC, on some platforms with a warning.

Details

ISOdatetime and ISOdate are convenience wrappers for strptime that differ only in their defaults and that ISOdate sets UTC as the time zone. For dates without times it would normally be better to use the "Date" class.

The main arguments will be recycled using the usual recycling rules.

Because these make use of strftime, only years in the range 0:9999 are accepted.

Value

An object of class "POSIXct".

See Also

DateTimeClasses for details of the date-time classes; strftime for conversions from character strings.

isS4

Test for an S4 object

Description

Tests whether the object is an instance of an S4 class.
Usage

isS4(object)

asS4(object, flag = TRUE, complete = TRUE)
asS3(object, flag = TRUE, complete = TRUE)

Arguments

object Any R object.
flag Optional, logical: indicate direction of conversion.
complete Optional, logical: whether conversion to S3 is completed. Not usually needed, but see the details section.

Details

Note that isS4 does not rely on the methods package, so in particular it can be used to detect the need to require that package.
asS3 uses the value of complete to control whether an attempt is made to transform object into a valid object of the implied S3 class. If complete is TRUE, then an object from an S4 class extending an S3 class will be transformed into an S3 object with the corresponding S3 class (see S3Part). This includes classes extending the pseudo-classes array and matrix: such objects will have their class attribute set to NULL.
isS4 is primitive.

Value

isS4 always returns TRUE or FALSE according to whether the internal flag marking an S4 object has been turned on for this object.
asS4 and asS3 will turn this flag on or off, and asS3 will set the class from the objects .S3Class slot if one exists. Note that asS3 will not turn the object into an S3 object unless there is a valid conversion; that is, an object of type other than "S4" for which the S4 object is an extension, unless argument complete is FALSE.

See Also

is.object for a more general test; Introduction for general information on S4; Classes_Details for more on S4 class definitions.

Examples

isS4(pi) # FALSE
isS4(getClass("MethodDefinition")) # TRUE
Description

Generic function to test if object is symmetric or not. Currently only a matrix method is implemented, where a complex matrix \( Z \) must be “Hermitian” for \( \text{isSymmetric}(Z) \) to be true.

Usage

\[
\text{isSymmetric}(\text{object}, \ldots)
\]

## S3 method for class 'matrix'

\[
\text{isSymmetric}(\text{object}, \text{tol} = 100 \times \text{.Machine}$\text{double.eps}$, \\
\quad \text{tol1} = 8 \times \text{tol}, \ldots)
\]

Arguments

- **object**: any R object; a matrix for the matrix method.
- **tol**: numeric scalar \( \geq 0 \). Smaller differences are not considered, see `all.equal.numeric`.
- **tol1**: numeric scalar \( \geq 0 \). `isSymmetric.matrix()` 'pre-tests' the first and last few rows for fast detection of 'obviously' asymmetric cases with this tolerance. Setting it to length zero will skip the pre-tests.
- **...**: further arguments passed to methods; the matrix method passes these to `all.equal`.

Details

The matrix method is used inside `eigen` by default to test symmetry of matrices up to rounding error, using `all.equal`. It might not be appropriate in all situations.

Note that a matrix \( m \) is only symmetric if its rownames and colnames are identical. Consider using `unname(m)`.

Value

logical indicating if object is symmetric or not.

See Also

- `eigen` which calls `isSymmetric` when its symmetric argument is missing.

Examples

\[
\text{isSymmetric(D3 <- \text{diag}(3)) \# \rightarrow TRUE}
\]

\[
D3[2, 1] <- 1e-100
D3
\]

\[
\text{isSymmetric(D3) \# TRUE}
\]

\[
\text{isSymmetric(D3, tol = 0) \# FALSE for zero-tolerance}
\]

## Complex Matrices - Hermitian or not
jitter

Description

Add a small amount of noise to a numeric vector.

Usage

jitter(x, factor = 1, amount = NULL)

Arguments

x numeric vector to which jitter should be added.
factor numeric.
amount numeric; if positive, used as amount (see below), otherwise, if = 0 the default is factor * z/50. Default (NULL): factor * d/5 where d is about the smallest difference between x values.

Details

The result, say r, is r <- x + runif(n, -a, a) where n <- length(x) and a is the amount argument (if specified).
Let z <- max(x) - min(x) (assuming the usual case). The amount a to be added is either provided as positive argument amount or otherwise computed from z, as follows:
If amount == 0, we set a <- factor * z/50 (same as S).
If amount is NULL (default), we set a <- factor * d/5 where d is the smallest difference between adjacent unique (apart from fuzz) x values.

Value

jitter(x, ...) returns a numeric of the same length as x, but with an amount of noise added in order to break ties.

Author(s)

Werner Stahel and Martin Maechler, ETH Zurich

References

See Also

rug which you may want to combine with jitter.

Examples

```r
round(jitter(c(rep(1, 3), rep(1.2, 4), rep(3, 3))), 3)
## These two 'fail' with S-plus 3.x:
  jitter(rep(0, 7))
  jitter(rep(10000, 5))
```

kappa

Compute or Estimate the Condition Number of a Matrix

Description

The condition number of a regular (square) matrix is the product of the norm of the matrix and the norm of its inverse (or pseudo-inverse), and hence depends on the kind of matrix-norm.

`kappa()` computes by default (an estimate of) the 2-norm condition number of a matrix or of the `R` matrix of a `QR` decomposition, perhaps of a linear fit. The 2-norm condition number can be shown to be the ratio of the largest to the smallest non-zero singular value of the matrix.

`rcond()` computes an approximation of the reciprocal condition number, see the details.

Usage

```r
kappa(z, ...)
## Default S3 method:
  kappa(z, exact = FALSE, 
         norm = NULL, method = c("qr", "direct"), ...)
## S3 method for class 'lm'
  kappa(z, ...)
## S3 method for class 'qr'
  kappa(z, ...)
```

```
.kappa_tri(z, exact = FALSE, LINPACK = TRUE, norm = NULL, ...)
```

```r
rcond(x, norm = c("O","I","1"), triangular = FALSE, ...)
```

Arguments

```r
z, x A matrix or a the result of `qr` or a fit from a class inheriting from "lm".
exact logical. Should the result be exact?
norm character string, specifying the matrix norm with respect to which the condition number is to be computed, see also `norm`. For `rcond`, the default is "O", meaning the One- or 1-norm. The (currently only) other possible value is "I" for the infinity norm.
method a partially matched character string specifying the method to be used; "qr" is the default for back-compatibility, mainly.
triangular logical. If true, the matrix used is just the lower triangular part of `z`.
```
Details

For kappa(), if exact = FALSE (the default) the 2-norm condition number is estimated by a cheap approximation. However, the exact calculation (via svd) is also likely to be quick enough.

Note that the 1- and Inf-norm condition numbers are much faster to calculate, and rcond() computes these reciprocal condition numbers, also for complex matrices, using standard Lapack routines.

kappa and rcond are different interfaces to partly identical functionality.

.kappa_tri is an internal function called by kappa.qr and kappa.default.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The condition number, kappa, or an approximation if exact = FALSE.

Author(s)

The design was inspired by (but differs considerably from) the S function of the same name described in Chambers (1992).

norm; svd for the singular value decomposition and qr for the QR one.

Examples

kappa(x1 <- cbind(1, 1:10)) # 15.71
kappa(x1, exact = TRUE)     # 13.68
kappa(x2 <- cbind(x1, 2:11)) # high! [x2 is singular!]

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "*") }
sv9 <- svd(h9 <- hilbert(9))$ d
kappa(h9)  # pretty high!
kappa(h9, exact = TRUE) == max(sv9) / min(sv9)
kappa(h9, exact = TRUE) / kappa(h9)  # 0.677 (i.e., rel.error = 32%)

---

kronecker

**Kronecker Products on Arrays**

**Description**

Computes the generalised kronecker product of two arrays, X and Y.

**Usage**

```r
kronecker(X, Y, FUN = "*", make.dimnames = FALSE, ...)
X %x% Y
```

**Arguments**

- **X**: A vector or array.
- **Y**: A vector or array.
- **FUN**: a function; it may be a quoted string.
- **make.dimnames**: Provide dimnames that are the product of the dimnames of X and Y.
- **...**: optional arguments to be passed to FUN.

**Details**

If X and Y do not have the same number of dimensions, the smaller array is padded with dimensions of size one. The returned array comprises submatrices constructed by taking X one term at a time and expanding that term as `FUN(x, Y, ...)`. %x% is an alias for `kronecker` (where FUN is hardwired to "*").

**Value**

An array A with dimensions `dim(X) * dim(Y)`.

**Author(s)**

Jonathan Rougier

**References**

**See Also**

outer, on which kronecker is built and %x% for usual matrix multiplication.
Examples

# simple scalar multiplication
( M <- matrix(1:6, ncol = 2) )
kronecker(4, M)
# Block diagonal matrix:
kronecker(diag(1, 3), M)

# ask for dimnames
fred <- matrix(1:12, 3, 4, dimnames = list(LETTERS[1:3], LETTERS[4:7]))
bill <- c("happy" = 100, "sad" = 1000)
kronecker(fred, bill, make.dimnames = TRUE)

bill <- outer(bill, c("cat" = 3, "dog" = 4))
kronecker(fred, bill, make.dimnames = TRUE)

Description

Report on localization information.

Usage

l10n_info()

Value

A list with three logical components:

MBCS     If a multi-byte character set in use?
UTF-8    Is this a UTF-8 locale?
Latin-1  Is this a Latin-1 locale?

See Also

Sys.getlocale, localeconv

Examples

l10n_info()
labels

Find Labels from Object

Description
Find a suitable set of labels from an object for use in printing or plotting, for example. A generic function.

Usage
labels(object, ...)

Arguments
object Any R object: the function is generic.
... further arguments passed to or from other methods.

Value
A character vector or list of such vectors. For a vector the results is the names or \( \text{seq\_along}(x) \) and for a data frame or array it is the dimnames (with \text{NULL} expanded to \( \text{seq\_len}(d[i]) \)).

References

lapply
Apply a Function over a List or Vector

Description
\text{lapply} returns a list of the same length as \( X \), each element of which is the result of applying \text{FUN} to the corresponding element of \( X \).

\text{sapply} is a user-friendly version and wrapper of \text{lapply} by default returning a vector, matrix or, if \text{simplify} = “array”, an array if appropriate, by applying \text{simplify2array}(\).
\text{sapply}(x, f, \text{simplify} = \text{FALSE}, \text{USE.NAMES} = \text{FALSE}) is the same as \text{lapply}(x, f).

\text{vapply} is similar to \text{sapply}, but has a pre-specified type of return value, so it can be safer (and sometimes faster) to use.

\text{replicate} is a wrapper for the common use of \text{sapply} for repeated evaluation of an expression (which will usually involve random number generation).

\text{simplify2array}() is the utility called from \text{sapply}() when \text{simplify} is not false and is similarly called from \text{mapply}().
**lapply**

**Usage**

- `lapply(X, FUN, ...)`
- `sapply(X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)`
- `vapply(X, FUN, FUN.VALUE, ..., USE.NAMES = TRUE)`
- `replicate(n, expr, simplify = "array")`
- `simplify2array(x, higher = TRUE)`

**Arguments**

- **X** a vector (atomic or list) or an expression object. Other objects (including classed objects) will be coerced by `base::as.list`.
- **FUN** the function to be applied to each element of X: see ‘Details’. In the case of functions like +, %*%, the function name must be backquoted or quoted.
- **...** optional arguments to FUN.
- **simplify** logical or character string: should the result be simplified to a vector, matrix or higher dimensional array if possible? For `sapply` it must be named and not abbreviated. The default value, `TRUE`, returns a vector or matrix if appropriate, whereas if `simplify = "array"` the result may be an array of “rank” (\(=\text{length}(\text{dim}(.))\)) one higher than the result of `FUN(X[[i]])`.
- **USE.NAMES** logical; if `TRUE` and if X is character, use X as names for the result unless it had names already. Since this argument follows ... its name cannot be abbreviated.
- **FUN.VALUE** a (generalized) vector; a template for the return value from FUN. See ‘Details’.
- **n** integer: the number of replications.
- **expr** the expression (a language object, usually a call) to evaluate repeatedly.
- **x** a list, typically returned from `lapply()`.
- **higher** logical; if true, `simplify2array()` will produce a (“higher rank”) array when appropriate, whereas `higher = FALSE` would return a matrix (or vector) only. These two cases correspond to `sapply(*, simplify = "array")` or `simplify = TRUE`, respectively.

**Details**

FUN is found by a call to `match.fun` and typically is specified as a function or a symbol (e.g., a backquoted name) or a character string specifying a function to be searched for from the environment of the call to `lapply`.

Function FUN must be able to accept as input any of the elements of X. If the latter is an atomic vector, FUN will always be passed a length-one vector of the same type as X.

Arguments in ... cannot have the same name as any of the other arguments, and care may be needed to avoid partial matching to FUN. In general-purpose code it is good practice to name the first two arguments X and FUN if ... is passed through: this both avoids partial matching to FUN and ensures that a sensible error message is given if arguments named X or FUN are passed through . . . .

Simplification in `sapply` is only attempted if X has length greater than zero and if the return values from all elements of X are all of the same (positive) length. If the common length is one the result is a vector, and if greater than one is a matrix with a column corresponding to each element of X.
Simplification is always done in \texttt{vapply}. This function checks that all values of \texttt{FUN} are compatible with the \texttt{FUN.VALUE}, in that they must have the same length and type. (Types may be promoted to a higher type within the ordering logical $<$ integer $<$ double $<$ complex, but not demoted.)

Users of S4 classes should pass a list to \texttt{lapply} and \texttt{vapply}: the internal coercion is done by the \texttt{as.list} in the base namespace and not one defined by a user (e.g., by setting S4 methods on the base function).

\texttt{lapply} and \texttt{vapply} are \textit{primitive} functions.

\textbf{Value}

For \texttt{lapply}, \texttt{sapply(simplify = FALSE)} and \texttt{replicate(simplify = FALSE)}, a list.

For \texttt{sapply(simplify = TRUE)} and \texttt{replicate(simplify = TRUE)}: if \( X \) has length zero or \( n = 0 \), an empty list. Otherwise an atomic vector or matrix or list of the same length as \( X \) (of length \( n \) for \texttt{replicate}). If simplification occurs, the output type is determined from the highest type of the return values in the hierarchy \texttt{NULL $<$ raw $<$ logical $<$ integer $<$ double $<$ complex $<$ character $<$ list $<$ expression}, after coercion of pairlists to lists.

\texttt{vapply} returns a vector or array of type matching the \texttt{FUN.VALUE}. If \( \text{length(FUN.VALUE)} = 1 \) a vector of the same length as \( X \) is returned, otherwise an array. If \texttt{FUN.VALUE} is not an \texttt{array}, the result is a matrix with \texttt{length(FUN.VALUE)} rows and \texttt{length(X)} columns, otherwise an array \( a \) with \texttt{dim(a) = c(dim(FUN.VALUE), length(X))}.

The (Dim)names of the array value are taken from the \texttt{FUN.VALUE} if it is named, otherwise from the result of the first function call. Column names of the matrix or more generally the names of the last dimension of the array value or names of the vector value are set from \( X \) as in \texttt{sapply}.

\textbf{Note}

\texttt{sapply(*, simplify = FALSE, USE.NAMES = FALSE)} is equivalent to \texttt{lapply(*)}.

For historical reasons, the calls created by \texttt{lapply} are unevaluated, and code has been written (e.g., \texttt{bquote}) that relies on this. This means that the recorded call is always of the form \texttt{FUN(X[[1]], \ldots)}, with \texttt{i} replaced by the current (integer or double) index. This is not normally a problem, but it can be if \texttt{FUN} uses \texttt{sys.call} or \texttt{match.call} or if it is a primitive function that makes use of the call. This means that it is often safer to call primitive functions with a wrapper, so that e.g. \texttt{lapply(ll, function(x) is.numeric(x))} is required to ensure that method dispatch for \texttt{is.numeric} occurs correctly.

If \texttt{expr} is a function call, be aware of assumptions about where it is evaluated, and in particular what \texttt{\ldots} might refer to. You can pass additional named arguments to a function call as additional named arguments to \texttt{replicate}: see ‘Examples’.

\textbf{References}

\textbf{See Also}

\texttt{apply, tapply, mapply} for applying a function to \textbf{multiple} arguments, and \texttt{rapply} for a recursive version of \texttt{lapply()}, \texttt{eapply} for applying a function to each entry in an \texttt{environment}. 
Examples

```r
require(stats); require(graphics)

x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE, FALSE, FALSE, TRUE))
# compute the list mean for each list element
lapply(x, mean)
# median and quartiles for each list element
lapply(x, quantile, probs = 1:3/4)
sapply(x, quantile)
i39 <- sapply(3:9, seq) # list of vectors
sapply(i39, fivenum)
vapply(i39, fivenum,
      c(Min. = 0, "1st Qu." = 0, Median = 0, "3rd Qu." = 0, Max. = 0))

## sapply(*, "array") -- artificial example
(v <- structure(10*rep(5:8), names = LETTERS[1:4]))
f2 <- function(x, y) outer(rep(x, length.out = 3), y)
(a2 <- sapply(v, f2, y = 2*(1:5), simplify = "array"))
a.2 <- vapply(v, f2, outer(1:3, 1:5), y = 2*(1:5))
stopifnot(dim(a2) == c(3,5,4), all.equal(a2, a.2),
      identical(dimnames(a2), list(NULL,NULL,LETTERS[1:4])))

hist(replicate(100, mean(rexp(10))))
```

## Description

The value of the internal evaluation of a top-level R expression is always assigned to `.Last.value` (in package:base) before further processing (e.g., printing).

### Usage

`.Last.value`

### Details

The value of a top-level assignment is put in `.Last.value`, unlike S.

Do not assign to `.Last.value` in the workspace, because this will always mask the object of the same name in package:base.

### See Also

`eval`
## Examples

```r
## These will not work correctly from example(),
## but they will in make check or if pasted in,
## as example() does not run them at the top level
gamma(1:15)  # think of some intensive calculation...
fac14 <- .Last.value  # keep them

library("splines")  # returns invisibly
.Last.value  # shows what library(.) above returned
```

---

### Description

Report the name of the shared object file with LAPACK implementation in use.

### Usage

```r
La_library()
```

### Value

A character vector of length one ("" when the name is not known). The value can be used as an indication of which LAPACK implementation is in use. Typically, the R version of LAPACK will appear as libRlapack.so (libRlapack.dylib), depending on how R was built. Note that libRlapack.so (libRlapack.dylib) may also be shown for an external LAPACK implementation that had been copied, hard-linked or renamed by the system administrator. Otherwise, the shared object file will be given and its path/name may indicate the vendor/version. The detection does not work on Windows.

### See Also

- [extSoftVersion](https://CRAN.R-project.org/package=extSoftVersion) for versions of other third-party software including BLAS.
- [La_version](https://CRAN.R-project.org/package=La_version) for the version of LAPACK in use.

### Examples

```r
La_library()
```
La_version

LAPACK Version

Description
Report the version of LAPACK in use.

Usage
La_version()

Value
A character vector of length one.

See Also
extSoftVersion for versions of other third-party software.
La_library for binary/executable file with LAPACK in use.

Examples
La_version()

length

Length of an Object

Description
Get or set the length of vectors (including lists) and factors, and of any other R object for which a method has been defined.

Usage
length(x)
length(x) <- value

Arguments
x an R object. For replacement, a vector or factor.
value a non-negative integer or double (which will be rounded down).

Details
Both functions are generic: you can write methods to handle specific classes of objects, see InternalMethods. length<- has a “factor” method.

The replacement form can be used to reset the length of a vector. If a vector is shortened, extra values are discarded and when a vector is lengthened, it is padded out to its new length with NAs (nul for raw vectors).

Both are primitive functions.
Value

The default method for length currently returns a non-negative integer of length 1, except for vectors of more than $2^{31} - 1$ elements, when it returns a double.

For vectors (including lists) and factors the length is the number of elements. For an environment it is the number of objects in the environment, and NULL has length 0. For expressions and pairlists (including language objects and dotlists) it is the length of the pairlist chain. All other objects (including functions) have length one: note that for functions this differs from S.

The replacement form removes all the attributes of x except its names, which are adjusted (and if necessary extended by "").

Warning

Package authors have written methods that return a result of length other than one (Formula) and that return a vector of type double (Matrix), even with non-integer values (earlier versions of sets).

Where a single double value is returned that can be represented as an integer it is returned as a length-one integer vector.

References

See Also

nchar for counting the number of characters in character vectors, lengths for getting the length of every element in a list.

Examples

```r
length(diag(4))  # = 16 (4 x 4)
length(options())  # 12 or more
length(y ~ x1 + x2 + x3)  # 3
length(expression(x, (y <- x^2; y+2), x^y))  # 3
```

```r
## from example(warpbreaks)
require(stats)
fm1 <- lm(breaks ~ wool * tension, data = warpbreaks)
length(fm1$call)  # 3, lm() and two arguments.
length(formula(fm1))  # 3, ~ lhs rhs
```

lengths

Lengths of List or Vector Elements

Description

Get the length of each element of a list or atomic vector (is.atomic) as an integer or numeric vector.

Usage

```r
lengths(x, use.names = TRUE)
```
**lengths** 283

**Arguments**

- **x** a list, list-like such as an *expression* or an atomic vector (for which the result is trivial).
- **use.names** logical indicating if the result should inherit the *names* from x.

**Details**

This function loops over x and returns a compatible vector containing the length of each element in x. Effectively, `length(x[[i]])` is called for all i, so any methods on length are considered.

**Value**

A non-negative *integer* of length `length(x)`, except when any element has a length of more than $2^{31} - 1$ elements, when it returns a double vector. When `use.names` is true, the names are taken from the names on x, if any.

**Note**

One raison d'être of `lengths(x)` is its use as a more efficient version of `sapply(x, length)` and similar *apply* calls to `length`. This is the reason why x may be an atomic vector, even though `lengths(x)` is trivial in that case.

**See Also**

`length` for getting the length of any R object.

**Examples**

```r
require(stats)
## summarize by month
l <- split(airquality$Ozone, airquality$Month)
avgOz <- lapply(l, mean, na.rm=TRUE)
## merge result
airquality$avgOz <- rep(unlist(avgOz, use.names=FALSE), lengths(l))
## but this is safer and cleaner, but can be slower
airquality$avgOz <- unsplit(avgOz, airquality$Month)

## should always be true, except when a length does not fit in 32 bits
stopifnot(identical(lengths(l), vapply(l, length, integer(1L))))

## empty lists are not a problem
x <- list()
stopifnot(identical(lengths(x), integer()))

## nor are "list-like" expressions:
lengths(expression(u, v, 1+ 0:9))

## and we should dispatch to length methods
f <- c(rep(1, 3), rep(2, 6), 3)
dates <- split(as.POSIXlt(Sys.time() + 1:10), f)
stopifnot(identical(lengths(dates), vapply(dates, length, integer(1L))))
```
levels  

Levels Attributes

Description

`levels` provides access to the levels attribute of a variable. The first form returns the value of the levels of its argument and the second sets the attribute.

Usage

```r
levels(x)
levels(x) <- value
```

Arguments

- `x`: an object, for example a factor.
- `value`: A valid value for `levels(x)`. For the default method, `NULL` or a character vector. For the `factor` method, a vector of character strings with length at least the number of levels of `x`, or a named list specifying how to rename the levels.

Details

Both the extractor and replacement forms are generic and new methods can be written for them. The most important method for the replacement function is that for `factor`.

For the factor replacement method, a `NA` in `value` causes that level to be removed from the levels and the elements formerly with that level to be replaced by `NA`.

Note that for a factor, replacing the levels via `levels(x) <- value` is not the same as (and is preferred to) `attr(x, "levels") <- value`.

The replacement function is primitive.

References

See Also

- `nlevels`, `relevel`, `reorder`.

Examples

```r
## assign individual levels
x <- gl(2, 4, 8)
levels(x)[1] <- "low"
levels(x)[2] <- "high"
x

## or as a group
y <- gl(2, 4, 8)
levels(y) <- c("low", "high")
y
```
## combine some levels
z <- gl(3, 2, 12, labels = c("apple", "salad", "orange"))
z
levels(z) <- c("fruit", "veg", "fruit")
z

## same, using a named list
z <- gl(3, 2, 12, labels = c("apple", "salad", "orange"))
z
levels(z) <- list("fruit" = c("apple", "orange"),
                 "veg" = "salad")
z

## we can add levels this way:
f <- factor(c("a","b"))
levels(f) <- c("c", "a", "b")
f

f <- factor(c("a","b"))
levels(f) <- list(C = "C", A = "a", B = "b")
f

---

**libcurlVersion**

*Report Version of libcurl*

### Description

Report version of `libcurl` in use.

### Usage

`libcurlVersion()`

### Value

A character string, with value the `libcurl` version in use or "" if none is. If `libcurl` is available, has attributes

- `ssl_version`: A character string naming the SSL/TLS implementation and version, possibly "none". It is intended for the version of OpenSSL used, but not all implementations of `libcurl` use OpenSSL — for example macOS reports "SecureTransport", its wrapper for SSL/TLS.
- `libssh_version`: A character string naming the `libssh` version, which may or may not be available (it is used for e.g. `scp` and `sftp` protocols). Where present, something like "libssh2/1.5.0".
- `protocols`: A character vector of the names of supported protocols, also known as ‘schemes’ when part of a URL.

### Warning

In late 2017 a `libcurl` installation was seen divided into two libraries, `libcurl` and `libcurl-feature`, and the first had been updated but not the second. As the compiled function recording the version was in the latter, the version reported by `libcurlVersion` was misleading.
See Also

`extSoftVersion` for versions of other third-party software.

`curlGetHeaders`, `download.file` and `url` for functions which (optionally) use `libcurl`.

`http://curl.haxx.se/docs/sslcerts.html` and `http://curl.haxx.se/docs/ssl-compared.html` for more details on SSL versions (the current standard being known as TLS). Normally `libcurl` used with R uses SecureTransport on macOS, OpenSSL on Windows and GnuTLS, NSS or OpenSSL on Unix-alikes. (At the time of writing Debian-based Linuxen use GnuTLS and RedHat-based ones use NSS, but it has been announced that Fedora 27 will switch to OpenSSL.)

Examples

```r
libcurlVersion()
```

---

### libPaths

#### Search Paths for Packages

**Description**

`.libPaths` gets/set the library trees within which packages are looked for.

**Usage**

`.libPaths(new)`

- `.Library`
- `.Library.site`

**Arguments**

- `new` a character vector with the locations of R library trees. Tilde expansion (`path.expand`) is done, and if any element contains one of `*?[]`, globbing is done where supported by the platform: see `Sys.glob`.

**Details**

- `.Library` is a character string giving the location of the default library, the `library` subdirectory of `R_HOME`.
- `.Library.site` is a (possibly empty) character vector giving the locations of the site libraries, by default the `site-library` subdirectory of `R_HOME` (which may not exist).
- `.libPaths` is used for getting or setting the library trees that R knows about (and hence uses when looking for packages). If called with argument `new`, the library search path is set to the existing directories in `unique(c(new, .Library.site, .Library))` and this is returned. If given no argument, a character vector with the currently active library trees is returned.

How paths `new` with a trailing slash are treated is OS-dependent. On a POSIX filesystem existing directories can usually be specified with a trailing slash: on Windows filepaths with a trailing slash (or backslash) are invalid and so will never be added to the library search path.

The library search path is initialized at startup from the environment variable `R_LIBS` (which should be a colon-separated list of directories at which R library trees are rooted) followed by those in environment variable `R_LIBS_USER`. Only directories which exist at the time will be included.
library

By default `R_LIBS` is unset, and `R_LIBS_USER` is set to directory ‘`R/R.version$platform-library/x.y`’ of the home directory (or ‘`Library/R/x.y/library`’ for CRAN macOS builds), for R x.y.z.

`.Library.site` can be set via the environment variable `R_LIBS_SITE` (as a non-empty colon-separated list of library trees).

Both `R_LIBS_USER` and `R_LIBS_SITE` feature possible expansion of specifiers for R version specific information as part of the startup process. The possible conversion specifiers all start with a ‘%’ and are followed by a single letter (use ‘%%’ to obtain ‘%’), with currently available conversion specifications as follows:

- ‘%V’ R version number including the patchlevel (e.g., ‘2.5.0’).
- ‘%v’ R version number excluding the patchlevel (e.g., ‘2.5’).
- ‘%p’ the platform for which R was built, the value of `R.version$platform`.
- ‘%o’ the underlying operating system, the value of `R.version$os`.
- ‘%a’ the architecture (CPU) R was built on/for, the value of `R.version$arch`.

(See `version` for details on R version information.)

Function `.libPaths` always uses the values of `.Library` and `.Library.site` in the base namespace. `.Library.site` can be set by the site in ‘`Rprofile.site`’, which should be followed by a call to `.libPaths(.libPaths())` to make use of the updated value.

For consistency, the paths are always normalized by `normalizePath(winslash = "/")`.

**Value**

A character vector of file paths.

**References**

`library`

**Examples**

```r
.libPaths()
# all library trees R knows about
```

---

**library**

*Loading/Attaching and Listing of Packages*

**Description**

`library` and `require` load and attach add-on packages.
library

Usage

library(package, help, pos = 2, lib.loc = NULL,  
  character.only = FALSE, logical.return = FALSE,  
  warn.conflicts = TRUE, quietly = FALSE,  
  verbose =getOption("verbose")

require(package, lib.loc = NULL, quietly = FALSE,  
  warn.conflicts = TRUE,  
  character.only = FALSE)

Arguments

package, help  the name of a package, given as a name or literal character string, or a character  
  string, depending on whether character.only is FALSE (default) or TRUE.

pos  the position on the search list at which to attach the loaded namespace. Can also  
  be the name of a position on the current search list as given by search().

lib.loc  a character vector describing the location of R library trees to search through, or  
  NULL. The default value of NULL corresponds to all libraries currently known to  
  .libPaths(). Non-existent library trees are silently ignored.

classic.return  a logical indicating whether package or help can be assumed to be character  
  strings.

logical.return  logical. If it is TRUE, FALSE or TRUE is returned to indicate success.

warn.conflicts  logical. If TRUE, warnings are printed about conflicts from attaching the new  
  package. A conflict is a function masking a function, or a non-function masking  
  a non-function.

verbose  a logical. If TRUE, additional diagnostics are printed.

quietly  a logical. If TRUE, no message confirming package attaching is printed, and most  
  often, no errors/warnings are printed if package attaching fails.

Details

library(package) and require(package) both load the namespace of the package with name  
package and attach it on the search list. require is designed for use inside other functions; it returns  
FALSE and gives a warning (rather than an error as library() does by default) if the package does not exist. Both functions check and update the list of currently attached packages and do not reload  
a namespace which is already loaded. (If you want to reload such a package, call detach(unload =  
TRUE) or unloadNamespace first.) If you want to load a package without attaching it on the search  
list, see requireNamespace.

To suppress messages during the loading of packages use suppressPackageStartupMessages:  
this will suppress all messages from R itself but not necessarily all those from package authors.

If library is called with no package or help argument, it lists all available packages in the libraries specified by lib.loc, and returns the corresponding information in an object of class "libraryIQR". (The structure of this class may change in future versions.) Use .packages(all = TRUE) to obtain just the names of all available packages, and  
installed.packages() for even more information.

library(help = somename) computes basic information about the package somename, and returns  
this in an object of class "packageInfo". (The structure of this class may change in future  
versions.) When used with the default value (NULL) for lib.loc, the attached packages are searched  
before the libraries.
Value

Normally library returns (invisibly) the list of attached packages, but TRUE or FALSE if logical.return is TRUE. When called as library() it returns an object of class "libraryIQR", and for library(help=), one of class "packageInfo".

require returns (invisibly) a logical indicating whether the required package is available.

Licenses

Some packages have restrictive licenses, and there is a mechanism to allow users to be aware of such licenses. If getOption("checkPackageLicense") == TRUE, then at first use of a package with a not-known-to-be-FOSS (see below) license the user is asked to view and accept the license: a list of accepted licenses is stored in file ‘~/.R/licensed’. In a non-interactive session it is an error to use such a package whose license has not already been recorded as accepted.

As from R 3.4.0 the license check is done when the namespace is loaded.

Free or Open Source Software (FOSS, e.g. https://en.wikipedia.org/wiki/FOSS) packages are determined by the same filters used by available.packages but applied to just the current package, not its dependencies.

There can also be a site-wide file ‘R_HOME/etc/licensed.site’ of packages (one per line).

Formal methods

library takes some further actions when package methods is attached (as it is by default). Packages may define formal generic functions as well as re-defining functions in other packages (notably base) to be generic, and this information is cached whenever such a namespace is loaded after methods and re-defined functions (implicit generics) are excluded from the list of conflicts. The caching and check for conflicts require looking for a pattern of objects; the search may be avoided by defining an object .noGenerics (with any value) in the namespace. Naturally, if the package does have any such methods, this will prevent them from being used.

Note

library and require can only load/attach an installed package, and this is detected by having a ‘DESCRIPTION’ file containing a ‘Built:’ field.

Under Unix-alikes, the code checks that the package was installed under a similar operating system as given by R.version$platform (the canonical name of the platform under which R was compiled), provided it contains compiled code. Packages which do not contain compiled code can be shared between Unix-alikes, but not to other OSes because of potential problems with line endings and OS-specific help files. If sub-architectures are used, the OS similarity is not checked since the OS used to build may differ (e.g. i386-pc-linux-gnu code can be built on an x86_64-unknown-linux-gnu OS).

The package name given to library and require must match the name given in the package’s ‘DESCRIPTION’ file exactly, even on case-insensitive file systems such as are common on Windows and macOS.

The initial set of packages attached is set by options(defaultPackages=); see also Startup.

Examples

library() # list all available packages
library(lib.loc = .Library) # list all packages in the default library
library(help = splines) # documentation on package 'splines'
library(splines) # attach package 'splines'
require(splines) # the same
search() # "splines", too
detach("package:splines")

# if the package name is in a character vector, use
pkg <- "splines"
library(pkg, character.only = TRUE)
detach(pos = match("package", pkg, sep = ":"), search())

require(pkg, character.only = TRUE)
detach(pos = match("package", pkg, sep = ":"), search())

require(nonexistent) # FALSE

## Not run:
## if you want to mask as little as possible, use
library(mypkg, pos = "package:base")

## End(Not run)

library.dynam

Loading DLLs from Packages

Description

Load the specified file of compiled code if it has not been loaded already, or unloads it.

Usage

library.dynam(chname, package, lib.loc, verbose = getOption("verbose",),
 file.ext = .Platform$dynlib.ext, ...)

library.dynam.unload(chname, libpath, verbose = getOption("verbose",),
 file.ext = .Platform$dynlib.ext)

.dynLibs(new)
library.dynam

Arguments

chname  a character string naming a DLL (also known as a dynamic shared object or library) to load.
package  a character vector with the name of package.
lib.loc  a character vector describing the location of \texttt{R} library trees to search through.
lib.path  the path to the loaded package whose DLL is to be unloaded.
verbose  a logical value indicating whether an announcement is printed on the console before loading the DLL. The default value is taken from the verbose entry in the system \texttt{options}.
file.ext  the extension (including "." if used) to append to the file name to specify the library to be loaded. This defaults to the appropriate value for the operating system.
...  additional arguments needed by some libraries that are passed to the call to \texttt{dyn.load} to control how the library and its dependencies are loaded.
new  a list of "DLLInfo" objects corresponding to the DLLs loaded by packages. Can be missing.

Details

See \texttt{dyn.load} for what sort of objects these functions handle.
library.dynam is designed to be used inside a package rather than at the command line, and should really only be used inside \texttt{.onLoad}. The system-specific extension for DLLs (e.g., ".so" or ".sl" on Unix-alike systems, ".dll" on Windows) should not be added.
library.dynam.unload is designed for use in \texttt{.onUnload}: it unloads the DLL and updates the value of \texttt{.dynLibs()}

\texttt{.dynLibs} is used for getting (with no argument) or setting the DLLs which are currently loaded by packages (using \texttt{library.dynam}).

Value

If \texttt{chname} is not specified, \texttt{library.dynam} returns an object of class "DLLInfoList" corresponding to the DLLs loaded by packages.

If \texttt{chname} is specified, an object of class "DLLInfo" that identifies the DLL and which can be used in future calls is returned invisibly. Note that the class "DLLInfo" has a method for \$ which can be used to resolve native symbols within that DLL.

\texttt{library.dynam.unload} invisibly returns an object of class "DLLInfo" identifying the DLL successfully unloaded.

\texttt{.dynLibs} returns an object of class "DLLInfoList" corresponding corresponding to its current value.

Warning

Do not use \texttt{dyn.unload} on a DLL loaded by \texttt{library.dynam}: use \texttt{library.dynam.unload} to ensure that \texttt{.dynLibs} gets updated. Otherwise a subsequent call to \texttt{library.dynam} will be told the object is already loaded.

Note that whether or not it is possible to unload a DLL and then reload a revised version of the same file is OS-dependent: see the ‘Value’ section of the help for \texttt{dyn.unload}. 
References

See Also

getLoadedDLLs for information on "DLLInfo" and "DLLInfoList" objects.
.onLoad, library, dyn.load, .packages, .libPaths
SHLIB for how to create suitable DLLs.

Examples

```r
## Which DLLs were dynamically loaded by packages?
library.dynam()

## More on library.dynam.unload():
require(nlme)
nlme:::.onUnload # shows library.dynam.unload() call
detach("package:nlme") # by default, unload=FALSE, so,
tail(library.dynam(), 2)# nlme still there

## How to unload the DLL ?
## Best is to unload the namespace, unloadNamespace("nlme")
## If we need to do it separately which should be exceptional:
pd.file <- attr(packageDescription("nlme"), "file")
library.dynam.unload("nlme", libpath = sub("/Meta.*", '', pd.file))
tail(library.dynam(), 2)# 'nlme' is gone now
unloadNamespace("nlme") # now gives warning
```

license

The R License Terms

Description

The license terms under which R is distributed.

Usage

```r
license()
licence()
```

Details

R is distributed under the terms of the GNU GENERAL PUBLIC LICENSE, either Version 2, June 1991 or Version 3, June 2007. A copy of the version 2 license is in file `$R_HOME/doc/COPYING` and can be viewed by RShowDoc("COPYING"). Version 3 of the license can be displayed by RShowDoc("GPL-3").

A small number of files (some of the API header files) are distributed under the LESSER GNU GENERAL PUBLIC LICENSE, version 2.1 or later. A copy of this license is in file `$R_SHARE_DIR/licenses/LGPL-2.1` and can be viewed by RShowDoc("LGPL-2.1"). Version 3 of the license can be displayed by RShowDoc("LGPL-3").
Description

Functions to construct, coerce and check for both kinds of R lists.

Usage

```
list(...)  
pairlist(...)  

as.list(x, ...)  
## S3 method for class 'environment'
as.list(x, all.names = FALSE, sorted = FALSE, ...)
as.pairlist(x)  

is.list(x)  
is.pairlist(x)  

alist(...)
```

Arguments

```
...  
objects, possibly named.  
x  
object to be coerced or tested.  
all.names  
a logical indicating whether to copy all values or (default) only those whose names do not begin with a dot.  
sorted  
a logical indicating whether the names of the resulting list should be sorted (increasingly). Note that this is somewhat costly, but may be useful for comparison of environments.
```

Details

Almost all lists in R internally are Generic Vectors, whereas traditional dotted pair lists (as in LISP) remain available but rarely seen by users (except as formals of functions).

The arguments to list or pairlist are of the form value or tag = value. The functions return a list or dotted pair list composed of its arguments with each value either tagged or untagged, depending on how the argument was specified.

alist handles its arguments as if they described function arguments. So the values are not evaluated, and tagged arguments with no value are allowed whereas list simply ignores them. alist is most often used in conjunction with formals.

as.list attempts to coerce its argument to a list. For functions, this returns the concatenation of the list of formal arguments and the function body. For expressions, the list of constituent elements is returned. as.list is generic, and as the default method calls as.vector(mode = "list") for a non-list, methods for as.vector may be invoked. as.list turns a factor into a list of one-element factors. Attributes may be dropped unless the argument already is a list or expression. (This is inconsistent with functions such as as.character which always drop attributes, and is for efficiency since lists can be expensive to copy.)
is.list returns TRUE if and only if its argument is a list or a pairlist of length > 0. is.pairlist returns TRUE if and only if the argument is a pairlist or NULL (see below).

The "environment" method for as.list copies the name-value pairs (for names not beginning with a dot) from an environment to a named list. The user can request that all named objects are copied. Unless sorted = TRUE, the list is in no particular order (the order depends on the order of creation of objects and whether the environment is hashed). No enclosing environments are searched. (Objects copied are duplicated so this can be an expensive operation.) Note that there is an inverse operation, the as.environment() method for list objects.

An empty pairlist, pairlist() is the same as NULL. This is different from list(): some but not all operations will promote an empty pairlist to an empty list.

as.pairlist is implemented as as.vector(x, "pairlist"), and hence will dispatch methods for the generic function as.vector. Lists are copied element-by-element into a pairlist and the names of the list used as tags for the pairlist: the return value for other types of argument is undocumented.

list, is.list and is.pairlist are primitive functions.

References

See Also
vector("list", length) for creation of a list with empty components; c, for concatenation; formals.unlist is an approximate inverse to as.list(). 'plotmath' for the use of list in plot annotation.

Examples

require(graphics)

# create a plotting structure
pts <- list(x = cars[,1], y = cars[,2])
plot(pts)

is.pairlist(.Options) # a user-level pairlist

## "pre-allocate" an empty list of length 5
vector("list", 5)

# Argument lists
f <- function() x
# Note the specification of a "..." argument:
formals(f) <- al <- alist(x = , y = 2+3, ... = )
f al

## environment->list coercion

el $ a <- 10
el $ b <- 20
as.list(el)
list.files

List the Files in a Directory/Folder

Description

These functions produce a character vector of the names of files or directories in the named directory.

Usage

\[
\text{list.files(path = ".", pattern = NULL, all.files = FALSE, full.names = FALSE, recursive = FALSE, ignore.case = FALSE, include.dirs = FALSE, no.. = FALSE)}
\]

\[
\text{dir(path = ".", pattern = NULL, all.files = FALSE, full.names = FALSE, recursive = FALSE, ignore.case = FALSE, include.dirs = FALSE, no.. = FALSE)}
\]

\[
\text{list.dirs(path = ".", full.names = TRUE, recursive = TRUE)}
\]

Arguments

- **path**: a character vector of full path names; the default corresponds to the working directory, `getwd()`. Tilde expansion (see `path.expand`) is performed. Missing values will be ignored.
- **pattern**: an optional regular expression. Only file names which match the regular expression will be returned.
- **all.files**: a logical value. If FALSE, only the names of visible files are returned. If TRUE, all file names will be returned.
- **full.names**: a logical value. If TRUE, the directory path is prepended to the file names to give a relative file path. If FALSE, the file names (rather than paths) are returned.
- **recursive**: logical. Should the listing recurse into directories?
- **ignore.case**: logical. Should pattern-matching be case-insensitive?
- **include.dirs**: logical. Should subdirectory names be included in recursive listings? (They always are in non-recursive ones).
- **no..**: logical. Should both "." and ".." be excluded also from non-recursive listings?

Value

A character vector containing the names of the files in the specified directories, or "" if there were no files. If a path does not exist or is not a directory or is unreadable it is skipped, with a warning. The files are sorted in alphabetical order, on the full path if full.names = TRUE.

list.dirs implicitly has all.files = TRUE, and if recursive = TRUE, the answer includes path itself (provided it is a readable directory).

Note

File naming conventions are platform dependent. The pattern matching works with the case of file names as returned by the OS.

On a POSIX filesystem recursive listings will follow symbolic links to directories.
list2env

From A List, Build or Add To an Environment

Description

From a named list \( x \), create an environment containing all list components as objects, or “multi-assign” from \( x \) into a pre-existing environment.

Usage

```r
list2env(x, envir = NULL, parent = parent.frame(),
          hash = (length(x) > 100), size = max(29L, length(x)))
```

Arguments

- **x**: a list, where `names(x)` must not contain empty (""") elements.
- **envir**: an environment or NULL.
- **parent**: (for the case `envir = NULL`): a parent frame aka enclosing environment, see `new.env`.
- **hash**: (for the case `envir = NULL`): logical indicating if the created environment should use hashing, see `new.env`.
- **size**: (in the case `envir = NULL`, `hash = TRUE`): hash size, see `new.env`.

Details

This will be very slow for large inputs unless hashing is used on the environment.

Environments must have uniquely named entries, but named lists need not: where the list has duplicate names it is the last element with the name that is used. Empty names throw an error.
Value

An `environment`, either newly created (as by `new.env`) if the `envir` argument was `NULL`, otherwise the updated environment `envir`. Since environments are never duplicated, the argument `envir` is also changed.

Author(s)

Martin Maechler

See Also

`environment`, `new.env`, `as.environment`; further, `assign`.

The (semantical) “inverse”: `as.list.environment`.

Examples

```r
L <- list(a = 1, b = 2:4, p = pi, ff = gl(3, 4, labels = LETTERS[1:3]))
e <- list2env(L)
ls(e)
stopifnot(ls(e) == sort(names(L)),
         identical(L$b, e$b)) # "$" working for environments as for lists

## consistency, when we do the inverse:
ll <- as.list(e) # -> dispatching to the as.list.environment() method
rbind(names(L), names(ll)) # not in the same order, typically,
    # but the same content:
stopifnot(identical(L[sort.list(names(L))],
    ll[sort.list(names(ll))]))

## now add to e -- can be seen as a fast "multi-assign":
list2env(list(abc = LETTERS, note = "just an example",
               df = data.frame(x = rnorm(20), y = rbinom(20, 1, pr = 0.2)),
               envir = e),
utils::ls.str(e)
```
load can load R objects saved in the current or any earlier format. It can read a compressed file (see save) directly from a file or from a suitable connection (including a call to url).

A not-open connection will be opened in mode "rb" and closed after use. Any connection other than a gzfile or gzcon connection will be wrapped in gzcon to allow compressed saves to be handled: note that this leaves the connection in an altered state (in particular, binary-only), and that it needs to be closed explicitly (it will not be garbage-collected).

Only R objects saved in the current format (used since R 1.4.0) can be read from a connection. If no input is available on a connection a warning will be given, but any input not in the current format will result in an error.

Loading from an earlier version will give a warning about the ‘magic number’: magic numbers 1971:1977 are from R < 0.99.0, and RD[ABX]1 from R 0.99.0 to R 1.3.1. These are all obsolete, and you are strongly recommended to re-save such files in a current format.

The verbose argument is mainly intended for debugging. If it is TRUE, then as objects from the file are loaded, their names will be printed to the console. If verbose is set to an integer value greater than one, additional names corresponding to attributes and other parts of individual objects will also be printed. Larger values will print names to a greater depth.

Objects can be saved with references to namespaces, usually as part of the environment of a function or formula. Such objects can be loaded even if the namespace is not available: it is replaced by a reference to the global environment with a warning. The warning identifies the first object with such a reference (but there may be more than one).

Value

A character vector of the names of objects created, invisibly.

Warning

Saved R objects are binary files, even those saved with ascii = TRUE, so ensure that they are transferred without conversion of end of line markers. load tries to detect such a conversion and gives an informative error message.

load(<file>) replaces all existing objects with the same names in the current environment (typically your workspace, .GlobalEnv) and hence potentially overwrites important data. It is considerably safer to use envir = to load into a different environment, or to attach(file) which load()s into a new entry in the search path.

See Also

save, download.file; further attach as wrapper for load().

For other interfaces to the underlying serialization format, see unserialize and readRDS.

Examples

```r
## save all data
xx <- pi # to ensure there is some data
save(list = ls(all = TRUE), file= "all.RData")
rm(xx)

## restore the saved values to the current environment
local({
  load("all.RData")
})
```
ls()
})

xx <- exp(1:3)
# restore the saved values to the user's workspace
load("all.RData") # which is here *equivalent* to
# load("all.RData", .GlobalEnv)
# This however annihilates all objects in .GlobalEnv with the same names!
xx # no longer exp(1:3)
rm(xx)
attach("all.RData") # safer and will warn about masked objects w/ same name in .GlobalEnv
ls(pos = 2)
# also typically need to cleanup the search path:
detach("file:all.RData")

# clean up (the example):
unlink("all.RData")

# Not run:
con <- url("http://some.where.net/R/data/example.rda")
# print the value to see what objects were created.
print(load(con))
close(con) # url() always opens the connection

# End(Not run)

locales

Query or Set Aspects of the Locale

description
Get details of or set aspects of the locale for the R process.

Usage
Sys.getlocale(category = "LC_ALL")
Sys.setlocale(category = "LC_ALL", locale = "")

Arguments
category character string. The following categories should always be supported:
"LC_ALL", "LC_COLLATE", "LCCTYPE", "LC_MONETARY", "LC_NUMERIC" and
"LC_TIME". Some systems (not Windows) will also support "LC_MESSAGES", "LC_PAPER" and "LC_MEASUREMENT".
locale character string. A valid locale name on the system in use. Normally "" (the
default) will pick up the default locale for the system.

details
The locale describes aspects of the internationalization of a program. Initially most aspects of the
locale of R are set to "C" (which is the default for the C language and reflects North-American
usage). R sets "LCCTYPE" and "LC_COLLATE", which allow the use of a different character set and
alphabetic comparisons in that character set (including the use of sort), "LC_MONETARY" (for use
by `Sys.localeconv`) and "LC_TIME" may affect the behaviour of `as.POSIXlt` and `strptime` and functions which use them (but not `date`).

The first seven categories described here are those specified by POSIX. "LC_MESSAGES" will be "C" on systems that do not support message translation, and is not supported on Windows. Trying to use an unsupported category is an error for `Sys.setlocale`.

Note that setting category "LC_ALL" sets only categories "LC_COLLATE", "LC_CTYPE", "LC_MONETARY" and "LC_TIME".

Attempts to set an invalid locale are ignored. There may or may not be a warning, depending on the OS.

Attempts to change the character set (by `Sys.setlocale("LC_CTYPE",` ) if that implies a different character set) during a session may not work and are likely to lead to some confusion.

Note that the `LANGUAGE` environment variable has precedence over "LC_MESSAGES" in selecting the language for message translation on most R platforms.

On platforms where ICU is used for collation the locale used for collation can be reset by `icuSetCollate`). Except on Windows, the initial setting is taken from the "LC_COLLATE" category, and it is reset when this is changed by a call to `Sys.setlocale`.

**Value**

A character string of length one describing the locale in use (after setting for `Sys.setlocale`), or an empty character string if the current locale settings are invalid or `NULL` if locale information is unavailable.

For `category = "LC_ALL"` the details of the string are system-specific: it might be a single locale name or a set of locale names separated by "/" (Solaris, macOS) or ";" (Windows, Linux). For portability, it is best to query categories individually: it is not necessarily the case that the result of `foo <- Sys.getlocale()` can be used in `Sys.setlocale("LC_ALL", locale = foo)`.

**Warning**

Setting "LC_NUMERIC" to any value other than "C" may cause R to function anomalously, so gives a warning. Input conversions in R itself are unaffected, but the reading and writing of ASCII save files will be, as may packages which do their own input/output.

Setting it temporarily on a Unix-alike to produce graphical or text output may work well enough, but `options(OutDec)` is often preferable.

Almost all the output routines used by R itself under Windows ignore the setting of "LC_NUMERIC" since they make use of the Trio library which is not internationalized.

**Note**

Changing the values of locale categories whilst R is running ought to be noticed by the OS services, and usually is but exceptions have been seen (usually in collation services).

**See Also**

`strptime` for uses of `category = "LC_TIME"`. `Sys.localeconv` for details of numerical and monetary representations.

`l10n_info` gives some summary facts about the locale and its encoding.

The ‘R Installation and Administration’ manual for background on locales and how to find out locale names on your system.
Examples

Sys.getlocale()
Sys.getlocale("LC_TIME")
## Not run:
Sys.setlocale("LC_TIME", "de")  # Solaris: details are OS-dependent
Sys.setlocale("LC_TIME", "de_DE")  # Many Unix-alikes
Sys.setlocale("LC_TIME", "de_DE.UTF-8")  # Linux, macOS, other Unix-alikes
Sys.setlocale("LC_TIME", "de.DE.utf8")  # some Linux versions
Sys.setlocale("LC_TIME", "German")  # Windows

## End(Not run)
Sys.getlocale("LC_PAPER")  # may or may not be set

## Not run:
Sys.setlocale("LC_COLLATE", "C")  # turn off locale-specific sorting,
# usually (but not on all platforms)
## End(Not run)

log

Logarithms and Exponentials

Description

log computes logarithms, by default natural logarithms, \( \log_{10} \) computes common (i.e., base 10) logarithms, and \( \log_2 \) computes binary (i.e., base 2) logarithms. The general form \( \log(x, \text{base}) \) computes logarithms with base base.

\( \log_1(x) \) computes \( \log(1 + x) \) accurately also for \( |x| \ll 1 \).

exp computes the exponential function.

\( \exp_1(x) \) computes \( \exp(x) - 1 \) accurately also for \( |x| \ll 1 \).

Usage

\[ \log(x, \text{base} = \exp(1)) \]
\[ \logb(x, \text{base} = \exp(1)) \]
\[ \log_{10}(x) \]
\[ \log_{2}(x) \]

\[ \log_1p(x) \]

\[ \exp(x) \]
\[ \exp_1(x) \]

Arguments

\( x \) a numeric or complex vector.

\( \text{base} \) a positive or complex number: the base with respect to which logarithms are computed. Defaults to \( e=\exp(1) \).
Details

All except logb are generic functions: methods can be defined for them individually or via the Math group generic.

log10 and log2 are only convenience wrappers, but logs to bases 10 and 2 (whether computed via log or the wrappers) will be computed more efficiently and accurately where supported by the OS. Methods can be set for them individually (and otherwise methods for log will be used).

logb is a wrapper for log for compatibility with S. If (S3 or S4) methods are set for log they will be dispatched. Do not set S4 methods on logb itself.

All except log are primitive functions.

Value

A vector of the same length as x containing the transformed values. log(0) gives -Inf, and log(x) for negative values of x is NaN. exp(-Inf) is 0.

For complex inputs to the log functions, the value is a complex number with imaginary part in the range \([-\pi, \pi]\): which end of the range is used might be platform-specific.

S4 methods

exp, expm1, log, log10, log2 and log1p are S4 generic and are members of the Math group generic.

Note that this means that the S4 generic for log has a signature with only one argument, x, but that base can be passed to methods (but will not be used for method selection). On the other hand, if you only set a method for the Math group generic then base argument of log will be ignored for your class.

Source

log1p and expm1 may be taken from the operating system, but if not available there then they are based on the Fortran subroutine dlnrel by W. Fullerton of Los Alamos Scientific Laboratory (see http://www.netlib.org/slatec/fnlib/dlnrel.f and (for small x) a single Newton step for the solution of log1p(y) = x respectively.

References

See Also

Trig, sqrt, Arithmetic.

Examples

log(exp(3))
log10(1e7) # = 7

x <- 10^-(1+2*1:9)
cbind(x, log(1+x), log1p(x), exp(x)-1, expm1(x))
Description

These operators act on raw, logical and number-like vectors.

Usage

! x
x & y
x && y
x | y
x || y
xor(x, y)
isTRUE (x)
isFALSE(x)

Arguments

x, y      raw or logical or ‘number-like’ vectors (i.e., of types double (class numeric), integer and complex)), or objects for which methods have been written.

Details

! indicates logical negation (NOT).
& and && indicate logical AND and | and || indicate logical OR. The shorter form performs elementwise comparisons in much the same way as arithmetic operators. The longer form evaluates left to right examining only the first element of each vector. Evaluation proceeds only until the result is determined. The longer form is appropriate for programming control-flow and typically preferred in if clauses.
xor indicates elementwise exclusive OR.
isTRUE(x) is the same as { is.logical(x) && length(x) == 1 && !is.na(x) && x }; isFALSE() is defined analogously. Consequently, if(isTRUE(cond)) may be preferable to if(cond) because of NAs.
In earlier R versions, isTRUE <- function(x) identical(x, TRUE), had the drawback to be false e.g., for x <- c(val = TRUE).
Numeric and complex vectors will be coerced to logical values, with zero being false and all non-zero values being true. Raw vectors are handled without any coercion for !, & and | and xor, with these operators being applied bitwise (so ! is the 1s-complement).
The operators !, &, and | are generic functions: methods can be written for them individually or via the Ops (or S4 Logic, see below) group generic function. (See Ops for how dispatch is computed.)
NA is a valid logical object. Where a component of x or y is NA, the result will be NA if the outcome is ambiguous. In other words NA & TRUE evaluates to NA, but NA & FALSE evaluates to FALSE. See the examples below.
See Syntax for the precedence of these operators: unlike many other languages (including S) the AND and OR operators do not have the same precedence (the AND operators have higher precedence than the OR operators).
Value

For !, a logical or raw vector(for raw x) of the same length as x: names, dims and dimnames are copied from x, and all other attributes (including class) if no coercion is done.

For |, &, and xor a logical or raw vector. If involving a zero-length vector the result has length zero. Otherwise, the elements of shorter vectors are recycled as necessary (with a warning when they are recycled only fractionally). The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument, the first if they are of the same length. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. For time series, these operations are allowed only if the series are compatible, when the class and tsp attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and dimnames are taken from first argument if it is an array, otherwise the second.

For ||, && and isTRUE, a length-one logical vector.

S4 methods

!, & and | are S4 generics, the latter two part of the Logic group generic (and hence methods need argument names e1, e2).

Note

The elementwise operators are sometimes called as functions as e.g. `&`(x, y): see the description of how argument-matching is done in Ops.

References

See Also

TRUE or logical.

any and all for OR and AND on many scalar arguments.

Syntax for operator precedence.

bitwAnd for bitwise versions for integer vectors.

Examples

```r
y <- 1 + (x <- stats::rpois(50, lambda = 1.5) / 4 - 1)
x[(x > 0) & (x < 1)] # all x values between 0 and 1
if (any(x == 0) || any(y == 0)) "zero encountered"
```

```r
# construct truth tables :

x <- c(NA, FALSE, TRUE)

names(x) <- as.character(x)

outer(x, x, "&") #& table
out(x, x, ")") # OR table
```
**logical**

**Logical Vectors**

**Description**

Create or test for objects of type "logical", and the basic logical constants.

**Usage**

```r
TRUE
FALSE
T; F
logical(length = 0)
as.logical(x, ...)
is.logical(x)
```

**Arguments**

- `length` A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
- `x` object to be coerced or tested.
- `...` further arguments passed to or from other methods.

**Details**

TRUE and FALSE are reserved words denoting logical constants in the R language, whereas T and F are global variables whose initial values set to these. All four are logical(1) vectors.

Logical vectors are coerced to integer vectors in contexts where a numerical value is required, with TRUE being mapped to 1L, FALSE to 0L and NA to NA_integer_.

**Value**

`logical` creates a logical vector of the specified length. Each element of the vector is equal to FALSE.

`as.logical` attempts to coerce its argument to be of logical type. For factors, this uses the `levels` (labels). Like `as.vector` it strips attributes including names. Character strings `c("T", "TRUE", "True", "true")` are regarded as true, `c("F", "FALSE", "False", "false")` as false, and all others as NA.

`is.logical` returns TRUE or FALSE depending on whether its argument is of logical type or not.

**References**

**See Also**

NA, the other logical constant.
Long Vectors

Description

Vectors of $2^{31}$ or more elements were added in R 3.0.0.

Details

Prior to R 3.0.0, all vectors in R were restricted to at most $2^{31} - 1$ elements and could be indexed by integer vectors.

Currently all atomic (raw, logical, integer, numeric, complex, character) vectors, lists and expressions can be much longer on 64-bit platforms: such vectors are referred to as ‘long vectors’ and have a slightly different internal structure. In theory they can to $2^{52}$ elements, but address space limits of current CPUs and OSes will be much smaller. Such objects will have a length that is expressed as a double, and can be indexed by double vectors.

Arrays (including matrices) can be based on long vectors provided each of their dimensions is at most $2^{31} - 1$: thus there are no 1-dimensional long arrays.

R code typically only needs minor changes to work with long vectors, maybe only checking that as.integer is not used unnecessarily for e.g. lengths. However, compiled code typically needs quite extensive changes. Note that the .C and .Fortran interfaces do not accept long vectors, so .Call (or similar) has to be used.

Because of the storage requirements (a minimum of 64 bytes per character string), character vectors are only going to be usable if they have a small number of distinct elements, and even then factors will be more efficient (4 bytes per element rather than 8). So it is expected that most of the usage of long vectors will be integer vectors (including factors) and numeric vectors.

Matrix algebra

It is now possible to use $m \times n$ matrices with more than 2 billion elements. Whether matrix algebra (including %*%, crossprod, svd, qr, solve and eigen) will actually work is somewhat implementation dependent, including the Fortran compiler used and if an external BLAS or LAPACK is used.

An efficient parallel BLAS implementation will often be important to obtain usable performance. For example on one particular platform chol on a 47,000 square matrix took about 5 hours with the internal BLAS, 21 minutes using an optimized BLAS on one core, and 2 minutes using an optimized BLAS on 16 cores.

lower.tri

Lower and Upper Triangular Part of a Matrix

Description

Returns a matrix of logicals the same size of a given matrix with entries TRUE in the lower or upper triangle.

Usage

lower.tri(x, diag = FALSE)
upper.tri(x, diag = FALSE)
Arguments

- **x**: a matrix or other \texttt{R} object with 	exttt{length(dim(x)) == 2}. For back compatibility reasons, when the above is not fulfilled, \texttt{as.matrix(x)} is called first.
- **diag**: logical. Should the diagonal be included?

See Also

\texttt{diag}, \texttt{matrix}; further \texttt{row} and \texttt{col} on which \texttt{lower.tri()} and \texttt{upper.tri()} are built.

Examples

\begin{verbatim}
(m2 <- matrix(1:20, 4, 5))
lower.tri(m2)
m2[lower.tri(m2)] <- NA
m2
\end{verbatim}

\texttt{ls}

\emph{List Objects}

Description

\texttt{ls} and \texttt{objects} return a vector of character strings giving the names of the objects in the specified environment. When invoked with no argument at the top level prompt, \texttt{ls} shows what data sets and functions a user has defined. When invoked with no argument inside a function, \texttt{ls} returns the names of the function’s local variables: this is useful in conjunction with \texttt{browser}.

Usage

\begin{verbatim}
ls(name, pos = -1L, envir = as.environment(pos),
   all.names = FALSE, pattern, sorted = TRUE)
objects(name, pos = -1L, envir = as.environment(pos),
   all.names = FALSE, pattern, sorted = TRUE)
\end{verbatim}

Arguments

- **name**: which environment to use in listing the available objects. Defaults to the \textit{current} environment. Although called name for back compatibility, in fact this argument can specify the environment in any form; see the ‘Details’ section.
- **pos**: an alternative argument to name for specifying the environment as a position in the search list. Mostly there for back compatibility.
- **envir**: an alternative argument to name for specifying the environment. Mostly there for back compatibility.
- **all.names**: a logical value. If \texttt{TRUE}, all object names are returned. If \texttt{FALSE}, names which begin with a ‘.’ are omitted.
- **pattern**: an optional \textit{regular expression}. Only names matching \texttt{pattern} are returned. \texttt{glob2rx} can be used to convert wildcard patterns to regular expressions.
- **sorted**: logical indicating if the resulting \texttt{character} should be sorted alphabetically. Note that this is part of \texttt{ls()} may take most of the time.
make.names

Details

The name argument can specify the environment from which object names are taken in one of several forms: as an integer (the position in the search list); as the character string name of an element in the search list; or as an explicit environment (including using sys.frame to access the currently active function calls). By default, the environment of the call to ls or objects is used. The pos and envir arguments are an alternative way to specify an environment, but are primarily there for back compatibility.

Note that the order of strings for sorted = TRUE is locale dependent, see Sys.getlocale. If sorted = FALSE the order is arbitrary, depending if the environment is hashed, the order of insertion of objects, etc.

References

See Also

glob2rx for converting wildcard patterns to regular expressions.
l.s.str for a long listing based on str. apropos (or find) for finding objects in the whole search path; grep for more details on `regular expressions`; class, methods, etc., for object-oriented programming.

Examples

.Ob <- 1
ls(pattern = "O")
ls(pattern = "O", all.names = TRUE)  # also shows ".[foo]"

# shows an empty list because inside myfunc no variables are defined
myfunc <- function() {ls()}
myfunc()

# define a local variable inside myfunc
myfunc <- function() {y <- 1; ls()}
myfunc()  # shows "y"

make.names Make Syntactically Valid Names

Description

Make syntactically valid names out of character vectors.

Usage

make.names(names, unique = FALSE, allow_ = TRUE)
make.names

Arguments

names character vector to be coerced to syntactically valid names. This is coerced to
to character if necessary.
unique logical; if TRUE, the resulting elements are unique. This may be desired for, e.g.,
column names.
allow_ logical. For compatibility with R prior to 1.9.0.

Details

A syntactically valid name consists of letters, numbers and the dot or underline characters and starts
with a letter or the dot not followed by a number. Names such as \texttt{.2way} are not valid, and neither
are the \texttt{reserved} words.
The definition of a letter depends on the current locale, but only ASCII digits are considered to be
digits.
The character \\texttt{X} is prepended if necessary. All invalid characters are translated to \\texttt{.}. A missing
value is translated to \\texttt{NA}. Names which match R keywords have a dot appended to them.
Duplicated values are altered by \texttt{make.unique}.

Value

A character vector of same length as names with each changed to a syntactically valid
name, in the
current locale’s encoding.

Warning

Some OSes, notably FreeBSD, report extremely incorrect information about which characters are
alphabetic in some locales (typically, all multi-byte locales including UTF-8 locales). However, R
provides substitutes on Windows, macOS and AIX.

Note

Prior to R version 1.9.0, underscores were not valid in variable names, and code that relies on them
being converted to dots will no longer work. Use allow_ = FALSE for back-compatibility.
allow_ = FALSE is also useful when creating names for export to applications which do not allow
underline in names (for example, S-PLUS and some DBMSs).

See Also

\texttt{make.unique}, \texttt{names}, \texttt{character}, \texttt{data.frame}.

Examples

\begin{verbatim}
make.names(c("a and b", "a-and-b"), unique = TRUE)
  # "a.and.b"  "a.and.b.1"
make.names(c("a and b", "a_and_b"), unique = TRUE)
  # "a_and_b"  "a_and_b"
make.names(c("a and b", "a_and_b"), unique = TRUE, allow_ = FALSE)
  # "a.and.b" "a.and.b.1"
make.names(c("", "X"), unique = TRUE)
  # "X.1"  "X" currently; R up to 3.0.2 gave "X" "X.1"
state.name[make.names(state.name) != state.name] # those 10 with a space
\end{verbatim}
Description

Makes the elements of a character vector unique by appending sequence numbers to duplicates.

Usage

```r
make.unique(names, sep = ".")
```

Arguments

- `names`: a character vector
- `sep`: a character string used to separate a duplicate name from its sequence number.

Details

The algorithm used by `make.unique` has the property that `make.unique(c(A, B)) == make.unique(c(make.unique(A), B))`. In other words, you can append one string at a time to a vector, making it unique each time, and get the same result as applying `make.unique` to all of the strings at once.

If character vector `A` is already unique, then `make.unique(c(A, B))` preserves `A`.

Value

A character vector of same length as `names` with duplicates changed, in the current locale’s encoding.

Author(s)

Thomas P. Minka

See Also

`make.names`

Examples

```r
make.unique(c("a", "a", "a"))
make.unique(c(make.unique(c("a", "a")), "a"))

make.unique(c("a", "a", "a.2", "a"))
make.unique(c(make.unique(c("a", "a")), "a.2", "a"))

rbind(data.frame(x = 1), data.frame(x = 2), data.frame(x = 3))
rbind(rbind(data.frame(x = 1), data.frame(x = 2)), data.frame(x = 3))
```
mapply

Apply a Function to Multiple List or Vector Arguments

Description

mapply is a multivariate version of sapply. mapply applies FUN to the first elements of each ...argument, the second elements, the third elements, and so on. Arguments are recycled if necessary.

Usage

mapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE)

Arguments

FUN    function to apply, found via match.fun.
...
    arguments to vectorize over (vectors or lists of strictly positive length, or all of
    zero length). See also ‘Details’.
MoreArgs    a list of other arguments to FUN.
SIMPLIFY    logical or character string; attempt to reduce the result to a vector, matrix or
    higher dimensional array; see the simplify argument of sapply.
USE.NAMES    logical; use names if the first ...argument has names, or if it is a character vector,
    use that character vector as the names.

Details

mapply calls FUN for the values of ... (re-cycled to the length of the longest, unless any have length
    zero), followed by the arguments given in MoreArgs. The arguments in the call will be named if
    ... or MoreArgs are named.

Arguments with classes in ... will be accepted, and their subsetting and length methods will be
    used.

Value

A list, or for SIMPLIFY = TRUE, a vector, array or list.

See Also

sapply, after which mapply() is modelled.
outer, which applies a vectorized function to all combinations of two arguments.

Examples

mapply(rep, 1:4, 4:1)

mapply(rep, times = 1:4, x = 4:1)

mapply(rep, times = 1:4, MoreArgs = list(x = 42))
margin.table

**Description**

For a contingency table in array form, compute the sum of table entries for a given index.

**Usage**

```
margin.table(x, margin = NULL)
```

**Arguments**

- `x` an array
- `margin` index number (1 for rows, etc.)

**Details**

This is really just `apply(x, margin, sum)` packaged up for newbies, except that if `margin` has length zero you get `sum(x)`.

**Value**

The relevant marginal table. The class of `x` is copied to the output table, except in the summation case.

**Author(s)**

Peter Dalgaard

**See Also**

`prop.table` and `addmargins`.

**Examples**

```
m <- matrix(1:4, 2)
margin.table(m, 1)
margin.table(m, 2)
```
**Create a Matrix or a Vector**

**Description**

`mat.or.vec` creates an `nr` by `nc` zero matrix if `nc` is greater than 1, and a zero vector of length `nr` if `nc` equals 1.

**Usage**

```r
mat.or.vec(nr, nc)
```

**Arguments**

- `nr`, `nc` numbers of rows and columns.

**Examples**

```r
mat.or.vec(3, 1)
mat.or.vec(3, 2)
```

**Value Matching**

**Description**

`match` returns a vector of the positions of (first) matches of its first argument in its second.

`%in%` is a more intuitive interface as a binary operator, which returns a logical vector indicating if there is a match or not for its left operand.

**Usage**

```r
match(x, table, nomatch = NA_integer_, incomparables = NULL)
```

```r
x %in% table
```

**Arguments**

- `x` vector or `NULL`: the values to be matched. `Long vectors` are supported.
- `table` vector or `NULL`: the values to be matched against. `Long vectors` are not supported.
- `nomatch` the value to be returned in the case when no match is found. Note that it is coerced to integer.
- `incomparables` a vector of values that cannot be matched. Any value in `x` matching a value in this vector is assigned the `nomatch` value. For historical reasons, `FALSE` is equivalent to `NULL`. 
Details

%in% is currently defined as
```
"%in%" <- function(x, table) match(x, table, nomatch = 0) > 0
```

Factors, raw vectors and lists are converted to character vectors, and then \(x\) and \(table\) are coerced to a common type (the later of the two types in R’s ordering, logical < integer < numeric < complex < character) before matching. If incomparables has positive length it is coerced to the common type.

Matching for lists is potentially very slow and best avoided except in simple cases.

Exactly what matches what is to some extent a matter of definition. For all types, NA matches NA and no other value. For real and complex values, NaN values are regarded as matching any other NaN value, but not matching NA, where for complex \(x\), real and imaginary parts must match both (unless containing at least one NA).

Character strings will be compared as byte sequences if any input is marked as "bytes", and otherwise are regarded as equal if they are in different encodings but would agree when translated to UTF-8 (see Encoding).

That %in% never returns NA makes it particularly useful in if conditions.

Value

A vector of the same length as \(x\).

\(\text{match}\): An integer vector giving the position in \(table\) of the first match if there is a match, otherwise \(\text{nomatch}\).

If \(x[i]\) is found to equal \(table[j]\) then the value returned in the \(i\)-th position of the return value is \(j\), for the smallest possible \(j\). If no match is found, the value is \(\text{nomatch}\).

%in%: A logical vector, indicating if a match was located for each element of \(x\): thus the values are TRUE or FALSE and never NA.

References

See Also

\(\text{pmatch}\) and \(\text{charmatch}\) for (partial) string matching, \(\text{match.arg}\), etc for function argument matching. \(\text{findInterval}\) similarly returns a vector of positions, but finds numbers within intervals, rather than exact matches.

\(\text{is.element}\) for an S-compatible equivalent of %in%.

\(\text{unique}\) (and \(\text{duplicated}\)) are using the same definitions of “match” or “equality” as \(\text{match()}\), and these are less strict than \(==\), e.g., for NA and NaN in numeric or complex vectors, or for strings with different encodings, see also above.

Examples

```r
## The intersection of two sets can be defined via match():
## Simple version:
## intersect <- function(x, y) y[match(x, y, nomatch = 0)]
intersect # the R function in base is slightly more careful
intersect(1:10, 7:20)
```
match.arg

Argument Verification Using Partial Matching

Description

match.arg matches arg against a table of candidate values as specified by choices, where NULL means to take the first one.

Usage

match.arg(arg, choices, several.ok = FALSE)

Arguments

arg a character vector (of length one unless several.ok is TRUE) or NULL.
choices a character vector of candidate values
several.ok logical specifying if arg should be allowed to have more than one element.
Details

In the one-argument form `match.arg(arg)`, the choices are obtained from a default setting for the formal argument `arg` of the function from which `match.arg` was called. (Since default argument matching will set `arg` to choices, this is allowed as an exception to the ‘length one unless several.ok is TRUE’ rule, and returns the first element.)

Matching is done using `pmatch`, so `arg` may be abbreviated.

Value

The unabbreviated version of the exact or unique partial match if there is one; otherwise, an error is signalled if `several.ok` is false, as per default. When `several.ok` is true and more than one element of `arg` has a match, all unabbreviated versions of matches are returned.

See Also

`pmatch`, `match.fun`, `match.call`.

Examples

```r
require(stats)
## Extends the example for 'switch'
center <- function(x, type = c("mean", "median", "trimmed")) {
  type <- match.arg(type)
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
center(x, "t")    # Works
center(x, "med")  # Works
try(center(x, "m"))  # Error
stopifnot(identical(center(x), center(x, "mean")),
          identical(center(x, NULL), center(x, "mean")))

## Allowing more than one match:
match.arg(c("gauss", "rect", "ep"),
          c("gaussian", "epanechnikov", "rectangular", "triangular"),
          several.ok = TRUE)
```

Description

`match.call` returns a call in which all of the specified arguments are specified by their full names.

Usage

```r
match.call(definition = sys.function(sys.parent()),
           call = sys.call(sys.parent()),
           expand.dots = TRUE,
           envir = parent.frame(2L))
```
match.call

Arguments

definition a function, by default the function from which match.call is called. See details.
call an unevaluated call to the function specified by definition, as generated by call.
expand.dots logical. Should arguments matching ... in the call be included or left as a ... argument?
envir an environment, from which the ... in call are retrieved, if any.

Details

‘function’ on this help page means an interpreted function (also known as a ‘closure’): match.call does not support primitive functions (where argument matching is normally positional).

match.call is most commonly used in two circumstances:

• To record the call for later re-use: for example most model-fitting functions record the call as element call of the list they return. Here the default expand.dots = TRUE is appropriate.

• To pass most of the call to another function, often model.frame. Here the common idiom is that expand.dots = FALSE is used, and the ... element of the matched call is removed. An alternative is to explicitly select the arguments to be passed on, as is done in lm.

Calling match.call outside a function without specifying definition is an error.

Value

An object of class call.

References

See Also

sys.call() is similar, but does not expand the argument names; call, pmatch, match.arg, match.fun.

Examples

match.call(get, call("get", "abc", i = FALSE, p = 3))
## -> get(x = "abc", pos = 3, inherits = FALSE)
fun <- function(x, lower = 0, upper = 1) {
  structure((x - lower) / (upper - lower), CALL = match.call())
}
fun(4 * atan(1), u = pi)
match.fun

Extract a Function Specified by Name

Description

When called inside functions that take a function as argument, extract the desired function object while avoiding undesired matching to objects of other types.

Usage

match.fun(FUN, descend = TRUE)

Arguments

FUN item to match as function: a function, symbol or character string. See ‘Details’.
descend logical; control whether to search past non-function objects.

Details

match.fun is not intended to be used at the top level since it will perform matching in the parent of the caller.

If FUN is a function, it is returned. If it is a symbol (for example, enclosed in backquotes) or a character vector of length one, it will be looked up using get in the environment of the parent of the caller. If it is of any other mode, it is attempted first to get the argument to the caller as a symbol (using substitute twice), and if that fails, an error is declared.

If descend = TRUE, match.fun will look past non-function objects with the given name; otherwise if FUN points to a non-function object then an error is generated.

This is used in base functions such as apply, lapply, outer, and sweep.

Value

A function matching FUN or an error is generated.

Bugs

The descend argument is a bit of misnomer and probably not actually needed by anything. It may go away in the future.

It is impossible to fully foolproof this. If one attaches a list or data frame containing a length-one character vector with the same name as a function, it may be used (although namespaces will help).

Author(s)

Peter Dalgaard and Robert Gentleman, based on an earlier version by Jonathan Rougier.

See Also

match.arg, get
Examples

```r
# Same as get("\*"):
match.fun("\*")
# Overwrite outer with a vector
outer <- 1:5
try(match.fun(outer, descend = FALSE)) #-> Error: not a function
match.fun(outer) # finds it anyway
is.function(match.fun("outer")) # as well
```

---

**MathFun**

**Miscellaneous Mathematical Functions**

**Description**

abs(x) computes the absolute value of x, sqrt(x) computes the (principal) square root of x, \( \sqrt{x} \).

The naming follows the standard for computer languages such as C or Fortran.

**Usage**

```r
abs(x)
sqrt(x)
```

**Arguments**

- `x` a numeric or complex vector or array.

**Details**

These are internal generic primitive functions: methods can be defined for them individually or via the `Math` group generic. For complex arguments (and the default method), z, `abs(z) == Mod(z)` and `sqrt(z) == z^0.5`.

`abs(x)` returns an integer vector when x is integer or logical.

**S4 methods**

Both are S4 generic and members of the `Math` group generic.

**References**

**See Also**

`Arithmetic` for simple, `log` for logarithmic, `sin` for trigonometric, and `Special` for special mathematical functions.

`'plotmath'` for the use of `sqrt` in plot annotation.
Examples

```r
require(stats) # for spline
require(graphics)
xx <- -9:9
plot(xx, sqrt(abs(xx)), col = "red")
lines(spline(xx, sqrt(abs(xx)), n=101), col = "pink")
```

Description

Multiplies two matrices, if they are conformable. If one argument is a vector, it will be promoted to either a row or column matrix to make the two arguments conformable. If both are vectors of the same length, it will return the inner product (as a matrix).

Usage

```r
x %*% y
```

Arguments

- `x, y` numeric or complex matrices or vectors.

Details

When a vector is promoted to a matrix, its names are not promoted to row or column names, unlike `as.matrix`.

Promotion of a vector to a 1-row or 1-column matrix happens when one of the two choices allows `x` and `y` to get conformable dimensions.

This operator is S4 generic but not S3 generic. S4 methods need to be written for a function of two arguments named `x` and `y`.

Value

A double or complex matrix product. Use `drop` to remove dimensions which have only one level.

Note

The propagation of NaN/Inf values, precision, and performance of matrix products can be controlled by `options("matprod")`.

References

See Also

For matrix crossproducts, `crossprod()` and `tcrossprod()` are typically preferable. `matrix`, `Arithmetic`, `diag`.
Examples

```r
x <- 1:4
(z <- x %*% x) # scalar ("inner") product (1 x 1 matrix)
drop(z) # as scalar

y <- diag(x)
z <- matrix(1:12, ncol = 3, nrow = 4)
y %*% z
y %*% x
x %*% z
```

matrix  

Description

matrix creates a matrix from the given set of values.
as.matrix attempts to turn its argument into a matrix.
is.matrix tests if its argument is a (strict) matrix.

Usage

```r
matrix(data = NA, nrow = 1, ncol = 1, byrow = FALSE,
dimnames = NULL)
as.matrix(x, ...)
## S3 method for class 'data.frame'
as.matrix(x, rownames.force = NA, ...)
is.matrix(x)
```

Arguments

data an optional data vector (including a list or expression vector). Non-atomic classed R objects are coerced by as.vector and all attributes discarded.
nrow the desired number of rows.
col the desired number of columns.
byrow logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
dimnames A dimnames attribute for the matrix: NULL or a list of length 2 giving the row and column names respectively. An empty list is treated as NULL, and a list of length one as row names. The list can be named, and the list names will be used as names for the dimensions.
x an R object.
... additional arguments to be passed to or from methods.
rownames.force logical indicating if the resulting matrix should have character (rather than NULL) rownames. The default, NA, uses NULL rownames if the data frame has ‘automatic’ row.names or for a zero-row data frame.
Details

If one of nrow or ncol is not given, an attempt is made to infer it from the length of data and the other parameter. If neither is given, a one-column matrix is returned.

If there are too few elements in data to fill the matrix, then the elements in data are recycled. If data has length zero, NA of an appropriate type is used for atomic vectors (0 for raw vectors) and NULL for lists.

is.matrix returns TRUE if x is a vector and has a "dim" attribute of length 2) and FALSE otherwise. Note that a data.frame is not a matrix by this test. The function is generic: you can write methods to handle specific classes of objects, see InternalMethods.

as.matrix is a generic function. The method for data frames will return a character matrix if there is only atomic columns and any non-(numeric/logical/complex) column, applying as.vector to factors and format to other non-character columns. Otherwise, the usual coercion hierarchy (logical < integer < double < complex) will be used, e.g., all-logical data frames will be coerced to a logical matrix, mixed logical-integer will give a integer matrix, etc.

The default method for as.matrix calls as.vector(x), and hence e.g. coerces factors to character vectors.

When coercing a vector, it produces a one-column matrix, and promotes the names (if any) of the vector to the rownames of the matrix.

is.matrix is a primitive function.

The print method for a matrix gives a rectangular layout with dimnames or indices. For a list matrix, the entries of length not one are printed in the form ‘integer,7’ indicating the type and length.

Note

If you just want to convert a vector to a matrix, something like

```r
dim(x) <- c(nx, ny)
dimnames(x) <- list(row_names, col_names)
```

will avoid duplicating x.

References

See Also

data.matrix, which attempts to convert to a numeric matrix.

A matrix is the special case of a two-dimensional array.

Examples

```r
is.matrix(as.matrix(1:10))
!is.matrix(warpbreaks) # data.frame, NOT matrix!
warpbreaks[1:10,]
as.matrix(warpbreaks[1:10,]) # using as.matrix.data.frame(.) method

# Example of setting row and column names
mdat <- matrix(c(1,2,3, 11,12,13), nrow = 2, ncol = 3, byrow = TRUE,
```
maxCol

Find Maximum Position in Matrix

dimnames = list(c("row1", "row2"),
               c("C.1", "C.2", "C.3"))
mdat

Description
Find the maximum position for each row of a matrix, breaking ties at random.

Usage
max.col(m, ties.method = c("random", "first", "last"))

Arguments
m numerical matrix
ties.method a character string specifying how ties are handled, "random" by default; can be abbreviated; see ‘Details’.

Details
When ties.method = "random", as per default, ties are broken at random. In this case, the determination of a tie assumes that the entries are probabilities: there is a relative tolerance of $10^{-5}$, relative to the largest (in magnitude, omitting infinity) entry in the row.
If ties.method = "first", max.col returns the column number of the first of several maxima in every row, the same as unname(apply(m, 1, which.max)). Correspondingly, ties.method = "last" returns the last of possibly several indices.

Value
index of a maximal value for each row, an integer vector of length nrow(m).

References

See Also
which.max for vectors.

Examples

table(mc <- max.col(swiss))  # mostly "1" and "5", 5 x "2" and once "4"
swiss[unique(print(mr <- max.col(t(swiss)))) , ]  # 3 33 45 45 33 6

set.seed(1)  # reproducible example:
(mm <- rbind(x = round(2*stats::runif(12)),
            y = round(5*stats::runif(12)),
            z = round(8*stats::runif(12))))

## Not run:
mean

## End(Not run)
## column indices of all row maxima :
utils::str(lapply(1:3, function(i) which(mm[i,] == max(mm[i,]))))
max.col(mm) ; max.col(mm) # "random"
max.col(mm, "first") # -> 4 6 5
max.col(mm, "last") # -> 7 9 11

### Description

Generic function for the (trimmed) arithmetic mean.

### Usage

```r
mean(x, ...)```

### Arguments

- **x**: An R object. Currently there are methods for numeric/logical vectors and `date`, `date-time` and `time interval` objects. Complex vectors are allowed for `trim = 0`, only.
- **trim**: the fraction (0 to 0.5) of observations to be trimmed from each end of `x` before the mean is computed. Values of `trim` outside that range are taken as the nearest endpoint.
- **na.rm**: a logical value indicating whether NA values should be stripped before the computation proceeds.
- **...**: further arguments passed to or from other methods.

### Value

If `trim` is zero (the default), the arithmetic mean of the values in `x` is computed, as a numeric or complex vector of length one. If `x` is not logical (coerced to numeric), numeric (including integer) or complex, `NA_real_` is returned, with a warning.

If `trim` is non-zero, a symmetrically trimmed mean is computed with a fraction of `trim` observations deleted from each end before the mean is computed.

### References

memCompress

See Also
weighted.mean, mean.POSIXct, colMeans for row and column means.

Examples
x <- c(0:10, 50)
xm <- mean(x)
c(xm, mean(x, trim = 0.10))

memCompress
In-memory Compression and Decompression

Description
In-memory compression or decompression for raw vectors.

Usage
memCompress(from, type = c("gzip", "bzip2", "xz", "none"))
memDecompress(from,
    type = c("unknown", "gzip", "bzip2", "xz", "none"),
    asChar = FALSE)

Arguments
from A raw vector. For memCompress a character vector will be converted to a raw vector with character strings separated by "\n".
type character string, the type of compression. May be abbreviated to a single letter, defaults to the first of the alternatives.
asChar logical: should the result be converted to a character string?

Details
type = "none" passes the input through unchanged, but may be useful if type is a variable.
type = "unknown" attempts to detect the type of compression applied (if any): this will always succeed for bzip2 compression, and will succeed for other forms if there is a suitable header. It will auto-detect the ‘magic’ header ("\x1f\x8b") added to files by the gzip program (and to files written by gzfile), but memCompress does not add such a header.
bzip2 compression always adds a header ("BZh").
Compressing with type = "xz" is equivalent to compressing a file with xz -9e (including adding the ‘magic’ header): decompression should cope with the contents of any file compressed with xz version 4.999 and some versions of lzma. There are other versions, in particular ‘raw’ streams, that are not currently handled.
All the types of compression can expand the input: for "gzip" and "bzip2" the maximum expansion is known and so memCompress can always allocate sufficient space. For "xz" it is possible (but extremely unlikely) that compression will fail if the output would have been too large.
Memory

Value

A raw vector or a character string (if asChar = TRUE).

See Also

connections.

extSoftVersion for the versions of the zlib, bzip2 and xz libraries in use.

Examples

```r
.txt <- readLines(file.path(R.home("doc"), "COPYING"))
sum(nchar(.txt))
.txt.gz <- memCompress(.txt, "g")
length(.txt.gz)
.txt2 <- strsplit(memDecompress(.txt.gz, "g", asChar = TRUE), "\n")[[1]]
stopifnot(identical(.txt, .txt2))
.txt.bz2 <- memCompress(.txt, "b")
length(.txt.bz2)
# can auto-detect bzip2:
.txt3 <- strsplit(memDecompress(.txt.bz2, asChar = TRUE), "\n")[[1]]
stopifnot(identical(.txt, .txt3))
# xz compression is only worthwhile for large objects
.txt.xz <- memCompress(.txt, "x")
length(.txt.xz)
.txt3 <- strsplit(memDecompress(.txt.xz, asChar = TRUE), "\n")[[1]]
stopifnot(identical(.txt, .txt3))
```

Description

How R manages its workspace.

Details

R has a variable-sized workspace. There are (rarely-used) command-line options to control its minimum size, but no longer any to control the maximum size.

R maintains separate areas for fixed and variable sized objects. The first of these is allocated as an array of cons cells (Lisp programmers will know what they are, others may think of them as the building blocks of the language itself, parse trees, etc.), and the second are thrown on a heap of 'Vcells' of 8 bytes each. Each cons cell occupies 28 bytes on a 32-bit build of R, (usually) 56 bytes on a 64-bit build.

The default values are (currently) an initial setting of 350k cons cells and 6Mb of vector heap. Note that the areas are not actually allocated initially: rather these values are the sizes for triggering garbage collection. These values can be set by the command line options ‘--min-nsize’ and
‘--min-vsize’ (or if they are not used, the environment variables R_NSIZE and R_VSIZE) when \texttt{R} is started. Thereafter \texttt{R} will grow or shrink the areas depending on usage, never decreasing below the initial values.

How much time \texttt{R} spends in the garbage collector will depend on these initial settings and on the trade-off the memory manager makes, when memory fills up, between collecting garbage to free up unused memory and growing these areas. The strategy used for growth can be specified by setting the environment variable \texttt{R_GC_MEM_GROW} to an integer value between 0 and 3. This variable is read at start-up. Higher values grow the heap more aggressively, thus reducing garbage collection time but using more memory.

You can find out the current memory consumption (the heap and cons cells used as numbers and megabytes) by typing \texttt{gc()} at the \texttt{R} prompt. Note that following \texttt{gcinfo(TRUE)}, automatic garbage collection always prints memory use statistics.

The command-line option ‘--max-ppsize’ controls the maximum size of the pointer protection stack. This defaults to 50000, but can be increased to allow deep recursion or large and complicated calculations to be done. \textit{Note} that parts of the garbage collection process goes through the full reserved pointer protection stack and hence becomes slower when the size is increased. Currently the maximum value accepted is 500000.

\begin{center}
\begin{tabular}{ll}
\textbf{Memory-limits} & \textbf{Memory Limits in R} \\
\end{tabular}
\end{center}

\textbf{Description}

\texttt{R} holds objects it is using in virtual memory. This help file documents the current design limitations on large objects: these differ between 32-bit and 64-bit builds of \texttt{R}.

\textbf{Details}

Currently \texttt{R} runs on 32- and 64-bit operating systems, and most 64-bit OSes (including Linux, Solaris, Windows and macOS) can run either 32- or 64-bit builds of \texttt{R}. The memory limits depends mainly on the build, but for a 32-bit build of \texttt{R} on Windows they also depend on the underlying OS version.

\texttt{R} holds all objects in virtual memory, and there are limits based on the amount of memory that can be used by all objects:

\begin{itemize}
\item There may be limits on the size of the heap and the number of cons cells allowed – see \texttt{Memory} – but these are usually not imposed.
\item There is a limit on the (user) address space of a single process such as the \texttt{R} executable. This is system-specific, and can depend on the executable.
\item The environment may impose limitations on the resources available to a single process: Windows’ versions of \texttt{R} do so directly.
\end{itemize}
Error messages beginning cannot allocate vector of size indicate a failure to obtain memory, either because the size exceeded the address-space limit for a process or, more likely, because the system was unable to provide the memory. Note that on a 32-bit build there may well be enough free memory available, but not a large enough contiguous block of address space into which to map it.

There are also limits on individual objects. The storage space cannot exceed the address limit, and if you try to exceed that limit, the error message begins cannot allocate vector of length. The number of bytes in a character string is limited to $2^{31} - 1 \approx 2 \times 10^9$, which is also the limit on each dimension of an array.

Unix

The address-space limit is system-specific: 32-bit OSes imposes a limit of no more than 4Gb: it is often 3Gb. Running 32-bit executables on a 64-bit OS will have similar limits: 64-bit executables will have an essentially infinite system-specific limit (e.g., 128Tb for Linux on x86_64 cpus).

See the OS/shell’s help on commands such as limit or ulimit for how to impose limitations on the resources available to a single process. For example a bash user could use

```
ulimit -t 600 -v 4000000
```

whereas a csh user might use

```
limit cputime 10m
limit vmemoryuse 4096m
```

to limit a process to 10 minutes of CPU time and (around) 4Gb of virtual memory. (There are other options to set the RAM in use, but they are not generally honoured.)

Windows

The address-space limit is 2Gb under 32-bit Windows unless the OS’s default has been changed to allow more (up to 3Gb). See https://www.microsoft.com/whdc/system/platform/server/PAE/PAEmem.mspx and https://msdn.microsoft.com/en-us/library/bb613473(VS.85).aspx. Under most 64-bit versions of Windows the limit for a 32-bit build of R is 4Gb: for the oldest ones it is 2Gb. The limit for a 64-bit build of R (imposed by the OS) is 8Tb.

It is not normally possible to allocate as much as 2Gb to a single vector in a 32-bit build of R even on 64-bit Windows because of preallocations by Windows in the middle of the address space.

Under Windows, R imposes limits on the total memory allocation available to a single session as the OS provides no way to do so: see memory.size and memory.limit.

See Also

object.size(a) for the (approximate) size of R object a.
memory.profile  Profile the Usage of Cons Cells

Description
Lists the usage of the cons cells by SEXPREC type.

Usage
memory.profile()

Details
The current types and their uses are listed in the include file ‘Rinternals.h’.

Value
A vector of counts, named by the types. See typeof for an explanation of types.

See Also
gc for the overall usage of cons cells. Rprofmem and tracemem allow memory profiling of specific code or objects, but need to be enabled at compile time.

Examples
memory.profile()

merge  Merge Two Data Frames

Description
Merge two data frames by common columns or row names, or do other versions of database join operations.

Usage
merge(x, y, ...)

## Default S3 method:
merge(x, y, ...)

## S3 method for class 'data.frame'
merge(x, y, by = intersect(names(x), names(y)),
    by.x = by, by.y = by, all = FALSE, all.x = all, all.y = all,
    sort = TRUE, suffixes = c(".x",".y"),
    incomparables = NULL, ...)

merge

Arguments

x, y data frames, or objects to be coerced to one.
by, by.x, by.y specifications of the columns used for merging. See ‘Details’.
all logical; all = L is shorthand for all.x = L and all.y = L, where L is either TRUE or FALSE.
all.x logical; if TRUE, then extra rows will be added to the output, one for each row in x that has no matching row in y. These rows will have NAs in those columns that are usually filled with values from y. The default is FALSE, so that only rows with data from both x and y are included in the output.
all.y logical; analogous to all.x.
sort logical. Should the result be sorted on the by columns?
suffixes a character vector of length 2 specifying the suffixes to be used for making unique the names of columns in the result which are not used for merging (appearing in by etc).
incomparables values which cannot be matched. See match. This is intended to be used for merging on one column, so these are incomparable values of that column.
...

Details

merge is a generic function whose principal method is for data frames: the default method coerces its arguments to data frames and calls the "data.frame" method.

By default the data frames are merged on the columns with names they both have, but separate specifications of the columns can be given by by.x and by.y. The rows in the two data frames that match on the specified columns are extracted, and joined together. If there is more than one match, all possible matches contribute one row each. For the precise meaning of ‘match’, see match.

Columns to merge on can be specified by name, number or by a logical vector: the name "row.names" or the number 0 specifies the row names. If specified by name it must correspond uniquely to a named column in the input.

If by or both by.x and by.y are of length 0 (a length zero vector or NULL), the result, r, is the Cartesian product of x and y, i.e., dim(r) = c(nrow(x)*nrow(y), ncol(x) + ncol(y)).

If all.x is true, all the non matching cases of x are appended to the result as well, with NA filled in the corresponding columns of y; analogously for all.y.

If the columns in the data frames not used in merging have any common names, these have suffixes (".x" and ".y" by default) appended to try to make the names of the result unique. If this is not possible, an error is thrown.

The complexity of the algorithm used is proportional to the length of the answer.

In SQL database terminology, the default value of all = FALSE gives a natural join, a special case of an inner join. Specifying all.x = TRUE gives a left (outer) join, all.y = TRUE a right (outer) join, and both (all = TRUE a (full) outer join. DBMSes do not match NULL records, equivalent to incomparables = NA in R.

Value

A data frame. The rows are by default lexicographically sorted on the common columns, but for sort = FALSE are in an unspecified order. The columns are the common columns followed by the remaining columns in x and then those in y. If the matching involved row names, an extra character column called Row.names is added at the left, and in all cases the result has ‘automatic’ row names.
Note

This is intended to work with data frames with vector-like columns: some aspects work with data frames containing matrices, but not all.

Currently long vectors are not accepted for inputs, which are thus restricted to less than 2^31 rows. That restriction also applies to the result for 32-bit platforms.

See Also

data.frame, by, cbind.

dendrogram for a class which has a merge method.

Examples

```r
## use character columns of names to get sensible sort order
authors <- data.frame(
  surname = I(c("Tukey", "Venables", "Tierney", "Ripley", "McNeil")),
  nationality = c("US", "Australia", "US", "UK", "Australia"),
  deceased = c("yes", rep("no", 4))
)
books <- data.frame(
  name = I(c("Tukey", "Venables", "Tierney", "Ripley", "Ripley", "McNeil", "R Core")),
  other.author = c(NA, "Ripley", NA, NA, NA, NA, "Venables & Smith")
)

(m1 <- merge(authors, books, by.x = "surname", by.y = "name"))
(m2 <- merge(books, authors, by.x = "name", by.y = "surname"))
stopifnot(as.character(m1[, 1]) == as.character(m2[, 1]),
  all.equal(m1[, -1], m2[, -1][ names(m1)[-1] ]),
  dim(merge(m1, m2, by = integer(0))) == c(36, 10))

## "R core" is missing from authors and appears only here:
merge(authors, books, by.x = "surname", by.y = "name", all = TRUE)

## example of using 'incomparables'
x <- data.frame(k1 = c(NA,NA,3,4,5), k2 = c(1,NA,NA,4,5), data = 1:5)
y <- data.frame(k1 = c(NA,2,NA,4,5), k2 = c(NA,NA,3,4,5), data = 1:5)
merge(x, y, by = c("k1","k2")) # NA's match
merge(x, y, by = "k1") # NA's match, so 6 rows
merge(x, y, by = "k2", incomparables = NA) # 2 rows
```

---

### Diagnostic Messages

<table>
<thead>
<tr>
<th>message</th>
<th>Description</th>
</tr>
</thead>
</table>

Generate a diagnostic message from its arguments.
Usage

```r
message(..., domain = NULL, appendLF = TRUE)
suppressMessages(expr)

packageStartupMessage(..., domain = NULL, appendLF = TRUE)
suppressPackageStartupMessages(expr)

.makeMessage(..., domain = NULL, appendLF = FALSE)
```

Arguments

- `...`: zero or more objects which can be coerced to character (and which are pasted together with no separator) or (for `message` only) a single condition object.
- `domain`: see `gettext`. If `NA`, messages will not be translated, see also the note in `stop`.
- `appendLF`: logical: should messages given as a character string have a newline appended?
- `expr`: expression to evaluate.

Details

`message` is used for generating ‘simple’ diagnostic messages which are neither warnings nor errors, but nevertheless represented as conditions. Unlike warnings and errors, a final newline is regarded as part of the message, and is optional. The default handler sends the message to the `stderr()` connection.

If a condition object is supplied to `message` it should be the only argument, and further arguments will be ignored, with a warning.

While the message is being processed, a `muffleMessage` restart is available.

`suspendMessages` evaluates its expression in a context that ignores all ‘simple’ diagnostic messages.

`packageStartupMessage` is a variant whose messages can be suppressed separately by `suppressPackageStartupMessages`. (They are still messages, so can be suppressed by `suspendMessages`.)

`.makeMessage` is a utility used by `message`, `warning` and `stop` to generate a text message from the `...` arguments by possible translation (see `gettext`) and concatenation (with no separator).

See Also

- `warning` and `stop` for generating warnings and errors; `conditions` for condition handling and recovery.
- `gettext` for the mechanisms for the automated translation of text.

Examples

```r
message("ABC", "DEF")
suppressMessages(message("ABC"))

testit <- function() {
    message("testing package startup messages")
    packageStartupMessage("initializing ...", appendLF = FALSE)
    Sys.sleep(1)
    packageStartupMessage(" done")
}
Description

missing can be used to test whether a value was specified as an argument to a function.

Usage

missing(x)

Arguments

x a formal argument.

Details

missing(x) is only reliable if x has not been altered since entering the function: in particular it will always be false after x <- match.arg(x).

The example shows how a plotting function can be written to work with either a pair of vectors giving x and y coordinates of points to be plotted or a single vector giving y values to be plotted against their indices.

Currently missing can only be used in the immediate body of the function that defines the argument, not in the body of a nested function or a local call. This may change in the future.

This is a ‘special’ primitive function: it must not evaluate its argument.

References

See Also

substitute for argument expression; NA for missing values in data.

Examples

myplot <- function(x, y) {
  if(missing(y)) {
    y <- x
    x <- 1:length(y)
  }
  plot(x, y)
}
The (Storage) Mode of an Object

Description
Get or set the type or storage mode of an object.

Usage
\[
\text{mode}(x) \\
\text{mode}(x) \leftarrow \text{value} \\
\text{storage.mode}(x) \\
\text{storage.mode}(x) \leftarrow \text{value}
\]

Arguments
\[
x \quad \text{any R object.} \\
\text{value} \quad \text{a character string giving the desired mode or ‘storage mode’ (type) of the object.}
\]

Details
Both \text{mode} and \text{storage.mode} return a character string giving the (storage) mode of the object — often the same — both relying on the output of \text{typeof}(x), see the example below.

\text{mode}(x) \leftarrow \"newmode\" \text{ changes the mode of object } x \text{ to newmode. This is only supported if there is an appropriate as.newmode function, for example \"logical\", \"integer\", \"double\", \"complex\", \"raw\", \"character\", \"list\", \"expression\", \"name\", \"symbol\" and \"function\". Attributes are preserved (but see below).

\text{storage.mode}(x) \leftarrow \"newmode\" \text{ is a more efficient primitive version of } \text{mode} \leftarrow \text{, which works for \"newmode\" which is one of the internal types (see } \text{typeof}, \text{ but not for \"single\". Attributes are preserved.}

As storage mode \"single\" is only a pseudo-mode in R, it will not be reported by \text{mode} or \text{storage.mode}: use \text{attr}(\text{object, \"Csingle\") \text{ to examine this. However, } \text{mode} \leftarrow \text{ can be used to set the mode to \"single\", which sets the real mode to \"double\" and the \"Csingle\" attribute to \text{TRUE}. Setting any other mode will remove this attribute.}

Note (in the examples below) that some \text{calls} have mode \("\text{" which is S compatible.

Mode names
Modes have the same set of names as types (see \text{typeof}) except that

- types \"integer\" and \"double\" are returned as \"numeric\".
- types \"special\" and \"builtin\" are returned as \"function\".
- type \"symbol\" is called mode \"name\".
- type \"language\" is returned as \"(\" or \"call\".

References
NA

‘Not Available’ / Missing Values

Description

NA is a logical constant of length 1 which contains a missing value indicator. NA can be coerced to any other vector type except raw. There are also constants NA_integer_, NA_real_, NA_complex_ and NA_character_ of the other atomic vector types which support missing values: all of these are reserved words in the R language.

The generic function is.na indicates which elements are missing.

The generic function is.na<- sets elements to NA.

The generic function anyNA implements any(is.na(x)) in a possibly faster way (especially for atomic vectors).

Usage

NA
is.na(x)
anyNA(x, recursive = FALSE)

## S3 method for class 'data.frame'
is.na(x)

is.na(x) <- value
Arguments

- **x**: an R object to be tested: the default method for `is.na` handles atomic vectors, lists and pairlists; that for anyNA also handles NULL.
- **recursive**: logical: should anyNA be applied recursively to lists and pairlists?
- **value**: a suitable index vector for use with `x`.

Details

The `NA` of character type is distinct from the string "NA". Programmers who need to specify an explicit missing string should use `NA_character_` (rather than "NA") or set elements to `NA` using `is.na<-`.

`is.na` and anyNA are generic: you can write methods to handle specific classes of objects, see `InternalMethods`.

Function `is.na<-` may provide a safer way to set missingness. It behaves differently for factors, for example.

Numerical computations using `NA` will normally result in `NA`: a possible exception is where `NaN` is also involved, in which case either might result (which may depend on the R platform). Logical computations treat `NA` as a missing TRUE/FALSE value, and so may return TRUE or FALSE if the expression does not depend on the `NA` operand.

The default method for anyNA handles atomic vectors without a class and NULL. It calls `any(is.na(x)` on objects with classes and for `recursive = FALSE`, on lists and pairlists.

Value

The default method for `is.na` applied to an atomic vector returns a logical vector of the same length as its argument `x`, containing TRUE for those elements marked `NA` or, for numeric or complex vectors, `NaN`, and FALSE otherwise. (A complex value is regarded as `NA` if either its real or imaginary part is `NA` or `NaN`.) `dim`, `dimnames` and `names` attributes are copied to the result.

The default methods also work for lists and pairlists:

For `is.na`, elementwise the result is false unless that element is a length-one atomic vector and the single element of that vector is regarded as `NA` or `NaN` (note that any `is.na` method for the class of the element is ignored).

`anyNA(recursive = FALSE)` works the same way as `is.na`; `anyNA(recursive = TRUE)` applies `anyNA` (with method dispatch) to each element.

The data frame method for `is.na` returns a logical matrix with the same dimensions as the data frame, and with dimnames taken from the row and column names of the data frame.

`anyNA(NULL)` is false: `is.na(NULL)` is `logical(0)` with a warning.

`na.action`, `na.omit`, `na.fail` on how methods can be tuned to deal with missing values.
Examples

```r
is.na(c(1, NA)) #> FALSE TRUE
is.na(paste(c(1, NA))) #> FALSE FALSE

(xx <- c(0:4))
is.na(xx) <- c(2, 4)
xx #> 0 NA 2 NA 4
anyNA(xx) # TRUE

# Some logical operations do not return NA
(c(TRUE, FALSE) & NA)
c(TRUE, FALSE) | NA
```

```r
## Measure speed difference in a favourable case:
## the difference depends on the platform, on most ca 3x.
x <- 1:10000; x[5000] <- NaN # coerces x to be double
if(require("microbenchmark")) { # does not work reliably on all platforms
  print(microbenchmark(any(is.na(x)), anyNA(x)))
} else {
  nSim <- 2^13
  print(rbind(is.na = system.time(replicate(nSim, any(is.na(x)))),
             anyNA = system.time(replicate(nSim, anyNA(x)))))
}
```

```r
## anyNA() can work recursively with list(s):
LL <- list(1:5, c(NA, 5:8), c("A","NA"), c("a", NA_character_))
L2 <- LL[c(1,3)]
sapply(LL, anyNA); c(anyNA(LL), anyNA(LL, TRUE))
sapply(L2, anyNA); c(anyNA(L2), anyNA(L2, TRUE))
```

```r
## ... lists, and hence data frames, too:
dN <- dd <- USJudgeRatings; dN[3,6] <- NA
anyNA(dd) # FALSE
anyNA(dN) # TRUE
```

---

### Names and Symbols

**Description**

A ‘name’ (also known as a ‘symbol’) is a way to refer to R objects by name (rather than the value of the object, if any, bound to that name).

`as.name` and `as.symbol` are identical: they attempt to coerce the argument to a name.

`is.symbol` and the identical `is.name` return `TRUE` or `FALSE` depending on whether the argument is a name or not.

**Usage**

```r
as.symbol(x)
is.symbol(x)
```
as.name(x)

is.name(x)

Arguments

x object to be coerced or tested.

Details

Names are limited to 10,000 bytes (and were to 256 bytes in versions of R before 2.13.0).

as.name first coerces its argument internally to a character vector (so methods for as.character are not used). It then takes the first element and provided it is not "", returns a symbol of that name (and if the element is NA_character_, the name is \`NA\`).

as.name is implemented as as.vector(x, "symbol"), and hence will dispatch methods for the generic function as.vector.

is.name and is.symbol are primitive functions.

Value

For as.name and as.symbol, an R object of type "symbol" (see typeof).

For is.name and is.symbol, a length-one logical vector with value TRUE or FALSE.

Note

The term ‘symbol’ is from the LISP background of R, whereas ‘name’ has been the standard S term for this.

The Names of an Object

Description
Functions to get or set the names of an object.

Usage
\[
\begin{align*}
\text{names}(x) \\
\text{names}(x) \leftarrow \text{value}
\end{align*}
\]

Arguments
\[
\begin{align*}
x & \quad \text{an \texttt{R} object.} \\
\text{value} & \quad \text{a character vector of up to the same length as } x, \text{ or } \texttt{NULL}.
\end{align*}
\]

Details
names is a generic accessor function, and names<- is a generic replacement function. The default methods get and set the “names” attribute of a vector (including a list) or pairlist.

For an environment env, names(env) gives the names of the corresponding list, i.e., names(as.list(env, all.names = TRUE)) which are also given by ls(env, all.names = TRUE, sorted = FALSE). If the environment is used as a hash table, names(env) are its “keys”.

If value is shorter than x, it is extended by character NAs to the length of x.

It is possible to update just part of the names attribute via the general rules: see the examples. This works because the expression there is evaluated as z <- "names<-"(z, "[<-"(names(z), 3, "c2"))

The name "" is special: it is used to indicate that there is no name associated with an element of a (atomic or generic) vector. Subscripting by "" will match nothing (not even elements which have no name).

A name can be character NA, but such a name will never be matched and is likely to lead to confusion.
Both are primitive functions.

Value
For names, NULL or a character vector of the same length as x. (NULL is given if the object has no names, including for objects of types which cannot have names.) For an environment, the length is the number of objects in the environment but the order of the names is arbitrary.

For names<-, the updated object. (Note that the value of names(x) <- value is that of the assignment, value, not the return value from the left-hand side.)

Note
For vectors, the names are one of the attributes with restrictions on the possible values. For pairlists, the names are the tags and converted to and from a character vector.

For a one-dimensional array the names attribute really is dimnames[[1]].

Formally classed aka “S4” objects typically have slotNames() (and no names()).
nargs

The Number of Arguments to a Function

Description

When used inside a function body, nargs returns the number of arguments supplied to that function, including positional arguments left blank.

Usage

nargs()

Details

The count includes empty (missing) arguments, so that foo(x,,z) will be considered to have three arguments (see ‘Examples’). This can occur in rather indirect ways, so for example x[] might dispatch a call to `\[.some_method\](x,) which is considered to have two arguments.

This is a primitive function.
nchar

References

See Also

`args`, `formals` and `sys.call`.

Examples

```r
> tst <- function(a, b = 3, ...) { nargs() }
> tst() # 0
> tst(clicketyclack) # 1 (even non-existing)
> tst(c1, a2, rr3) # 3

> foo <- function(x, y, z, w) {
>   cat("call was ", deparse(match.call()), "\n", sep = "")
>   nargs()
> }
> foo()     # 0
> foo(, , 3) # 3
> foo(z = 3) # 1, even though this is the same call
> nargs()   # not really meaningful
```

nchar

Count the Number of Characters (or Bytes or Width)

Description

`nchar` takes a character vector as an argument and returns a vector whose elements contain the sizes of the corresponding elements of `x`.

`nzchar` is a fast way to find out if elements of a character vector are non-empty strings.

Usage

```r
nchar(x, type = "chars", allowNA = FALSE, keepNA = NA)

nzchar(x, keepNA = FALSE)
```

Arguments

- `x` character vector, or a vector to be coerced to a character vector. Giving a factor is an error.
- `type` character string: partial matching to one of c("bytes", "chars", "width"). See 'Details'.
- `allowNA` logical: should NA be returned for invalid multibyte strings or "bytes"-encoded strings (rather than throwing an error)?
- `keepNA` logical: should NA be returned where ever x is NA? If false, `nchar()` returns 2, as that is the number of printing characters used when strings are written to output, and `nzchar()` is TRUE. The default for `nchar()` is TRUE unless type is "width". Used to be (implicitly) hard coded to FALSE in R versions ≤ 3.2.0.
**Details**

The ‘size’ of a character string can be measured in one of three ways (corresponding to the type argument):

- **bytes**  The number of bytes needed to store the string (plus in C a final terminator which is not counted).
- **chars**  The number of human-readable characters.
- **width**  The number of columns **cat** will use to print the string in a monospaced font. The same as **chars** if this cannot be calculated.

These will often be the same, and almost always will be in single-byte locales (but note how type determines the default for **keepNA**). There will be differences between the first two with multibyte character sequences, e.g. in UTF-8 locales.

The internal equivalent of the default method of **as.character** is performed on **x** (so there is no method dispatch). If you want to operate on non-vector objects passing them through **deparse** first will be required.

**Value**

For **nchar**, an integer vector giving the sizes of each element. For missing values (i.e., **NA**, i.e., **NA_character_**), **nchar()** returns **NA_integer_** if **keepNA** is true, and 2, the number of printing characters, if false.

- **type = "width"** gives (an approximation to) the number of columns used in printing each element in a terminal font, taking into account double-width, zero-width and ‘composing’ characters.

If **allowNA = TRUE** and an element is detected as invalid in a multi-byte character set such as UTF-8, its number of characters and the width will be **NA**. Otherwise the number of characters will be non-negative, so **!is.na(nchar(x, "chars", TRUE))** is a test of validity.

A character string marked with “bytes” encoding (see **Encoding**) has a number of bytes, but neither a known number of characters nor a width, so the latter two types are **NA** if **allowNA = TRUE**, otherwise an error.

Names, dims and dimnames are copied from the input.

For **nzchar**, a logical vector of the same length as **x**, true if and only if the element has non-zero length; if the element is **NA**, **nzchar()** is true when **keepNA** is false, as by default, and **NA** otherwise.

**Note**

This does **not** by default give the number of characters that will be used to **print()** the string. Use **encodeString** to find that. Where character strings have been marked as UTF-8, the number of characters and widths will be computed in UTF-8, even though printing may use escapes such as ‘\u2642’ in a non-UTF-8 locale.

The concept of ‘width’ is a slippery one even in a monospaced font. Some human languages have the concept of **combining** characters, in which two or more characters are rendered together: an example would be "y\u306", which is two characters of width one: combining characters are given width zero, and there are other zero-width characters such as the zero-width space “\u200b”.

Some East Asian languages have ‘wide’ characters, ideographs which are conventionally printed across two columns when mixed with ASCII and other ‘narrow’ characters in those languages. The problem is that whether a computer prints wide characters over two or one columns depends on the font, with it not being uncommon to use two columns in a font intended for East Asian users and a single column in a ‘Western’ font. Unicode has encodings for ‘fullwidth’ versions of ASCII characters and ‘halfwidth’ versions of Katakana (Japanese) and Hangul (Korean) characters. Then
there is the 'East Asian Ambiguous class' (Greek, Cyrillic, signs, some accented Latin chars, etc),
for which the historical practice was to use two columns in East Asia and one elsewhere. The width
quoted by nchar for characters in that class (and some others) depends on the locale, being one
except in some East Asian locales on some OSes (notably Windows).

Control characters are given width zero.

Examples

x <- c("asfef", "qwerty", "yuiop[", "b", "stuff.blah.yech")
nchar(x)
  # 5 6 6 1 15
nchar(deparse(mean))
  # 18 17 <- unless mean differs from base::mean

x[3] <- NA; x
nchar(x, keepNA= TRUE) # 5 6 NA 1 15
nchar(x, keepNA=FALSE) # 5 6 2 1 15
stopifnot(identical(nchar(x ), nchar(x, keepNA= TRUE)),
          identical(nchar(x, "w"), nchar(x, keepNA=FALSE)),
          identical(is.na(x), is.na(nchar(x))))

##' nchar() for all three types :
nchars <- function(x, ...)
  vapply(c("chars", "bytes", "width"),
          function(tp) nchar(x, tp, ...), integer(length(x)))
nchars("\u200b") # in R versions (>= 2015-09-xx):
## chars bytes width
## 1 3 0
data.frame(x, nchars(x)) # all three types : same unless for NA
## force the same by forcing 'keepNA':
(ncT <- nchars(x, keepNA = TRUE)) ## .... NA NA NA ....
(ncF <- nchars(x, keepNA = FALSE))## .... 2 2 2 ....
stopifnot(apply(ncT, 1, function(.) length(unique(.))) == 1,
          apply(ncF, 1, function(.) length(unique(.))) == 1)

nlevels

The Number of Levels of a Factor

Description

Return the number of levels which its argument has.
Usage

nlevels(x)

Arguments

x an object, usually a factor.

Details

This is usually applied to a factor, but other objects can have levels.
The actual factor levels (if they exist) can be obtained with the `levels` function.

Value

The length of `levels(x)`, which is zero if x has no levels.

See Also

`levels`, `factor`.

Examples

nlevels(gl(3, 7)) # = 3

---

noquote

Class for 'no quote' Printing of Character Strings

Description

Print character strings without quotes.

Usage

noquote(obj, right = FALSE)

## S3 method for class 'noquote'
print(x, ...)

## S3 method for class 'noquote'
c(..., recursive = FALSE)

Arguments

obj any R object, typically a vector of character strings.

right optional logical eventually to be passed to print(), used by `print.default()`, indicating whether or not strings should be right aligned.

x an object of class "noquote".

... further options passed to next methods, such as `print`.

recursive for compatibility with the generic `c` function.
Details

`noquote` returns its argument as an object of class "noquote". There is a method for `c()` and subscript method ("[.noquote") which ensures that the class is not lost by subsetting. The print method (print.noquote) prints character strings without quotes ("..."). These functions exist both as utilities and as an example of using (S3) `class` and object orientation.

Examples

```r
letters
nql <- noquote(letters)
nql
nql[1:4] <- "oh"
nql[1:12]

cmp.logical <- function(log.v)
{
  ## Purpose: compact printing of logicals
  log.v <- as.logical(log.v)
  noquote(if(length(log.v) == 0)"()" else c("\.","\|")[1 + log.v])
}
cmp.logical(stats::runif(20) > 0.8)

chmat <- as.matrix(format(stackloss)) # a "typical" character matrix
## noquote(*, right=TRUE) so it prints exactly like a data frame
chmat <- noquote(chmat, right = TRUE)
chmat
```

Description

Computes a matrix norm of `x` using LAPACK. The norm can be the one ("O") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the "spectral" or "2"-norm, as determined by the value of `type`.

Usage

```r
norm(x, type = c("O", "I", "F", "M", "2"))
```
Arguments

x numeric matrix; note that packages such as Matrix define more norm() methods.

type character string, specifying the type of matrix norm to be computed. A character indicating the type of norm desired.
"0", "o" or "1" specifies the one norm, (maximum absolute column sum);
"I" or "i" specifies the infinity norm (maximum absolute row sum);
"F" or "f" specifies the Frobenius norm (the Euclidean norm of x treated as if it were a vector);
"M" or "m" specifies the maximum modulus of all the elements in x; and
"2" specifies the "spectral" or 2-norm, which is the largest singular value (svd) of x.
The default is "0". Only the first character of type[1] is used.

Details

The base method of norm() calls the Lapack function dlange.
Note that the 1-, Inf- and "M" norm is faster to calculate than the Frobenius one.
Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The matrix norm, a non-negative number.

Source

Except for norm = "2", the LAPACK routine DLANGE.
LAPACK is from http://www.netlib.org/lapack.

rcond for the (reciprocal) condition number.

Examples

(x1 <- cbind(1, 1:10))
norm(x1)
norm(x1, "I")
norm(x1, "M")
stopifnot(all.equal(norm(x1, "F"), sqrt(sum(x1^2))))

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+"))
h9 <- hilbert(9)
## all 5 types of norm:
(nTyp <- eval(formals(base::norm)$type))
sapply(nTyp, norm, x = h9)
normalizePath

Express File Paths in Canonical Form

Description

Convert file paths to canonical form for the platform, to display them in a user-understandable form and so that relative and absolute paths can be compared.

Usage

normalizePath(path, winslash = "\\", mustWork = NA)

Arguments

- **path**: character vector of file paths.
- **winslash**: the separator to be used on Windows – ignored elsewhere. Must be one of c(“/”, “\\”).
- **mustWork**: logical: if TRUE then an error is given if the result cannot be determined; if NA then a warning.

Details

Tilde-expansion (see `path.expand`) is first done on paths.

Where the Unix-alike platform supports it attempts to turn paths into absolute paths in their canonical form (no ‘./’, ‘../’ nor symbolic links). It relies on the POSIX system function `realpath`: if the platform does not have that (we know of no current example) then the result will be an absolute path but might not be canonical. Even where `realpath` is used the canonical path need not be unique, for example via hard links or multiple mounts.

On Windows it converts relative paths to absolute paths, converts short names for path elements to long names and ensures the separator is that specified by `winslash`. It will match paths case-insensitively and return the canonical case. UTF-8-encoded paths not valid in the current locale can be used.

`mustWork = FALSE` is useful for expressing paths for use in messages.

Value

A character vector.

If an input is not a real path the result is system-dependent (unless `mustWork = TRUE`, when this should be an error). It will be either the corresponding input element or a transformation of it into an absolute path.

Converting to an absolute file path can fail for a large number of reasons. The most common are

- One of more components of the file path does not exist.
- A component before the last is not a directory, or there is insufficient permission to read the directory.
- For a relative path, the current directory cannot be determined.
- A symbolic link points to a non-existent place or links form a loop.
- The canonicalized path would be exceed the maximum supported length of a file path.
Note

The canonical form of paths may not be what you expect. For example, on macOS absolute paths such as ‘/tmp’ and ‘/var’ are symbolic links.

Examples

# random tempdir
cat(normalizePath(c(R.home(), tempdir())), sep = "\n")

Description

In order to pinpoint missing functionality, the R core team uses these functions for missing R functions and not yet used arguments of existing R functions (which are typically there for compatibility purposes).

You are very welcome to contribute your code ...

Usage

.NotYetImplemented()
.NotYetUsed(arg, error = TRUE)

Arguments

arg an argument of a function that is not yet used.
error a logical. If TRUE, an error is signalled; if FALSE; only a warning is given.

See Also

the contrary, Deprecated and Defunct for outdated code.

Examples

require(graphics)
barplot(1:5, inside = TRUE) # 'inside' is not yet used
### The Number of Rows/Columns of an Array

**Description**

`nrow` and `ncol` return the number of rows or columns present in `x`. `NCOL` and `NROW` do the same treating a vector as 1-column matrix.

**Usage**

```r
nrow(x)
ncol(x)
NCOL(x)
NROW(x)
```

**Arguments**

- `x` a vector, array or data frame

**Value**

- an `integer` of length 1 or `NULL`.

**References**

**See Also**

- `dim` which returns all dimensions; `array, matrix`.

**Examples**

```r
ma <- matrix(1:12, 3, 4)
nrow(ma) # 3
ncol(ma) # 4

ncol(array(1:24, dim = 2:4)) # 3, the second dimension
NCOL(1:12) # 1
NROW(1:12) # 12
```
Double Colon and Triple Colon Operators

Description

Accessing exported and internal variables, i.e. \( R \) objects (including lazy loaded data sets) in a namespace.

Usage

\[ \text{pkg::name} \]
\[ \text{pkg:::name} \]

Arguments

- \text{pkg} \quad \text{package name: symbol or literal character string.}
- \text{name} \quad \text{variable name: symbol or literal character string.}

Details

For a package \text{pkg}, \text{pkg::name} returns the value of the exported variable \text{name} in namespace \text{pkg}, whereas \text{pkg:::name} returns the value of the internal variable \text{name}. The package namespace will be loaded if it was not loaded before the call, but the package will not be attached to the search path.

Specifying a variable or package that does not exist is an error.

Note that \text{pkg::name} does not access the objects in the environment \text{package::pkg} (which does not exist until the package’s namespace is attached): the latter may contain objects not exported from the namespace. It can access datasets made available by lazy-loading.

Note

It is typically a design mistake to use :: in your code since the corresponding object has probably been kept internal for a good reason. Consider contacting the package \text{maintainer} if you feel the need to access the object for anything but mere inspection.

See Also

\text{get} to access an object masked by another of the same name. \text{loadNamespace}, \text{asNamespace} for more about namespaces.

Examples

\begin{verbatim}
base::log
base::"+"
\end{verbatim}

## Beware -- use ': :' at your own risk! (see "Details")

\begin{verbatim}
stats:::coef.default
\end{verbatim}
ns-hooks

Hooks for Namespace Events

Description

Packages can supply functions to be called when loaded, attached, detached or unloaded.

Usage

.onLoad(libname, pkgname)
.onAttach(libname, pkgname)
.onUnload(libpath)
.onDetach(libpath)
.Last.lib(libpath)

Arguments

libname  a character string giving the library directory where the package defining the namespace was found.
pkgname  a character string giving the name of the package.
libpath  a character string giving the complete path to the package.

Details

After loading, loadNamespace looks for a hook function named .onLoad and calls it (with two unnamed arguments) before sealing the namespace and processing exports.

When the package is attached (via library or attachNamespace), the hook function .onAttach is looked for and if found is called (with two unnamed arguments) before the package environment is sealed.

If a function .onDetach is in the namespace or .Last.lib is exported from the package, it will be called (with a single argument) when the package is detached. Beware that it might be called if .onAttach has failed, so it should be written defensively. (It is called within tryCatch, so errors will not stop the package being detached.)

If a namespace is unloaded (via unloadNamespace), a hook function .onUnload is run (with a single argument) before final unloading.

Note that the code in .onLoad and .onUnload should not assume any package except the base package is on the search path. Objects in the current package will be visible (unless this is circumvented), but objects from other packages should be imported or the double colon operator should be used.

.onLoad, .onUnload, .onAttach and .onDetach are looked for as internal objects in the namespace and should not be exported (whereas .Last.lib should be).

Note that packages are not detached nor namespaces unloaded at the end of an R session unless the user arranges to do so (e.g., via .Last).

Anything needed for the functioning of the namespace should be handled at load/unload times by the .onLoad and .onUnload hooks. For example, DLLs can be loaded (unless done by a useDynLib directive in the ‘NAMESPACE’ file) and initialized in .onLoad and unloaded in .onUnload. Use .onAttach only for actions that are needed only when the package becomes visible to the user (for example a start-up message) or need to be run after the package environment has been created.
Good practice

Loading a namespace should where possible be silent, with startup messages given by `.onAttach`. These messages (and any essential ones from `.onLoad`) should use `packageStartupMessage` so they can be silenced where they would be a distraction.

There should be no calls to `library` nor `require` in these hooks. The way for a package to load other packages is via the ‘Depends’ field in the ‘DESCRIPTION’ file: this ensures that the dependence is documented and packages are loaded in the correct order. Loading a namespace should not change the search path, so rather than attach a package, dependence of a namespace on another package should be achieved by (selectively) importing from the other package’s namespace.

Uses of `library` with argument `help` to display basic information about the package should use `format` on the computed package information object and pass this to `packageStartupMessage`.

There should be no calls to `installed.packages` in startup code: it is potentially very slow and may fail in versions of R before 2.14.2 if package installation is going on in parallel. See its help page for alternatives.

Compiled code should be loaded (e.g., via `library.dynam`) in `.onLoad` or a `useDynLib` directive in the ‘NAMESPACE’ file, and not in `.onAttach`. Similarly, compiled code should not be unloaded (e.g., via `library.dynam.unload`) in `.Last.lib` nor `.onDetach`, only in `.onUnload`.

- `setHook` shows how users can set hooks on the same events, and lists the sequence of events involving all of the hooks.
- `reg.finalizer` for hooks to be run at the end of a session.
- `loadNamespace` for more about namespaces.

---

ns-load  

Loading and Unloading Name Spaces

Description

Functions to load and unload name spaces.

Usage

- `attachNamespace(ns, pos = 2L, depends = NULL)`
- `loadNamespace(package, lib.loc = NULL,` 
  `  keep.source = getOption("keep.source.pkgs"),` 
  `  partial = FALSE, versionCheck = NULL)`
- `requireNamespace(package, ..., quietly = FALSE)`
- `loadedNamespaces()`
- `unloadNamespace()`
- `isNamespaceLoaded(name)`

Arguments

- `ns` string or name space object.
- `pos` integer specifying position to attach.
- `depends` NULL or a character vector of dependencies to be recorded in object .Depends in the package.
package string naming the package/name space to load.
lib.loc character vector specifying library search path.
keep.source Now ignored except during package installation. For more details see this argument to library.
partial logical; if true, stop just after loading code.
versionCheck NULL or a version specification (a list with components op and version)).
quietly logical: should progress and error messages be suppressed?
name string or 'name', see as.symbol, of a package, e.g., "stats".
... further arguments to be passed to loadNamespace.

Details
The functions loadNamespace and attachNamespace are usually called implicitly when library is used to load a name space and any imports needed. However it may be useful at times to call these functions directly.

loadNamespace loads the specified name space and registers it in an internal data base. A request to load a name space when one of that name is already loaded has no effect. The arguments have the same meaning as the corresponding arguments to library, whose help page explains the details of how a particular installed package comes to be chosen. After loading, loadNamespace looks for a hook function named .onLoad as an internal variable in the name space (it should not be exported). Partial loading is used to support installation with lazy-loading.
Optionally the package licence is checked during loading: see section ‘Licenses’ in the help for library.

loadNamespace does not attach the name space it loads to the search path. attachNamespace can be used to attach a frame containing the exported values of a name space to the search path (but this is almost always done via library). The hook function .onAttach is run after the name space exports are attached.

requireNamespace is a wrapper for loadNamespace analogous to require that returns a logical value.

loadedNamespaces returns a character vector of the names of the loaded name spaces.
isNamespaceLoaded(pkg) is equivalent to but more efficient than pkg %in% loadedNamespaces().

unloadNamespace can be used to attempt to force a name space to be unloaded. If the name space is attached, it is first detached, thereby running a .onDetach or .Last.lib function in the name space if one is exported. An error is signaled and the name space is not unloaded if the name space is imported by other loaded name spaces. If defined, a hook function .onUnload is run before removing the name space from the internal registry.

See the comments in the help for detach about some issues with unloading and reloading name spaces.

Value
attachNamespace returns invisibly the package environment it adds to the search path.
loadNamespace returns the name space environment, either one already loaded or the one the function causes to be loaded.
requireNamespace returns TRUE if it succeeds or FALSE.
loadedNamespaces returns a character vector.
unloadNamespace returns NULL, invisibly.

getNamespace, asNamespace, topenv, .onLoad (etc); further environment.

Examples
(lns <- loadedNamespaces())
statL <- isNamespaceLoaded("stats")
stopifnot( identical(statL, "stats" %in% lns) )

## The string "foo" and the symbol 'foo' can be used interchangably here:
stopifnot( identical(isNamespaceLoaded("foo" ), FALSE),
           identical(isNamespaceLoaded(quote(foo)), FALSE),
           identical(isNamespaceLoaded(quote(stats)), statL))

hasS <- isNamespaceLoaded("splines") # (to restore if needed)
Sns <- asNamespace("splines") # loads it if not already
stopifnot( isNamespaceLoaded("splines"))
unloadNamespace(Sns) # unloading the NS 'object'
stopifnot( ! isNamespaceLoaded("splines"))
if (hasS) loadNamespace("splines") # (restoring previous state)

ns-topenv

Top Level Environment

Description
Finding the top level environment from an environment envir and its enclosing environments.

Usage
topenv(envir = parent.frame(),
       matchThisEnv = getOption("topLevelEnvironment"))

Arguments
envir
  environment.
matchThisEnv
  return this environment, if it matches before any other criterion is satisfied. The
default, the option ‘topLevelEnvironment’, is set by sys.source, which treats
a specific environment as the top level environment. Supplying the argument as
NULL means it will never match.

Details
topenv returns the first top level environment found when searching envir and its enclosing envi-
ronments. An environment is considered top level if it is the internal environment of a namespace,
a package environment in the search path, or .GlobalEnv.
### NULL

**See Also**

`environment`, notably `parent.env()` on “enclosing environments”; `loadNamespace` for more on namespaces.

**Examples**

```r
topenv(.GlobalEnv)
topenv(new.env()) # also global env
topenv(environment(ls))# namespace:base
topenv(environment(lm))# namespace:stats
```

---

**NULL**  
*The Null Object*

**Description**

`NULL` represents the null object in R: it is a reserved word. `NULL` is often returned by expressions and functions whose value is undefined.

**Usage**

```r
NULL
as.null(x, ...)
is.null(x)
```

**Arguments**

- **x** an object to be tested or coerced.
- **...** ignored.

**Details**

`NULL` can be indexed (see `Extract`) in just about any syntactically legal way: whether it makes sense or not, the result is always `NULL`. Objects with value `NULL` can be changed by replacement operators and will be coerced to the type of the right-hand side.

`NULL` is also used as the empty `pairlist`: see the examples. Because pairlists are often promoted to lists, you may encounter `NULL` being promoted to an empty list.

Objects with value `NULL` cannot have attributes as there is only one null object: attempts to assign them are either an error (`attr`) or promote the object to an empty list with attribute(s) (`attributes` and `structure`).

**Value**

`as.null` ignores its argument and returns `NULL`.

`is.null` returns `TRUE` if its argument’s value is `NULL` and `FALSE` otherwise.

**Note**

`is.null` is a primitive function.
numeric

References

Examples

```r
is.null(list())  # FALSE (on purpose!)
is.null(pairlist()) # TRUE
is.null(integer(0)) # FALSE
is.null(logical(0)) # FALSE
as.null(list(a = 1, b = "c"))
```

Numeric Vectors

Description

Creates or coerces objects of type "numeric". `is.numeric` is a more general test of an object being interpretable as numbers.

Usage

```r
numeric(length = 0)
as.numeric(x, ...)
is.numeric(x)
```

Arguments

- `length` A non-negative integer specifying the desired length. Double values will be coerced to integer: supplying an argument of length other than one is an error.
- `x` object to be coerced or tested.
- `...` further arguments passed to or from other methods.

Details

`numeric` is identical to `double` (and `real`). It creates a double-precision vector of the specified length with each element equal to 0.

`as.numeric` is a generic function, but S3 methods must be written for `as.double`. It is identical to `as.double`.

`is.numeric` is an internal generic primitive function: you can write methods to handle specific classes of objects, see `InternalMethods`. It is not the same as `is.double`. Factors are handled by the default method, and there are methods for classes "Date", "POSIXt" and "difftime" (all of which return false). Methods for `is.numeric` should only return true if the base type of the class is `double` or `integer` and values can reasonably be regarded as numeric (e.g., arithmetic on them makes sense, and comparison should be done via the base type).

Value

for `numeric` and `as.numeric` see `double`.

The default method for `is.numeric` returns TRUE if its argument is of `mode` "numeric" (type "double" or type "integer") and not a factor, and FALSE otherwise. That is, `is.integer(x) || is.double(x), or (mode(x) == "numeric") && !is.factor(x).`
Warning

If x is a factor, as.numeric will return the underlying numeric (integer) representation, which is often meaningless as it may not correspond to the factor levels, see the ‘Warning’ section in factor (and the 2nd example below).

S4 methods

as.numeric and is.numeric are internally S4 generic and so methods can be set for them via setMethod.

To ensure that as.numeric and as.double remain identical, S4 methods can only be set for as.numeric.

Note on names

It is a historical anomaly that R has two names for its floating-point vectors, double and numeric (and formerly had real).

double is the name of the type, numeric is the name of the mode and also of the implicit class. As an S4 formal class, use "numeric".

The potential confusion is that R has used mode "numeric" to mean ‘double or integer’, which conflicts with the S4 usage. Thus is.numeric tests the mode, not the class, but as.numeric (which is identical to as.double) coerces to the class.

References

See Also
double, integer, storage.mode.

Examples

as.numeric(c("-1"," 2.7 ","B")) # (-0.1, 2.7, NA) + warning

as.numeric(factor(5:10)) # not what you’d expect
f <- factor(1:5)
## what you typically meant and want:
as.numeric(as.character(f))
## the same, considerably (for long factors) more efficient:
as.numeric(levels(f))[f]
Details

R parses numeric constants in its input in a very similar way to C99 floating-point constants. Inf and NaN are numeric constants (with typeof(.) "double"). In text input (e.g., in scan and as.double), these are recognized ignoring case as is infinity as an alternative to Inf. NA_real_ and NA_integer_ are constants of types "double" and "integer" representing missing values. All other numeric constants start with a digit or period and are either a decimal or hexadecimal constant optionally followed by L.

Hexadecimal constants start with 0x or 0X followed by a nonempty sequence from 0-9 a-f A-F . which is interpreted as a hexadecimal number, optionally followed by a binary exponent. A binary exponent consists of a P or p followed by an optional plus or minus sign followed by a non-empty sequence of (decimal) digits, and indicates multiplication by a power of two. Thus 0x123p456 is 291 \times 2^{456}.

Decimal constants consist of a nonempty sequence of digits possibly containing a period (the decimal point), optionally followed by a decimal exponent. A decimal exponent consists of an E or e followed by an optional plus or minus sign followed by a non-empty sequence of digits, and indicates multiplication by a power of ten.

Values which are too large or too small to be representable will overflow to Inf or underflow to 0.0.

A numeric constant immediately followed by i is regarded as an imaginary complex number.

An numeric constant immediately followed by L is regarded as an integer number when possible (and with a warning if it contains a ".").

Only the ASCII digits 0–9 are recognized as digits, even in languages which have other representations of digits. The ‘decimal separator’ is always a period and never a comma.

Note that a leading plus or minus is not regarded by the parser as part of a numeric constant but as a unary operator applied to the constant.

Note

When a string is parsed to input a numeric constant, the number may or may not be representable exactly in the C double type used. If not one of the nearest representable numbers will be returned.

R’s own C code is used to convert constants to binary numbers, so the effect can be expected to be the same on all platforms implementing full IEC 600559 arithmetic (the most likely area of difference being the handling of numbers less than .Machine$double.xmin). The same code is used by scan.

See Also

Syntax. For complex numbers, see complex. Quotes for the parsing of character constants, Reserved for the “reserved words” in R.

Examples

```r
## You can create numbers using fixed or scientific formatting.
2.1
2.1e10
-2.1E-10
```

```r
## The resulting objects have class numeric and type double.
class(2.1)
typeof(2.1)
```
## This holds even if what you typed looked like an integer.
class(2)
typeof(2)

## If you actually wanted integers, use an "L" suffix.
class(2L)
typeof(2L)

## These are equal but not identical
2 == 2L
identical(2, 2L)

## You can write numbers between 0 and 1 without a leading "0"
## (but typically this makes code harder to read)
.1234

sqrt(1i) # remember elementary math?
utils::str(0xA0)
identical(1L, as.integer(1))

## You can combine the "0x" prefix with the "L" suffix :
identical(0xFL, as.integer(15))

### numeric_version  Numeric Versions

#### Description
A simple S3 class for representing numeric versions including package versions, and associated methods.

#### Usage
numeric_version(x, strict = TRUE)
package_version(x, strict = TRUE)
R_system_version(x, strict = TRUE)
getRversion()

#### Arguments
- **x**
  a character vector with suitable numeric version strings (see ‘Details’); for package_version, alternatively an R version object as obtained by R.version.
- **strict**
  a logical indicating whether invalid numeric versions should result in an error (default) or not.

#### Details
Numeric versions are sequences of one or more non-negative integers, usually (e.g., in package ‘DESCRIPTION’ files) represented as character strings with the elements of the sequence concatenated and separated by single ‘.’ or ‘-’ characters. R package versions consist of at least two such integers, an R system version of exactly three (major, minor and patchlevel).
Functions `numeric_version`, `package_version` and `R_system_version` create a representation from such strings (if suitable) which allows for coercion and testing, combination, comparison, summaries (min/max), inclusion in data frames, subscripting, and printing. The classes can hold a vector of such representations.

`getRversion` returns the version of the running R as an R system version object.

The `[ ]` operator extracts or replaces a single version. To access the integers of a version use two indices: see the examples.

**See Also**

`compareVersion`, `packageVersion` for the version of a specific R package. `R.version` etc for the version of R (and the information underlying `getRversion()`).

**Examples**

```r
x <- package_version(c("1.2-4", "1.2-3", "2.1"))
x < "1.4-2.3"
c(min(x), max(x))
x[2, 2]
x$major
x$minor

if(getRversion() <= "2.5.0") {
  # work around missing feature
  cat("Your version of R, ", as.character(getRversion()),
    ", is outdated.\n",
    "Now trying to work around that ...\n", sep = "")
}

x[[c(1, 3)]] # '4' as a numeric vector, same as x[1, 3]
x[1, 3] # 4 as an integer
x[[2, 3]] <- 0 # zero the patchlevel
x[[c(2, 3)]] <- 0 # same
x[[3]] <- "2.2.3"; x
x <- c(x, package_version("0.0"))
is.na(x)[4] <- TRUE
stopifnot(identical(is.na(x), c(rep(FALSE,3), TRUE)),
          anyNA(x))
```

---

**octmode**

**Display Numbers in Octal**

**Description**

Convert or print integers in octal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

**Usage**

```r
as.octmode(x)
```

## S3 method for class 'octmode'

```r
as.character(x, ...)
```
## S3 method for class 'octmode'
format(x, width = NULL, ...)

## S3 method for class 'octmode'
print(x, ...)

### Arguments

- **x**: An object, for the methods inheriting from class "octmode".
- **width**: NULL or a positive integer specifying the minimum field width to be used, with padding by leading zeroes.
- **...**: further arguments passed to or from other methods.

### Details

Class "octmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in octal notation, specifically for Unix-like file permissions such as 755. Subsetting ([) works too.

If width = NULL (the default), the output is padded with leading zeroes to the smallest width needed for all the non-missing elements.

as.octmode can convert integers (of type "integer" or "double") and character vectors whose elements contain only digits 0-7 (or are NA) to class "octmode".

There is a ! method and |, & and xor methods: these recycle their arguments to the length of the longer and then apply the operators bitwise to each element.

### See Also

These are auxiliary functions for file.info.

hexmode, sprintf for other options in converting integers to octal, strtoi to convert octal strings to integers.

### Examples

```r
(on <- as.octmode(c(16, 32, 127:129))) # "020" "040" "177" "200" "201"
unclass(on[3:4]) # subsetting

## manipulate file modes
fmode <- as.octmode("170")
(fmode | "644") & "755"

umask <- Sys.umask(NA) # depends on platform
c(fmode, "666", "755") & !umask
```
on.exit

Function Exit Code

Description

on.exit records the expression given as its argument as needing to be executed when the current function exits (either naturally or as the result of an error). This is useful for resetting graphical parameters or performing other cleanup actions.

If no expression is provided, i.e., the call is on.exit(), then the current on.exit code is removed.

Usage

on.exit(expr = NULL, add = FALSE, after = TRUE)

Arguments

expr an expression to be executed.

add if TRUE, add expr to be executed after any previously set expressions (or before if after is FALSE); otherwise (the default) expr will overwrite any previously set expressions.

after if add is TRUE and after is FALSE, then expr will be added on top of the expressions that were already registered. The resulting last in first out order is useful for freeing or closing resources in reverse order.

Details

The expr argument passed to on.exit is recorded without evaluation. If it is not subsequently removed/replaced by another on.exit call in the same function, it is evaluated in the evaluation frame of the function when it exits (including during standard error handling). Thus any functions or variables in the expression will be looked for in the function and its environment at the time of exit: to capture the current value in expr use substitute or similar.

If multiple on.exit expressions are set using add = TRUE then all expressions will be run even if one signals an error.

This is a ‘special’ primitive function: it only evaluates the argument add.

Value

Invisible NULL.

References

See Also

sys.on.exit which returns the expression stored for use by on.exit() in the function in which sys.on.exit() is evaluated.
Examples

require(graphics)

opar <- par(mai = c(1,1,1,1))
on.exit(par(opar))
options

Options Settings

Description

Allow the user to set and examine a variety of global options which affect the way in which R computes and displays its results.

Usage

options(...)

getOption(x, default = NULL)

Arguments

... any options can be defined, using name = value. However, only the ones below are used in base R.

Options can also be passed by giving a single unnamed argument which is a named list.

x a character string holding an option name.

default if the specified option is not set in the options list, this value is returned. This facilitates retrieving an option and checking whether it is set and setting it separately if not.

Details

Invoking options() with no arguments returns a list with the current values of the options. Note that not all options listed below are set initially. To access the value of a single option, one should use, e.g., getOption("width") rather than options("width") which is a list of length one.

Value

For getOption, the current value set for option x, or NULL if the option is unset.

For options(), a list of all set options sorted by name. For options(name), a list of length one containing the set value, or NULL if it is unset. For uses setting one or more options, a list with the previous values of the options changed (returned invisibly).

Options used in base R

add.smooth: typically logical, defaulting to TRUE. Could also be set to an integer for specifying how many (simulated) smooths should be added. This is currently only used by plot.lm.

askYesNo: a function (typically set by a front-end) to ask the user binary response functions in a consistent way, or a vector of strings used by askYesNo to use as default responses for such questions.

browserNLdisabled: logical: whether newline is disabled as a synonym for "n" in the browser.

checkPackageLicense: logical, not set by default. If true, loadNamespace asks a user to accept any non-standard license at first load of the package.
options

check.bounds: logical, defaulting to FALSE. If true, a warning is produced whenever a vector (atomic or list) is extended, by something like `x <- 1:3; x[5] <- 6`.

CBoundsCheck: logical, controlling whether `.C` and `.Fortran` make copies to check for array overruns on the atomic vector arguments.

Initially set from value of the environment variable `R_C_BOUNDS_CHECK` (set to yes to enable).

continue: a non-empty string setting the prompt used for lines which continue over one line.

defaultPackages: the packages that are attached by default when R starts up. Initially set from value of the environment variable `R_DEFAULT_PACKAGES`, or if that is unset to `c("datasets", "utils", "grDevices", "graphics", "stats", "methods")`. (Set `R_DEFAULT_PACKAGES` to `NULL` or a comma-separated list of package names.) It will not work to set this in a `.Rprofile` file, as its value is consulted before that file is read.

deparse.cutoff: integer value controlling the printing of language constructs which are deparsed. Default 60.

deparse.max.lines: controls the number of lines used when deparsing in traceback, browser, and upon entry to a function whose debugging flag is set. Initially unset, and only used if set to a positive integer.

digits: controls the number of significant digits to print when printing numeric values. It is a suggestion only. Valid values are 1...22 with default 7. See the note in `print.default` about values greater than 15.

digitssecs: controls the maximum number of digits to print when formatting time values in seconds. Valid values are 0..6 with default 0. See `strftime`.

download.file.extra: Extra command-line argument(s) for non-default methods: see `download.file`.

download.file.method: Method to be used for download.file. Currently download methods "internal", "wininet" (Windows only), "libcurl", "wget" and "curl" are available. If not set, `method = "auto"` is chosen: see `download.file`.

echo: logical. Only used in non-interactive mode, when it controls whether input is echoed.

Command-line option `--slave` sets this to `FALSE`, but otherwise it starts the session as `TRUE`.

encoding: The name of an encoding, default "native.enc". See `connections`.

error: either a function or an expression governing the handling of non-catastrophic errors such as those generated by `stop` as well as by signals and internally detected errors. If the option is a function, a call to that function, with no arguments, is generated as the expression. The default value is `NULL`: see `stop` for the behaviour in that case. The functions `dump.frames` and `recover` provide alternatives that allow post-mortem debugging. Note that these need to be specified as e.g. `options(error = utils::recover)` in startup files such as `.Rprofile`.

expressions: sets a limit on the number of nested expressions that will be evaluated. Valid values are 25...50000 with default 5000. If you increase it, you may also want to start R with a larger protection stack; see `--max-ppsize` in `Memory`. Note too that you may cause a segfault from overflow of the C stack, and on OSes where it is possible you may want to increase that. Once the limit is reached an error is thrown. The current number under evaluation can be found by calling `Cstack_info`.

interrupt: a function taking no arguments to be called on a user interrupt if the interrupt condition is not otherwise handled.

keep.source: When `TRUE`, the source code for functions (newly defined or loaded) is stored internally allowing comments to be kept in the right places. Retrieve the source by printing or using `deparse(fn, control = "useSource")`.

The default is `interactive()`, i.e., `TRUE` for interactive use.
options

keep.source.pkgs: As for keep.source, used only when packages are installed. Defaults to FALSE unless the environment variable R_KEEP_PKG_SOURCE is set to yes.

matprod: a string selecting the implementation of the matrix products %*%, crossprod, and tcrossprod for double and complex vectors:

"internal" uses an unoptimized 3-loop algorithm which correctly propagates NaN and Inf values and is consistent in precision with other summation algorithms inside R like sum or colSums (which now means that it uses a long double accumulator for summation if available and enabled, see capabilities).

"default" uses BLAS to speed up computation, but to ensure correct propagation of NaN and Inf values it uses an unoptimized 3-loop algorithm for inputs that may contain NaN or Inf values. When deemed beneficial for performance, "default" may call the 3-loop algorithm unconditionally, i.e., without checking the input for NaN/Inf values. The 3-loop algorithm uses (only) a double accumulator for summation, which is consistent with the reference BLAS implementation.

"blas" uses BLAS unconditionally without any checks and should be used with extreme caution. BLAS libraries do not propagate NaN or Inf values correctly and for inputs with NaN/Inf values the results may be undefined.

"default.simd" is experimental and will likely be removed in future versions of R. It provides the same behavior as "default", but the check whether the input contains NaN/Inf values is faster on some SIMD hardware. On older systems it will run correctly, but may be much slower than "default".

max.print: integer, defaulting to 99999. print or show methods can make use of this option, to limit the amount of information that is printed, to something in the order of (and typically slightly less than) max.print entries.

OutDec: character string containing a single character. The preferred character to be used as the decimal point in output conversions, that is in printing, plotting, format and as.character but not when deparsing nor by sprintf nor formatC (which are sometimes used prior to printing.)

crossprod, and tcrossprod for double and complex vectors:

max.print: integer, defaulting to 99999. print or show methods can make use of this option, to limit the amount of information that is printed, to something in the order of (and typically slightly less than) max.print entries.

OutDec: character string containing a single character. The preferred character to be used as the decimal point in output conversions, that is in printing, plotting, format and as.character but not when deparsing nor by sprintf nor formatC (which are sometimes used prior to printing.)

pager: the command used for displaying text files by file.show. Defaults to 'R_HOME/bin/pager', which is a shell script running the command-line specified by the environment variable PAGER whose default is set at configuration, usually to less. Can be a character string or an R function, in which case it needs to accept the arguments (files, header,title, delete.file) corresponding to the first four arguments of file.show.

crossprod, and tcrossprod for double and complex vectors:

max.print: integer, defaulting to 99999. print or show methods can make use of this option, to limit the amount of information that is printed, to something in the order of (and typically slightly less than) max.print entries.

OutDec: character string containing a single character. The preferred character to be used as the decimal point in output conversions, that is in printing, plotting, format and as.character but not when deparsing nor by sprintf nor formatC (which are sometimes used prior to printing.)

pager: the command used for displaying text files by file.show. Defaults to 'R_HOME/bin/pager', which is a shell script running the command-line specified by the environment variable PAGER whose default is set at configuration, usually to less. Can be a character string or an R function, in which case it needs to accept the arguments (files, header,title, delete.file) corresponding to the first four arguments of file.show.

papersize: the default paper format used by postscript; set by environment variable R_PAPERSIZE when R is started: if that is unset or invalid it defaults to a value derived from the locale category LC_PAPER, or if that is unavailable to a default set when R was built.

PCRE_limit_recursion: Logical: should grep(perl = TRUE) and similar limit the maximal recursion allowed when matching? PCRE can be built not to use a recursion stack (see pcre_config, but it is by default with a recursion limit of 10000000 which potentially needs a very large C stack: see the discussion at http://www.pcre.org/original/doc/html/pcrestack.html. If true, the limit is reduced using R's estimate of the C stack size available (if known), otherwise 10000. If NA, the limit is imposed only if any input string has 1000 or more bytes.

PCRE_study: Logical or integer: should grep(perl = TRUE) and similar 'study' the patterns? Either logical or a numerical threshold for the minimum number of strings to be matched for the pattern to be studied (the default is 10)). Missing values and negative numbers are treated as false.

PCRE_use_JIT: Logical: should grep(perl = TRUE), strsplit(perl = TRUE) and similar make use of PCRE's Just-In-Time compiler for studied patterns, if available? Missing values are treated as false.
pdfviewer: default PDF viewer. The default is set from the environment variable R_PDFVIEWER, the default value of which is set when R is configured.

printcmd: the command used by postscript for printing; set by environment variable R_PRINTCMD when R is started. This should be a command that expects either input to be piped to 'stdin' or to be given a single filename argument. Usually set to "lpr" on a Unix-alike.

prompt: a non-empty string to be used for R's prompt; should usually end in a blank (" ").

rl_word_breaks: Used for the readline-based terminal interface. Default value " \n\n\\\n\n\\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\\n\n
signalled. An object called `last.warning` is created and can be printed through the function `warnings`. If `warn` is one, warnings are printed as they occur. If `warn` is two or larger all warnings are turned into errors.

- `warnPartialMatchArgs`: logical. If true, warns if partial matching is used in argument matching.
- `warnPartialMatchAttr`: logical. If true, warns if partial matching is used in extracting attributes via `attr`.
- `warnPartialMatchDollar`: logical. If true, warns if partial matching is used for extraction by `$`.
- `warning.expression`: an R code expression to be called if a warning is generated, replacing the standard message. If non-null it is called irrespective of the value of option `warn`.
- `warning.length`: sets the truncation limit for error and warning messages. A non-negative integer, with allowed values 100...8170, default 1000.
- `nwarnings`: the limit for the number of warnings kept when `warn = 0`, default 50. This will discard messages if called whilst they are being collected. If you increase this limit, be aware that the current implementation pre-allocates the equivalent of a named list for them, i.e., do not increase it to more than say a million.
- `width`: controls the maximum number of columns on a line used in printing vectors, matrices and arrays, and when filling by `cat`.

Columns are normally the same as characters except in East Asian languages.

You may want to change this if you re-size the window that R is running in. Valid values are 10...10000 with default normally 80. (The limits on valid values are in file `Print.h` and can be changed by re-compiling R.) Some R consoles automatically change the value when they are resized.

See the examples on `Startup` for one way to set this automatically from the terminal width when R is started.

The ‘factory-fresh’ default settings of some of these options are

```
add.smooth          TRUE
check.bounds        FALSE
continue            "+ "
digits              7
echo                TRUE
encoding            "native.enc"
error               NULL
expressions         5000
keep.source         interactive()
keep.source.pkgs    FALSE
max.print            999999
OutDec              "."  
prompt              "> "
scipen              0
show.error.messages  TRUE
timeout             60
verbose             FALSE
warn                0
warning.length      1000
width               80
```

Others are set from environment variables or are platform-dependent.
**Options set in package grDevices**

These will be set when package `grDevices` (or its namespace) is loaded if not already set.

- **bitmapType**: (Unix-only) character. The default type for the bitmap devices such as `png`. Defaults to "cairo" on systems where that is available, or to "quartz" on macOS where that is available.

- **device**: a character string giving the name of a function, or the function object itself, which when called creates a new graphics device of the default type for that session. The value of this option defaults to the normal screen device (e.g., `X11`, `windows` or `quartz`) for an interactive session, and `pdf` in batch use or if a screen is not available. If set to the name of a device, the device is looked for first from the global environment (that is down the usual search path) and then in the `grDevices` namespace. The default values in interactive and non-interactive sessions are configurable via environment variables `R_INTERACTIVE_DEVICE` and `R_DEFAULT_DEVICE` respectively.

- **device.ask.default**: logical. The default for `devAskNewPage("ask")` when a device is opened.

- **locatorBell**: logical. Should selection in `locator` and `identify` be confirmed by a bell? Default `TRUE`. Honoured at least on `X11` and windows devices.

**Other options used by package graphics**

- **max.contour.segments**: positive integer, defaulting to 25000 if not set. A limit on the number of segments in a single contour line in `contour` or `contourLines`.

**Options set in package stats**

These will be set when package `stats` (or its namespace) is loaded if not already set.

- **contrasts**: the default `contrasts` used in model fitting such as with `aov` or `lm`. A character vector of length two, the first giving the function to be used with unordered factors and the second the function to be used with ordered factors. By default the elements are named `c("unordered", "ordered")`, but the names are unused.

- **na.action**: the name of a function for treating missing values (`NA`’s) for certain situations, see `na.action` and `na.pass`.

- **show.coef.Pvalues**: logical, affecting whether P values are printed in summary tables of coefficients. See `printCoefmat`.

- **show.nls.convergence**: logical, should `nls` convergence messages be printed for successful fits?

- **show.signif.stars**: logical, should stars be printed on summary tables of coefficients? See `printCoefmat`.

- **ts.eps**: the relative tolerance for certain time series (`ts`) computations. Default `1e-05`.

- **ts.S.compat**: logical. Used to select S compatibility for plotting time-series spectra. See the description of argument `log` in `plot.spec`.

**Options set in package utils**

These will be set when package `utils` (or its namespace) is loaded if not already set.

browser: The HTML browser to be used by `browseURL`. This sets the default browser on UNIX or a non-default browser on Windows. Alternatively, an R function that is called with a URL as its argument. See `browseURL` for further details.

caddress: default Cc: address used by `create.post` (and hence `bug.report` and `help.request`). Can be `FALSE` or “”.

citation.bibtex.max: default 1; the maximal number of bibentries (bibentry) in a citation for which the bibtex version is printed in addition to the text one.

de.cellwidth: integer: the cell widths (number of characters) to be used in the data editor `dataentry`. If this is unset (the default), 0, negative or NA, variable cell widths are used.

demo.ask: default for the `ask` argument of `demo`.

editor: a non-empty string or a function that sets the default text editor, e.g., for `edit`. Set from the environment variable `EDITOR` on UNIX, or if unset `VISUAL` or `vi`.

e.example.ports: default for the `ask` argument of `example`.

help.ports: optional integer vector for setting ports of the internal HTTP server, see `startDynamicHelp`.

help.search.types: default types of documentation to be searched by `help.search` and `??`.

help.try.all.packages: default for an argument of `help`.

help_type: default for an argument of `help`, used also as the help type by `?`.

HTTPUserAgent: string used as the user agent in HTTP(S) requests. If `NULL`, requests will be made without a user agent header. The default is R `<version> <platform> <arch> <os>`.

install.lock: logical: should per-directory package locking be used by `install.packages`? Most useful for binary installs on macOS and Windows, but can be used in a startup file for source installs via `R CMD INSTALL`. For binary installs, can also be the character string “pkglock”.

internet.info: The minimum level of information to be printed on URL downloads etc, using the “internal” and “libcurl” methods. Default is 2, for failure causes. Set to 1 or 0 to get more detailed information (for the “internal” method 0 provides more information than 1).

install.packages.check.source: Used by `install.packages` (and indirectly `update.packages`) on platforms which support binary packages. Possible values “yes” and “no”, with unset being equivalent to “yes”.

install.packages.compile.from.source: Used by `install.packages(type = "both")` (and indirectly `update.packages`) on platforms which support binary packages. Possible values are “never”, “interactive” (which means ask in interactive use and “never” in batch use) and “always”. The default is taken from environment variable R_COMPILE_AND_INSTALL_PACKAGES, with default “interactive” if unset. However, `install.packages` uses “never” unless a make program is found, consulting the environment variable MAKE.

mailer: default emailing method used by `create.post` and hence `bug.report` and `help.request`.

menu.graphics: Logical: should graphical menus be used if available?. Defaults to TRUE. Currently applies to `select.list`, `chooseCRANmirror`, `setRepositories` and to select from multiple (text) help files in `help`.
pkgType: The default type of packages to be downloaded and installed – see `install.packages`. Possible values are "source" (the default except under a CRAN macOS build), "mac.binary.el-capitan" and "both" (the default for CRAN macOS builds). Windows uses "win.binary". ("mac.binary.mavericks", "mac.binary.leopard", "mac.binary.universal" are no longer in use.) Value "binary" is a synonym for the native binary type (if there is one); "both" is used by `install.packages` to choose between source and binary installs.

repos: URLs of the repositories for use by `update.packages`. Defaults to `c(CRAN="@CRAN@")`, a value that causes some utilities to prompt for a CRAN mirror. To avoid this do set the CRAN mirror, by something like `local({r <- getOption("repos"); r["CRAN"] <- "http://my.local.cran"; options(repos = r))}). Note that you can add more repositories (Bioconductor, R-Forge, Rforge.net ...) using `setRepositories`.

SweaveHooks, SweaveSyntax: see `Sweave`.

unzip: a character string used by `unzip`: the path of the external program `unzip` or "internal". Defaults to the value of `R_UNZIPCMD`, which is set in `etc/Renviron` if an `unzip` command was found during configuration.

Options set in package `parallel`

These will be set when package `parallel` (or its namespace) is loaded if not already set.

mc.cores: a integer giving the maximum allowed number of additional R processes allowed to be run in parallel to the current R process. Defaults to the setting of the environment variable `MC_CORES` if set. Most applications which use this assume a limit of 2 if it is unset.

Options used on Unix only

dvipscmd: character string giving a command to be used in the (deprecated) off-line printing of help pages via PostScript. Defaults to "dvips".

Options used on Windows only

warn.FPU: logical, by default undefined. If true, a warning is produced whenever `dyn.load` repairs the control word damaged by a buggy DLL.

Note

For compatibility with S there is a visible object `.Options` whose value is a pairlist containing the current `options()` (in no particular order). Assigning to it will make a local copy and not change the original.

## End(Not run)

---

order Ordering Permutation
Description

order returns a permutation which rearranges its first argument into ascending or descending order, breaking ties by further arguments. sort.list is the same, using only one argument. See the examples for how to use these functions to sort data frames, etc.

Usage

order(..., na.last = TRUE, decreasing = FALSE, method = c("auto", "shell", "radix"))
sort.list(x, partial = NULL, na.last = TRUE, decreasing = FALSE, method = c("auto", "shell", "quick", "radix"))

Arguments

... a sequence of numeric, complex, character or logical vectors, all of the same length, or a classed R object.
x an atomic vector.
partial vector of indices for partial sorting. (Non-NULL values are not implemented.)
decreasing logical. Should the sort order be increasing or decreasing? For the "radix" method, this can be a vector of length equal to the number of arguments in .... For the other methods, it must be length one.
na.last for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed (see 'Note'.)
method the method to be used: partial matches are allowed. The default ("auto") implies "radix" for short numeric vectors, integer vectors, logical vectors and factors. Otherwise, it implies "shell". For details of methods "shell", "quick", and "radix", see the help for sort.

Details

In the case of ties in the first vector, values in the second are used to break the ties. If the values are still tied, values in the later arguments are used to break the tie (see the first example). The sort used is stable (except for method = "quick"), so any unresolved ties will be left in their original ordering.

Complex values are sorted first by the real part, then by the imaginary part. Except for method "radix", the sort order for character vectors will depend on the collating sequence of the locale in use: see Comparison.

The "shell" method is generally the safest bet and is the default method, except for short factors, numeric vectors, integer vectors and logical vectors, where "radix" is assumed. Method "radix" stably sorts logical, numeric and character vectors in linear time. It outperforms the other methods, although there are caveats (see sort). Method "quick" for sort.list is only supported for numeric x with na.last = NA, is not stable, and is slower than "radix".

partial = NULL is supported for compatibility with other implementations of S, but no other values are accepted and ordering is always complete.

For a classed R object, the sort order is taken from xtfm: as its help page notes, this can be slow unless a suitable method has been defined or is.numeric(x) is true. For factors, this sorts on the internal codes, which is particularly appropriate for ordered factors.
An integer vector unless any of the inputs has $2^{31}$ or more elements, when it is a double vector.

Warning

In programmatic use it is unsafe to name the ... arguments, as the names could match current or future control arguments such as decreasing. A sometimes-encountered unsafe practice is to call `do.call('order', df_obj)` where `df_obj` might be a data frame: copy `df_obj` and remove any names, for example using `unname`.

Note

`sort.list` can get called by mistake as a method for `sort` with a list argument: it gives a suitable error message for list `x`.

There is a historical difference in behaviour for `na.last = NA`: `sort.list` removes the NAs and then computes the order amongst the remaining elements: `order` computes the order amongst the non-NA elements of the original vector. Thus

```r
x[order(x, na.last = NA)]
zz <- x[!is.na(x)]; zz[sort.list(x, na.last = NA)]
```

both sort the non-NA values of `x`.

Prior to R 3.3.0 method = "radix" was only supported for integers of range less than 100,000.

References

See Also

`sort`, `rank`, `xtfrm`.

Examples

```r
require(stats)

(ii <- order(x <- c(1,1,3:1,1:4,3), y <- c(9,9:1), z <- c(2,1:9)))
## 6 5 2 1 7 4 10 8 3 9
rbind(x, y, z)[,ii] # shows the reordering (ties via 2nd & 3rd arg)

## Suppose we wanted descending order on y.
## A simple solution for numeric 'y' is
rbind(x, y, z)[, order(x, -y, z)]
## More generally we can make use of `xtfrm`
cy <- as.character(y)
rbind(x, y, z)[, order(x, -xtfrm(cy), z)]
## The radix sort supports multiple 'decreasing' values:
rbind(x, y, z)[, order(x, cy, z, decreasing = c(FALSE, TRUE, FALSE),
               method="radix")]
```

## Sorting data frames:
dd <- transform(data.frame(x, y, z),
    z = factor(z, labels = LETTERS[9:1]))
## Either as above (for factor 'z': using internal coding):
dd[ order(x, -y, z), ]
## or along 1st column, ties along 2nd, ... arbitrary* no. of columns:
dd[ do.call(order, dd), ]

set.seed(1) # reproducible example:
d4 <- data.frame(x = round(rnorm(100)), y = round(10*runif(100)),
    z = round(8*rnorm(100)), u = round(50*runif(100)))
(d4s <- d4[ do.call(order, d4), ])
(i <- which(diff(d4s[, 3]) == 0))
# in 2 places, needed 3 cols to break ties:
d4s[ rbind(i, i+1), ]

## rearrange matched vectors so that the first is in ascending order
x <- c(5:1, 6:8, 12:9)
y <- (x - 5)^2
o <- order(x)
rbind(x[o], y[o])

## tests of na.last
a <- c(4, 3, 2, NA, 1)
b <- c(4, NA, 2, 7, 1)
z <- cbind(a, b)
(o <- order(a, b)); z[o, ]
(o <- order(a, b, na.last = FALSE)); z[o, ]
(o <- order(a, b, na.last = NA)); z[o, ]

## speed examples on an average laptop for long vectors:
## factor/small-valued integers:
x <- factor(sample(letters, 1e7, replace = TRUE))
system.time(o <- sort.list(x, method = "quick", na.last = NA)) # 0.1 sec
stopifnot(!is.unsorted(x[o]))
system.time(o <- sort.list(x, method = "radix")); z[o, ]
## large-valued integers:
xx <- sample(1:200000, 1e7, replace = TRUE)
system.time(o <- sort.list(xx, method = "quick", na.last = NA)) # 0.3 sec
system.time(o <- sort.list(xx, method = "radix")) # 0.2 sec
## character vectors:
xx <- sample(state.name, 1e6, replace = TRUE)
system.time(o <- sort.list(xx, method = "shell")) # 2 sec
system.time(o <- sort.list(xx, method = "radix")) # 0.007 sec, 300X faster
## double vectors:
xx <- rnorm(1e6)
system.time(o <- sort.list(xx, method = "shell")) # 0.4 sec
system.time(o <- sort.list(xx, method = "quick", na.last = NA)) # 0.1 sec
system.time(o <- sort.list(xx, method = "radix")) # 0.05 sec, 2X faster

outer

Outer Product of Arrays
Description

The outer product of the arrays $X$ and $Y$ is the array $A$ with dimension $c(dim(X), \ dim(Y))$ where element $A[c(arrayindex.x, \ arrayindex.y)] = FUN(X[arrayindex.x], Y[arrayindex.y], ...)$.

Usage

```R
outer(X, Y, FUN = "*", ...)
X %o% Y
```

Arguments

- **X, Y**  
  First and second arguments for function FUN. Typically a vector or array.
- **FUN**  
  a function to use on the outer products, found via `match.fun` (except for the special case "*").
- **...**  
  optional arguments to be passed to FUN.

Details

$X$ and $Y$ must be suitable arguments for FUN. Each will be extended by `rep` to length the products of the lengths of $X$ and $Y$ before FUN is called.

FUN is called with these two extended vectors as arguments (plus any arguments in ...). It must be a vectorized function (or the name of one) expecting at least two arguments and returning a value with the same length as the first (and the second).

Where they exist, the `dim`names of $X$ and $Y$ will be copied to the answer, and a dimension assigned which is the concatenation of the dimensions of $X$ and $Y$ (or lengths if dimensions do not exist).

`FUN = "*"` is handled as a special case via `as.vector(X) %*% t(as.vector(Y))`, and is intended only for numeric vectors and arrays.

`%o%` is binary operator providing a wrapper for `outer(x, y, "*")`.

Examples

```R
x <- 1:9; names(x) <- x
# Multiplication & Power Tables
x %o% x
y <- 2:8; names(y) <- paste(y,".":", sep = "")
outer(y, x, "+")
```
outer(month.abb, 1999:2003, FUN = "paste")

## three way multiplication table:
x %o% x %o% y[1:3]

---

### Description

Open parenthesis, (, and open brace, {, are **Primitive** functions in R.

Effectively, ( is semantically equivalent to the identity function(x) x, whereas { is slightly more interesting, see examples.

### Usage

( ... )

{ ... }

### Value

For (, the result of evaluating the argument. This has visibility set, so will auto-print if used at top-level.

For {, the result of the last expression evaluated. This has the visibility of the last evaluation.

### References

### See Also

*if*, *return*, etc for other objects used in the R language itself.

**Syntax** for operator precedence.

### Examples

```r
f <- get(""

identical(f(e), e)

do <- get(""

do(x <- 3, y <- 2*x-3, 6-x-y); x; y

## note the differences
(2+3)
(2+3; 4+5)
(invisible(2+3))
(invisible(2+3))
```
parse

Parse Expressions

Description

parse returns the parsed but unevaluated expressions in a list.

Usage

parse(file = "", n = NULL, text = NULL, prompt = "?",
      keep.source = getOption("keep.source"), srcfile,
      encoding = "unknown")

Arguments

file a connection, or a character string giving the name of a file or a URL to read the expressions from. If file is "" and text is missing or NULL then input is taken from the console.
n integer (or coerced to integer). The maximum number of expressions to parse. If n is NULL or negative or NA the input is parsed in its entirety.
text character vector. The text to parse. Elements are treated as if they were lines of a file. Other R objects will be coerced to character if possible.
prompt the prompt to print when parsing from the keyboard. NULL means to use R's prompt, getOption("prompt").
keep.source a logical value; if TRUE, keep source reference information.
srcfile NULL, a character vector, or a srcfile object. See the 'Details' section.
encoding encoding to be assumed for input strings. If the value is "latin1" or "UTF-8" it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection con or via options(encoding=): see the example under file.

Details

If text has length greater than zero (after coercion) it is used in preference to file.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CR (as used on classic Mac OS). The final line can be incomplete, that is missing the final EOL marker.

When input is taken from the console, n = NULL is equivalent to n = 1, and n < 0 will read until an EOF character is read. (The EOF character is Ctrl-Z for the Windows front-ends.) The line-length limit is 4095 bytes when reading from the console (which may impose a lower limit: see 'An Introduction to R').

The default for srcfile is set as follows. If keep.source is not TRUE, srcfile defaults to a character string, either "<text>" or one derived from file. When keep.source is TRUE, if text is used, srcfile will be set to a srcfilecopy containing the text. If a character string is used for file, a srcfile object referring to that file will be used.

When srcfile is a character string, error messages will include the name, but source reference information will not be added to the result. When srcfile is a srcfile object, source reference information will be retained.
Value

An object of type "expression", with up to n elements if specified as a non-negative integer. When srcfile is non-NULL, a "srcref" attribute will be attached to the result containing a list of srcref records corresponding to each element, a "srcfile" attribute will be attached containing a copy of srcfile, and a "wholeSrcref" attribute will be attached containing a srcref record corresponding to all of the parsed text. Detailed parse information will be stored in the "srcfile" attribute, to be retrieved by `getParseData`.

A syntax error (including an incomplete expression) will throw an error. Character strings in the result will have a declared encoding if encoding is "latin1" or "UTF-8", or if text is supplied with every element of known encoding in a Latin-1 or UTF-8 locale.

Partial parsing

When a syntax error occurs during parsing, parse signals an error. The partial parse data will be stored in the srcfile argument if it is a srcfile object and the text argument was used to supply the text. In other cases it will be lost when the error is triggered.

The partial parse data can be retrieved using `getParseData` applied to the srcfile object. Because parsing was incomplete, it will typically include references to "parent" entries that are not present.

References

See Also

`scan`, `source`, `eval`, `deparse`.

The source reference information can be used for debugging (see e.g. `setBreakpoint`) and profiling (see `Rprof`). It can be examined by `getSrcref` and related functions. More detailed information is available through `getParseData`.

Examples

```r
  cat("x <- c(1, 4)\n x ^ 3 -10 ; outer(1:7, 5:9)\n", file = "xyz.Rdmped")
# parse 3 statements from the file "xyz.Rdmped"
parse(file = "xyz.Rdmped", n = 3)
unlink("xyz.Rdmped")

# A partial parse with a syntax error
txt <- "
  x <- 1
  an error"
sf <- srcfile("txt")
try(parse(text = txt, srcfile = sf))
getParseData(sf)
```
**Description**

Concatenate vectors after converting to character.

**Usage**

```r
paste (... , sep = " ", collapse = NULL)
paste0 (... , collapse = NULL)
```

**Arguments**

- `...` one or more R objects, to be converted to character vectors.
- `sep` a character string to separate the terms. Not `NA_character_`.
- `collapse` an optional character string to separate the results. Not `NA_character_`.

**Details**

`paste` converts its arguments (via `as.character`) to character strings, and concatenates them (separating them by the string given by `sep`). If the arguments are vectors, they are concatenated term-by-term to give a character vector result. Vector arguments are recycled as needed, with zero-length arguments being recycled to "".

Note that `paste()` coerces `NA_character_`, the character missing value, to "NA" which may seem undesirable, e.g., when pasting two character vectors, or very desirable, e.g. in `paste("the value of p is ", p)`.

`paste0(..., collapse)` is equivalent to `paste(..., sep = "", collapse)`, slightly more efficiently.

If a value is specified for `collapse`, the values in the result are then concatenated into a single string, with the elements being separated by the value of `collapse`.

**Value**

A character vector of the concatenated values. This will be of length zero if all the objects are, unless `collapse` is non-NULL in which case it is a single empty string.

If any input into an element of the result is in UTF-8 (and none are declared with encoding "bytes", see Encoding), that element will be in UTF-8, otherwise in the current encoding in which case the encoding of the element is declared if the current locale is either Latin-1 or UTF-8, at least one of the corresponding inputs (including separators) had a declared encoding and all inputs were either ASCII or declared.

If an input into an element is declared with encoding "bytes", no translation will be done of any of the elements and the resulting element will have encoding "bytes". If `collapse` is non-NULL, this applies also to the second, collapsing, phase, but some translation may have been done in pasting object together in the first phase.

**References**

Expand File Paths

Description

Expand a path name, for example by replacing a leading tilde by the user's home directory (if defined on that platform).

Usage

path.expand(path)
Arguments

path character vector containing one or more path names.

Details

(These details are for a Unix-alike: the details differ on Windows.)
On most builds of R a leading ~user will expand to the home directory of user, but not on builds
without readline installed. (In an interactive session capabilities("cledit") will report if
readline is available.)
The ‘path names’ need not exist nor be valid path names but they do need to be representable in the
session encoding.

Value

A character vector of possibly expanded path names: where the home directory is unknown or none
is specified the path is returned unchanged.

See Also

basename, normalizePath.

Examples

path.expand("~/foo")
pmatch

See Also

extSoftVersion for the PCRE version.

Examples

pcre_config()

pmatch Partial String Matching

Description

pmatch seeks matches for the elements of its first argument among those of its second.

Usage

pmatch(x, table, nomatch = NA_integer_, duplicates.ok = FALSE)

Arguments

x
the values to be matched: converted to a character vector by as.character. Long vectors are supported.

table
the values to be matched against: converted to a character vector. Long vectors are not supported.

nomatch
the value to be returned at non-matching or multiply partially matching positions. Note that it is coerced to integer.

duplicates.ok
should elements be in table be used more than once?

Details

The behaviour differs by the value of duplicates.ok. Consider first the case if this is true. First exact matches are considered, and the positions of the first exact matches are recorded. Then unique partial matches are considered, and if found recorded. (A partial match occurs if the whole of the element of x matches the beginning of the element of table.) Finally, all remaining elements of x are regarded as unmatched. In addition, an empty string can match nothing, not even an exact match to an empty string. This is the appropriate behaviour for partial matching of character indices, for example.

If duplicates.ok is FALSE, values of table once matched are excluded from the search for subsequent matches. This behaviour is equivalent to the R algorithm for argument matching, except for the consideration of empty strings (which in argument matching are matched after exact and partial matching to any remaining arguments).

charmatch is similar to pmatch with duplicates.ok true, the differences being that it differentiates between no match and an ambiguous partial match, it does match empty strings, and it does not allow multiple exact matches.

NA values are treated as if they were the string constant "NA".

Value

An integer vector (possibly including NA if nomatch = NA) of the same length as x, giving the indices of the elements in table which matched, or nomatch.
References

See Also

`match`, `charmatch` and `match.arg`, `match.fun`, `match.call`, for function argument matching etc.,
`startsWith` for particular checking of initial matches; `grep` etc for more general (regexp) matching
of strings.

Examples

```r
pmatch("", ") # returns NA
pmatch("m", c("mean", "median", "mode")) # returns NA
pmatch("md", c("mean", "median", "mode")) # returns 2

pmatch(c("", "ab", "ab"), c("abc", "ab"), dup = FALSE)
pmatch(c("", "ab", "ab"), c("abc", "ab"), dup = TRUE)
## compare
charmatch(c("", "ab", "ab"), c("abc", "ab"))
```

polyroot

*Find Zeros of a Real or Complex Polynomial*

Description

Find zeros of a real or complex polynomial.

Usage

`polyroot(z)`

Arguments

`z` the vector of polynomial coefficients in increasing order.

Details

A polynomial of degree \( n - 1 \),

\[
p(x) = z_1 + z_2x + \cdots + z_nx^{n-1}
\]

is given by its coefficient vector `z[1:n]`. `polyroot` returns the \( n - 1 \) complex zeros of \( p(x) \) using the Jenkins-Traub algorithm.

If the coefficient vector `z` has zeroes for the highest powers, these are discarded.

There is no maximum degree, but numerical stability may be an issue for all but low-degree polynomials.

Value

A complex vector of length \( n - 1 \), where \( n \) is the position of the largest non-zero element of `z`. 
Source
C translation by Ross Ihaka of Fortran code in the reference, with modifications by the R Core Team.

References

uniroot for numerical root finding of arbitrary functions; complex and the zero example in the demos directory.

Examples
polyroot(c(1, 2, 1))
round(polyroot(choose(8, 0:8)), 11) # guess what!
for (n1 in 1:4) print(polyroot(1:n1), digits = 4)
polyroot(c(1, 2, 1, 0, 0)) # same as the first

---

pos.to.env

**Convert Positions in the Search Path to Environments**

Description
Returns the environment at a specified position in the search path.

Usage
pos.to.env(x)

Arguments
x an integer between 1 and length(search()), the length of the search path, or -1.

Details
Several R functions for manipulating objects in environments (such as get and ls) allow specifying environments via corresponding positions in the search path. pos.to.env is a convenience function for programmers which converts these positions to corresponding environments; users will typically have no need for it. It is primitive.

-1 is interpreted as the environment the function is called from.
This is a primitive function.

Examples
pos.to.env(1) # R_GlobalEnv
# the next returns the base environment
pos.to.env(length(search()))
pretty

Pretty Breakpoints

Description

Compute a sequence of about \(n+1\) equally spaced ‘round’ values which cover the range of the values in \(x\). The values are chosen so that they are 1, 2 or 5 times a power of 10.

Usage

pretty(x, ...)

## Default S3 method:
pretty(x, \(n = 5\), \(\text{min.n} = n \%\% 3\), \(\text{shrink.sml} = 0.75\),
\(\text{high.u.bias} = 1.5\), \(\text{u5.bias} = .5 + 1.5*\text{high.u.bias}\),
\(\text{eps.correct} = 0\), ...)

Arguments

\(x\) an object coercible to numeric by \code{as.numeric}.
\(n\) integer giving the \emph{desired} number of intervals. Non-integer values are rounded down.
\(\text{min.n}\) nonnegative integer giving the \emph{minimal} number of intervals. If \(\text{min.n} = 0\), pretty(.) may return a single value.
\(\text{shrink.sml}\) positive numeric by a which a default scale is shrunk in the case when \(\text{range}(x)\) is very small (usually 0).
\(\text{high.u.bias}\) non-negative numeric, typically > 1. The interval unit is determined as \{1,2,5,10\} times \(b\), a power of 10. Larger \(\text{high.u.bias}\) values favor larger units.
\(\text{u5.bias}\) non-negative numeric multiplier favoring factor 5 over 2. Default and ‘optimal’: \(\text{u5.bias} = .5 + 1.5*\text{high.u.bias}\).
\(\text{eps.correct}\) integer code, one of \{0,1,2\}. If non-0, an \emph{epsilon correction} is made at the boundaries such that the result boundaries will be outside \(\text{range}(x)\); in the \emph{small} case, the correction is only done if \(\text{eps.correct} \geq 2\).

... further arguments for methods.

Details

pretty ignores non-finite values in \(x\).

Let \(d \leftarrow \max(x) - \min(x) \geq 0\). If \(d\) is not (very close) to 0, we let \(c \leftarrow d/n\), otherwise more or less \(c \leftarrow \max(\text{abs}(\text{range}(x)))\times\text{shrink.sml} / \text{min.n}\). Then, the \emph{10 base} \(b\) is \(10^{\left\lfloor \log_{10}(c) \right\rfloor}\) such that \(b \leq c < 10b\).

Now determine the basic \emph{unit} \(u\) as one of \{1,2,5,10\}\(b\), depending on \(c/b \in [1,10]\) and the two ‘bias’ coefficients, \(h =\text{high.u.bias}\) and \(f =\text{u5.bias}\).
References

axTicks for the computation of pretty axis tick locations in plots, particularly on the log scale.

Examples

```r
pretty(1:15)  # 0  2  4  6  8 10 12 14 16 18
pretty(1:15, h = 2)  # 0  5 10 15 20
pretty(1:15, n = 4)  # 0  5 10 15 20 25 30
pretty(1:20)  # 0  5 10 15 20 25 30 35
pretty(1:20, n = 2) # 0 10 20 30 40
pretty(1:20, n = 10)  # 0  2  4  ... 20

for(k in 5:11) {
cat("k=", k, ": "); print(diff(range(pretty(100 + c(0, pi*10^-k)))))
}
```

##-- more bizarre, when min(x) == max(x):

```r
pretty(pi)
```

```r
add.names <- function(v) { names(v) <- paste(v); v}
utils::str(lapply(add.names(-10:20), pretty))
```

```r
utils::str(lapply(add.names(0:20), pretty, min.n = 0))
```

```r
sapply( add.names(0:20), pretty, min.n = 4)
```

```r
pretty(1.234e100)
```

```r
pretty(1001.1001)
```

```r
pretty(1001.1001, shrink = 0.2)
```

```r
for(k in -7:3)
cat("shrink=", formatC(2^k, width = 9),": ",
    formatC(pretty(1001.1001, shrink.sml = 2^k), width = 6),"\n")
```

---

**Primitive**

Look Up a Primitive Function

Description

.Primitive looks up by name a 'primitive' (internally implemented) function.

Usage

.Primitive(name)

Arguments

name  name of the R function.
Details

The advantage of .Primitive over .Internal functions is the potential efficiency of argument passing, and that positional matching can be used where desirable, e.g. in switch. For more details, see the 'R Internals Manual'.

All primitive functions are in the base namespace.

This function is almost never used: `name` or, more carefully, `get(name, envir = baseenv())` work equally well and do not depend on knowing which functions are primitive (which does change as R evolves).

See Also

.Internal.

Examples

```r
mysqrt <- .Primitive("sqrt")
c
.Internal # this one *must* be primitive!
`if` # need backticks
```

---

print

Print Values

Description

print prints its argument and returns it invisibly (via invisible(x)). It is a generic function which means that new printing methods can be easily added for new classes.

Usage

```r
print(x, ...)  
## S3 method for class 'factor'
print(x, quote = FALSE, max.levels = NULL, width = getOption("width"), ...)

## S3 method for class 'table'
print(x, digits = getOption("digits"), quote = FALSE, 
na.print = "", zero.print = "0", 
right = is.numeric(x) || is.complex(x), 
justify = "none", ...)

## S3 method for class 'function'
print(x, useSource = TRUE, ...)
```

Arguments

- `x` an object used to select a method.
- `...` further arguments passed to or from other methods.
quote logical, indicating whether or not strings should be printed with surrounding quotes.

max.levels integer, indicating how many levels should be printed for a factor; if 0, no extra "Levels" line will be printed. The default, NULL, entails choosing max.levels such that the levels print on one line of width width.

width only used when max.levels is NULL, see above.

digits minimal number of significant digits, see print.default.

na.print character string (or NULL) indicating NA values in printed output, see print.default.

zero.print character specifying how zeros (0) should be printed; for sparse tables, using "." can produce more readable results, similar to printing sparse matrices in Matrix.

right logical, indicating whether or not strings should be right aligned.

justify character indicating if strings should left- or right-justified or left alone, passed to format.

useSource logical indicating if internally stored source should be used for printing when present, e.g., if options(keep.source = TRUE) has been in use.

Details

The default method, print.default has its own help page. Use methods("print") to get all the methods for the print generic.

print.factor allows some customization and is used for printing ordered factors as well.

print.table for printing tables allows other customization. As of R 3.0.0, it only prints a description in case of a table with 0-extents (this can happen if a classifier has no valid data).

See noquote as an example of a class whose main purpose is a specific print method.

References

See Also

The default method print.default, and help for the methods above; further options, noquote.

For more customizable (but cumbersome) printing, see cat, format or also write. For a simple prototypical print method, see .print.via.format in package tools.

Examples

require(stats)

#-- print is the "Default function" --> print.ts(.) is called
for(i in 1:3) print(1:i)

## Printing of factors
attenu$station ## 117 levels -> 'max.levels' depending on width

## ordered factors: levels "11 < 12 < .."
esoph$agegp[1:12]
esoph$alcgp[1:12]
## Printing of sparse (contingency) tables

```r
set.seed(521)
t1 <- round(abs(rt(200, df = 1.8)))
t2 <- round(abs(rt(200, df = 1.4)))
table(t1, t2) # simple
print(table(t1, t2), zero.print = ".") # nicer to read

## same for non-integer "table":
T <- table(t2,t1)
T <- T * (1+round(rlnorm(length(T)))/4)
print(T, zero.print = ".") # quite nicer,
print.table(T[,2:8] * 1e9, digits=3, zero.print = ".")
## still slightly inferior to Matrix::Matrix(T) for larger T

## Corner cases with empty extents:
table(1, NA) # < table of extent 1 x 0 >
```

### print.data.frame

**Printing Data Frames**

**Description**

Print a data frame.

**Usage**

```r
## S3 method for class 'data.frame'
print(x, ..., digits = NULL,
quote = FALSE, right = TRUE, row.names = TRUE)
```

**Arguments**

- `x`: object of class `data.frame`.
- `...`: optional arguments to `print` or `plot` methods.
- `digits`: the minimum number of significant digits to be used: see `print.default`.
- `quote`: logical, indicating whether or not entries should be printed with surrounding quotes.
- `right`: logical, indicating whether or not strings should be right-aligned. The default is right-alignment.
- `row.names`: logical (or character vector), indicating whether (or what) row names should be printed.

**Details**

This calls `format` which formats the data frame column-by-column, then converts to a character matrix and dispatches to the `print` method for matrices.

When `quote = TRUE` only the entries are quoted not the row names nor the column names.

**See Also**

`data.frame`. 
print.default

Examples

(dd <- data.frame(x = 1:8, f = gl(2,4), ch = I(letters[1:8])))
  # print() with defaults
  print(dd, quote = TRUE, row.names = FALSE)
  # suppresses row.names and quotes all entries

print.default

Default Printing

Description

print.default is the default method of the generic print function which prints its argument.

Usage

## Default S3 method:
print(x, digits = NULL, quote = TRUE,
  na.print = NULL, print.gap = NULL, right = FALSE,
  max = NULL, useSource = TRUE, ...)

Arguments

x
  the object to be printed.

digits
  a non-null value for digits specifies the minimum number of significant digits to be printed in values. The default, NULL, uses getOption("digits"). (For the interpretation for complex numbers see signif.) Non-integer values will be rounded down, and only values greater than or equal to 1 and no greater than 22 are accepted.

quote
  logical, indicating whether or not strings (characters) should be printed with surrounding quotes.

na.print
  a character string which is used to indicate NA values in printed output, or NULL (see ‘Details’).

print.gap
  a non-negative integer ≤ 1024, or NULL (meaning 1), giving the spacing between adjacent columns in printed vectors, matrices and arrays.

right
  logical, indicating whether or not strings should be right aligned. The default is left alignment.

max
  a non-null value for max specifies the approximate maximum number of entries to be printed. The default, NULL, uses getOption("max.print"); see that help page for more details.

useSource
  logical, indicating whether to use source references or copies rather than deparsing language objects. The default is to use the original source if it is available.

...

  further arguments to be passed to or from other methods. They are ignored in this function.
print.default

Details

The default for printing NAs is to print `NA` (without quotes) unless this is a character `NA` and `quote = FALSE`, when `<NA>` is printed.

The same number of decimal places is used throughout a vector. This means that `digits` specifies the minimum number of significant digits to be used, and that at least one entry will be encoded with that minimum number. However, if all the encoded elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit. Decimal points are only included if at least one decimal place is selected.

Attributes are printed respecting their class(es), using the values of `digits` to `print.default`, but using the default values (for the methods called) of the other arguments.

Option `width` controls the printing of vectors, matrices and arrays, and option `deparse.cutoff` controls the printing of language objects such as calls and formulae.

When the `methods` package is attached, `print` will call `show` for R objects with formal classes if called with no optional arguments.

Large number of digits

Note that for large values of `digits`, currently for `digits >= 16`, the calculation of the number of significant digits will depend on the platform’s internal (C library) implementation of ‘`sprintf()`’ functionality.

Single-byte locales

If a non-printable character is encountered during output, it is represented as one of the ANSI escape sequences (`\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, `\` and `\0`: see Quotes), or failing that as a 3-digit octal code: for example the UK currency pound sign in the C locale (if implemented correctly) is printed as `\243`. Which characters are non-printable depends on the locale. (Because some versions of Windows get this wrong, all bytes with the upper bit set are regarded as printable on Windows in a single-byte locale.)

Unicode and other multi-byte locales

In all locales, the characters in the ASCII range (`\0x00` to `\0x7f`) are printed in the same way, as-is if printable, otherwise via ANSI escape sequences or 3-digit octal escapes as described for single-byte locales.

Multi-byte non-printing characters are printed as an escape sequence of the form `\uxxxxx` or `\Uxxxxxxxx` (in hexadecimal). This is the internal code for the wide-character representation of the character. If this is not known to be Unicode code points, a warning is issued. The only known exceptions are certain Japanese ISO 2022 locales on commercial Unixes, which use a concatenation of the bytes: it is unlikely that R compiles on such a system.

It is possible to have a character string in a character vector that is not valid in the current locale. If a byte is encountered that is not part of a valid character it is printed in hex in the form `\xabb` and this is repeated until the start of a valid character. (This will rapidly recover from minor errors in UTF-8.)

See Also

The generic `print`, `options`. The `"noquote"` class and print method.

`encodeString`, which encodes a character vector the way it would be printed.
Examples

pi
print(pi, digits = 16)
LETTERS[1:16]
print(LETTERS, quote = FALSE)

M <- cbind(I = 1, matrix(1:10000, ncol = 10,
                   dimnames = list(NULL, LETTERS[1:10])))
utils::head(M)    # makes more sense than
print(M, max = 1000)  # prints 90 rows and a message about omitting 910

prmatrix

Print Matrices, Old-style

Description

An earlier method for printing matrices, provided for S compatibility.

Usage

prmatrix(x, rowlab =, collab =,
         quote = TRUE, right = FALSE, na.print = NULL, ...)

Arguments

x    numeric or character matrix.
rowlab, collab  (optional) character vectors giving row or column names respectively. By de-
                 fault, these are taken from dimnames(x).
quote  logical; if TRUE and x is of mode "character", quotes (""') are used.
right  if TRUE and x is of mode "character", the output columns are right-justified.
na.print how NAs are printed. If this is non-null, its value is used to represent NA.
...    arguments for print methods.

Details

prmatrix is an earlier form of print.matrix, and is very similar to the S function of the same
name.

Value

Invisibly returns its argument, x.

References

Brooks/Cole.

See Also

print.default, and other print methods.
Examples

```r
prmatrix(m6 <- diag(6), rowlab = rep("", 6), collab = rep("", 6))
chm <- matrix(scan(system.file("help", "AnIndex", package = "splines"),
       what = ""), , 2, byrow = TRUE)
chm # uses print.matrix()
prmatrix(chm, collab = paste("Column", 1:3), right = TRUE, quote = FALSE)
```

Description

`proc.time` determines how much real and CPU time (in seconds) the currently running R process has already taken.

Usage

`proc.time()`

Details

`proc.time` returns five elements for backwards compatibility, but its `print` method prints a named vector of length 3. The first two entries are the total user and system CPU times of the current R process and any child processes on which it has waited, and the third entry is the ‘real’ elapsed time since the process was started.

Value

An object of class "proc_time" which is a numeric vector of length 5, containing the user, system, and total elapsed times for the currently running R process, and the cumulative sum of user and system times of any child processes spawned by it on which it has waited. (The `print` method uses the `summary` method to combine the child times with those of the main process.)

The resolution of the times will be system-specific and on Unix-alikes times are rounded down to milliseconds. On modern systems they will be that accurate, but on older systems they might be accurate to 1/100 or 1/60 sec. They are typically available to 10ms on Windows.

The definition of ‘user’ and ‘system’ times is from your OS. Typically it is something like

The ‘user time’ is the CPU time charged for the execution of user instructions of the calling process. The ‘system time’ is the CPU time charged for execution by the system on behalf of the calling process.

Times of child processes are not available on Windows and will always be given as NA.

This is a primitive function.

References

prod

See Also

system.time for timing an R expression, gc.time for how much of the time was spent in garbage collection.

Examples

## a way to time an R expression: system.time is preferred
ptm <- proc.time()
for (i in 1:50) mad(stats::.runif(500))
proc.time() - ptm

prod

Product of Vector Elements

Description

prod returns the product of all the values present in its arguments.

Usage

prod(..., na.rm = FALSE)

Arguments

... numeric or complex or logical vectors.
na.rm logical. Should missing values be removed?

Details

If na.rm is FALSE an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

This is a generic function: methods can be defined for it directly or via the Summary group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

Logical true values are regarded as one, false values as zero. For historical reasons, NULL is accepted and treated as if it were numeric(0).

Value

The product, a numeric (of type "double") or complex vector of length one. NB: the product of an empty set is one, by definition.

S4 methods

This is part of the S4 Summary group generic. Methods for it must use the signature x, ..., na.rm.

References

prop.table

Express Table Entries as Fraction of Marginal Table

Description

This is really sweep(x, margin, margin.table(x, margin), "/") for newbies, except that if margin has length zero, then one gets $x/\text{sum}(x)$.

Usage

prop.table(x, margin = NULL)

Arguments

x table

margin index, or vector of indices to generate margin for

Value

Table like x expressed relative to margin

Author(s)

Peter Dalgaard

See Also

margin.table

Examples

m <- matrix(1:4, 2)
m
prop.table(m, 1)
pushBack

Push Text Back on to a Connection

Description
Functions to push back text lines onto a connection, and to enquire how many lines are currently pushed back.

Usage
```r
clearPushBack(connection)
pushBack(data, connection, newLine = TRUE, encoding = c("", "bytes", "UTF-8")) pushBackLength(connection)
```

Arguments
data  a character vector.
connection  A connection.
newLine  logical. If true, a newline is appended to each string pushed back.
encoding  character string, partially matched. See details.

Details
Several character strings can be pushed back on one or more occasions. The occasions form a stack, so the first line to be retrieved will be the first string from the last call to `pushBack`. Lines which are pushed back are read prior to the normal input from the connection, by the normal text-reading functions such as `readLines` and `scan`.

Pushback is only allowed for readable connections in text mode.

Not all uses of connections respect pushbacks, in particular the input connection is still wired directly, so for example parsing commands from the console and `scan(""")` ignore pushbacks on `stdin`.

When character strings with a marked encoding (see `Encoding`) are pushed back they are converted to the current encoding if `encoding = ""`. This may involve representing characters as `\n\uXXXX` if they cannot be converted. They will be converted to UTF-8 if `encoding = "UTF-8"` or left as-is if `encoding = "bytes"`.

Value
*pushBack* and `clearPushBack()` return nothing, invisibly.

*pushBackLength* returns the number of lines currently pushed back.

See Also
`connections, readLines`
Examples

```r
zz <- textConnection(LETTERS)
readLines(zz, 2)
pushBack(c("aa", "bb"), zz)
pushBackLength(zz)
readLines(zz, 1)
pushBackLength(zz)
readLines(zz, 1)
readLines(zz, 1)
close(zz)
```

---

qr

The QR Decomposition of a Matrix

Description

qr computes the QR decomposition of a matrix.

Usage

```r
qr(x, ...)
## Default S3 method:
qr(x, tol = 1e-07, LAPACK = FALSE, ...)
```

```r
qr.coef(qr, y)
qr.qy(qr, y)
qr.qty(qr, y)
qr.resid(qr, y)
qr.fitted(qr, y, k = qr$rank)
qr.solve(a, b, tol = 1e-7)
## S3 method for class 'qr'
solve(a, b, ...)
```

```r
is.qr(x)
as.qr(x)
```

Arguments

- **x**: a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.
- **tol**: the tolerance for detecting linear dependencies in the columns of `x`. Only used if LAPACK is false and `x` is real.
- **qr**: a QR decomposition of the type computed by `qr`.
- **y, b**: a vector or matrix of right-hand sides of equations.
- **a**: a QR decomposition or (`qr.solve` only) a rectangular matrix.
- **k**: effective rank.
- **LAPACK**: logical. For real `x`, if true use LAPACK otherwise use LINPACK (the default).
- **...**: further arguments passed to or from other methods.
The QR decomposition plays an important role in many statistical techniques. In particular it can be used to solve the equation \( Ax = b \) for given matrix \( A \), and vector \( b \). It is useful for computing regression coefficients and in applying the Newton-Raphson algorithm.

The functions \( \text{qr.coef} \), \( \text{qr.resid} \), and \( \text{qr.fitted} \) return the coefficients, residuals and fitted values obtained when fitting \( y \) to the matrix with QR decomposition \( \text{qr} \). (If pivoting is used, some of the coefficients will be \( \text{NA} \).) \( \text{qr.qy} \) and \( \text{qr.qty} \) return \( Q \%\times\% y \) and \( t(Q) \%\times\% y \), where \( Q \) is the (complete) \( Q \) matrix.

All the above functions keep dimnames (and names) of \( x \) and \( y \) if there are any.

\( \text{solve.qr} \) is the method for \( \text{solve} \) for \( \text{qr} \) objects. \( \text{qr.solve} \) solves systems of equations via the QR decomposition: if \( a \) is a QR decomposition it is the same as \( \text{solve.qr} \), but if \( a \) is a rectangular matrix the QR decomposition is computed first. Either will handle over- and under-determined systems, providing a least-squares fit if appropriate.

\( \text{is.qr} \) returns \( \text{TRUE} \) if \( x \) is a \text{list} and \text{inherits} from "\text{qr}".

It is not possible to coerce objects to mode "\text{qr}". Objects either are QR decompositions or they are not.

The LINPACK interface is restricted to matrices \( x \) with less than \( 2^{31} \) elements.
\( \text{qr.fitted} \) and \( \text{qr.resid} \) only support the LINPACK interface.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

### Value

The QR decomposition of the matrix as computed by LINPACK(*) or LAPACK. The components in the returned value correspond directly to the values returned by DQRDC(2)/DGEQP3/ZGEQP3.

- \( \text{qr} \): a matrix with the same dimensions as \( x \). The upper triangle contains the \( R \) of the decomposition and the lower triangle contains information on the \( Q \) of the decomposition (stored in compact form). Note that the storage used by DQRDC and DGEQP3 differs.
- \( \text{qraux} \): a vector of length \( \text{ncol}(x) \) which contains additional information on \( Q \).
- \( \text{rank} \): the rank of \( x \) as computed by the decomposition(*): always full rank in the LAPACK case.
- \( \text{pivot} \): information on the pivoting strategy used during the decomposition.

Non-complex QR objects computed by LAPACK have the attribute "useLAPACK" with value \( \text{TRUE} \).

*) \( \text{dqrdc2} \) instead of LINPACK’s DQRDC

In the (default) LINPACK case (\( \text{LAPACK} = \text{FALSE} \)), \( \text{qr}() \) uses a modified version of LINPACK’s DQRDC, called ‘\( \text{dqrdc2} \)’. It differs by using the tolerance \( \text{tol} \) for a pivoting strategy which moves columns with near-zero 2-norm to the right-hand edge of the \( x \) matrix. This strategy means that sequential one degree-of-freedom effects can be computed in a natural way.

### Note

To compute the determinant of a matrix (do you really need it?), the QR decomposition is much more efficient than using Eigen values (\( \text{eigen} \)). See \( \text{det} \).

Using LAPACK (including in the complex case) uses column pivoting and does not attempt to detect rank-deficient matrices.
Source

For `qr`, the LINPACK routine DQRDC (but modified to dqrdc2(*)) and the LAPACK routines DGEQP3 and ZGEQP3. Further LINPACK and LAPACK routines are used for `qr.coef`, `qr.qy` and `qr.aty`.

LAPACK and LINPACK are from [http://www.netlib.org/lapack](http://www.netlib.org/lapack) and [http://www.netlib.org/linpack](http://www.netlib.org/linpack) and their guides are listed in the references.

`det` (using `qr`) to compute the determinant of a matrix.

Examples

```r
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
h9 <- hilbert(9); h9
qr(h9)$rank; qr(h9, tol = 1e-10)$rank

##-- Solve linear equation system H %*% x = y :
y <- 1:9/10
x <- qr.solve(h9, y, tol = 1e-10) # or equivalently :
x <- qr.coef(qrh9, y) #-- is == but much better than
  #-- solve(h9) %*% y
h9 %*% x # = y

## overdetermined system
A <- matrix(rnorm(12), 4)
b <- 1:4
qr.solve(A, b) # or solve(qr(A), b)
solve(qr(A, LAPACK = TRUE), b)
  # this is a least-squares solution, cf. lm(b ~ 0 + A)

## underdetermined system
A <- matrix(rnorm(12), 3)
b <- 1:3
qr.solve(A, b)
solve(qr(A, LAPACK = TRUE), b)
  # solutions will have one zero, not necessarily the same one
```
Reconstruct the Q, R, or X Matrices from a QR Object

Description

Returns the original matrix from which the object was constructed or the components of the decomposition.

Usage

qr.X(qr, complete = FALSE, ncol =)
qr.Q(qr, complete = FALSE, Dvec =)
qr.R(qr, complete = FALSE)

Arguments

qr
object representing a QR decomposition. This will typically have come from a previous call to qr or lsfit.

complete
logical expression of length 1. Indicates whether an arbitrary orthogonal completion of the Q or X matrices is to be made, or whether the R matrix is to be completed by binding zero-value rows beneath the square upper triangle.

ncol
integer in the range 1:nrow(qr$qr). The number of columns to be in the reconstructed X. The default when complete is FALSE is the first min(ncol(X), nrow(X)) columns of the original X from which the qr object was constructed. The default when complete is TRUE is a square matrix with the original X in the first ncol(X) columns and an arbitrary orthogonal completion (unitary completion in the complex case) in the remaining columns.

Dvec
vector (not matrix) of diagonal values. Each column of the returned Q will be multiplied by the corresponding diagonal value. Defaults to all 1s.

Value

qr.X returns X, the original matrix from which the qr object was constructed, provided ncol(X) <= nrow(X). If complete is TRUE or the argument ncol is greater than ncol(X), additional columns from an arbitrary orthogonal (unitary) completion of X are returned.

qr.Q returns part or all of Q, the order-nrow(X) orthogonal (unitary) transformation represented by qr. If complete is TRUE, Q has nrow(X) columns. If complete is FALSE, Q has ncol(X) columns. When Dvec is specified, each column of Q is multiplied by the corresponding value in Dvec.

Note that qr.Q(qr, *) is a special case of qr.qy(qr, y) (with a “diagonal” y), and qr.X(qr, *) is basically qr.qy(qr, R) (apart from pivoting and dimnames setting).

qr.R returns R. This may be pivoted, e.g., if a <- qr(x) then x[, a$pivot] = QR. The number of rows of R is either nrow(X) or ncol(X) (and may depend on whether complete is TRUE or FALSE).

See Also

qr, qr.qy.
Examples

```r
p <- ncol(x <- LifeCycleSavings[, -1]) # not the 'sr'
qrstr <- qr(x) # dim(x) == c(n,p)
qrstr $ rank # = 4 = p
Q <- qr.Q(qrstr) # dim(Q) == dim(x)
R <- qr.R(qrstr) # dim(R) == ncol(x)
X <- qr.X(qrstr) # X == x
range(X - as.matrix(x)) # ~ < 6e-12
## X == Q %*% R if there has been no pivoting, as here:
all.equal(unname(X),
          unname(Q %*% R))

# example of pivoting
x <- cbind(int = 1,
            b1 = rep(1:0, each = 3),
            c1 = rep(c(1,0,0), 2),
            b2 = rep(0:1, each = 3),
            c2 = rep(c(0,1,0), 2),
            c3 = rep(c(0,0,1),2))
x # is singular, columns "b2" and "c3" are "extra"
a <- qr(x)
zapsmall(qr.R(a)) # columns are int b1 c1 c2 b2 c3
d <- pivI <- sort.list(a$pivot) # the inverse permutation
all.equal(x,
          qr.Q(a) %*% qr.R(a)) # no, no
stopifnot(
          all.equal(x[, a$pivot], qr.Q(a) %*% qr.R(a)), # TRUE
          all.equal(x, qr.Q(a) %*% qr.R(a)[, pivI])) # TRUE too!
```

Description

The function `quit` or its alias `q` terminate the current R session.

Usage

```r
quit(save = "default", status = 0, runLast = TRUE)
q(save = "default", status = 0, runLast = TRUE)
```

Arguments

- `save`: a character string indicating whether the environment (workspace) should be saved, one of "no", "yes", "ask" or "default".
- `status`: the (numerical) error status to be returned to the operating system, where relevant. Conventionally 0 indicates successful completion.
- `runLast`: should `.Last()` be executed?

Details

`save` must be one of "no", "yes", "ask" or "default". In the first case the workspace is not saved, in the second it is saved and in the third the user is prompted and can also decide not to quit. The default is to ask in interactive use but may be overridden by command-line arguments (which must be supplied in non-interactive use).
Immediately before normal termination, \code{.Last()} is executed if the function \code{.Last} exists and \code{runLast} is true. If in interactive use there are errors in the \code{.Last} function, control will be returned to the command prompt, so do test the function thoroughly. There is a system analogue, \code{.Last.sys()}, which is run after \code{.Last()} if \code{runLast} is true.

Exactly what happens at termination of an \proglang{R} session depends on the platform and GUI interface in use. A typical sequence is to run \code{.Last()} and \code{.Last.sys()} (unless \code{runLast} is false), to save the workspace if requested (and in most cases also to save the session history: see \code{savehistory}), then run any finalizers (see \code{reg.finalizer}) that have been set to be run on exit, close all open graphics devices, remove the session temporary directory and print any remaining warnings (e.g., from \code{.Last()} and device closure).

Some error status values are used by \proglang{R} itself. The default error handler for non-interactive use effectively calls \code{q("no", 1, FALSE)} and returns error status 1. Error status 2 is used for \proglang{R} ‘suicide’, that is a catastrophic failure, and other small numbers are used by specific ports for initialization failures. It is recommended that users choose statuses of 10 or more.

Valid values of \code{status} are system-dependent, but 0:255 are normally valid. (Many OSes will report the last byte of the value, that is report the value modulo 256. But not all.)

### Warning

The value of \code{.Last} is for the end user to control: as it can be replaced later in the session, it cannot safely be used programmatically, e.g. by a package. The other way to set code to be run at the end of the session is to use a \code{finalizer}: see \code{reg.finalizer}.

### Note

The \proglang{R.app} GUI on macOS has its own version of these functions with slightly different behaviour for the \code{save} argument (the GUI’s ‘Startup’ preferences for this action are taken into account).

### References

### See Also

\code{.First} for setting things on startup.

### Examples

```r
## Not run: ## Unix-flavour example
.Last <- function() {
  graphics.off() # close devices before printing
  cat("Now sending PDF graphics to the printer:\n")
  system("lpr Rplots.pdf")
  cat("bye bye...\n")
}
quit("yes")
## End(Not run)
```
Description

Descriptions of the various uses of quoting in R.

Details

Three types of quotes are part of the syntax of R: single and double quotation marks and the backtick (or back quote, ‘‘‘). In addition, backslash is used to escape the following character inside character constants.

Character constants

Single and double quotes delimit character constants. They can be used interchangeably but double quotes are preferred (and character constants are printed using double quotes), so single quotes are normally only used to delimit character constants containing double quotes.

Backslash is used to start an escape sequence inside character constants. Escaping a character not in the following table is an error.

Single quotes need to be escaped by backslash in single-quoted strings, and double quotes in double-quoted strings.

<table>
<thead>
<tr>
<th>Escape</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>‘\n’</td>
<td>newline</td>
</tr>
<tr>
<td>‘\r’</td>
<td>carriage return</td>
</tr>
<tr>
<td>‘\t’</td>
<td>tab</td>
</tr>
<tr>
<td>‘\b’</td>
<td>backspace</td>
</tr>
<tr>
<td>‘\a’</td>
<td>alert (bell)</td>
</tr>
<tr>
<td>‘\f’</td>
<td>form feed</td>
</tr>
<tr>
<td>‘\v’</td>
<td>vertical tab</td>
</tr>
<tr>
<td>‘\’</td>
<td>backslash ‘\’</td>
</tr>
<tr>
<td>‘\’</td>
<td>ASCII apostrophe ‘’</td>
</tr>
<tr>
<td>‘\’</td>
<td>ASCII quotation mark ‘’</td>
</tr>
<tr>
<td>‘\’</td>
<td>ASCII grave accent (backtick) ‘’</td>
</tr>
<tr>
<td>‘\nn’</td>
<td>character with given octal code (1, 2 or 3 digits)</td>
</tr>
<tr>
<td>‘\nnn’</td>
<td>character with given hex code (1 or 2 hex digits)</td>
</tr>
<tr>
<td>‘\uxxxx’</td>
<td>Unicode character with given code (1–4 hex digits)</td>
</tr>
<tr>
<td>‘\Uxxxxxxxx’</td>
<td>Unicode character with given code (1–8 hex digits)</td>
</tr>
</tbody>
</table>

Alternative forms for the last two are ‘\u(\n\n)’ and ‘\U(\n\n\n\n)’. All except the Unicode escape sequences are also supported when reading character strings by scan and read.table if allowEscapes = TRUE. Unicode escapes can be used to enter Unicode characters not in the current locale’s charset (when the string will be stored internally in UTF-8).

The parser does not allow the use of both octal/hex and Unicode escapes in a single string.

These forms will also be used by print.default when outputting non-printable characters (including backslash).

Embedded nuls are not allowed in character strings, so using escapes (such as ‘\0’) for a nul will result in the string being truncated at that point (usually with a warning).
Names and Identifiers

Identifiers consist of a sequence of letters, digits, the period (.) and the underscore. They must not start with a digit nor underscore, nor with a period followed by a digit. Reserved words are not valid identifiers.

The definition of a letter depends on the current locale, but only ASCII digits are considered to be digits.

Such identifiers are also known as syntactic names and may be used directly in R code. Almost always, other names can be used provided they are quoted. The preferred quote is the backtick (``), and deparse will normally use it, but under many circumstances single or double quotes can be used (as a character constant will often be converted to a name). One place where backticks may be essential is to delimit variable names in formulae: see formula.

See Also

Syntax for other aspects of the syntax.
sQuote for quoting English text.
shQuote for quoting OS commands.
The ‘R Language Definition’ manual.

Examples

'single quotes can be used more-or-less interchangeably'
"with double quotes to create character vectors"

## Single quotes inside single-quoted strings need backslash-escaping.
## Ditto double quotes inside double-quoted strings.
##
identical("It's alive!", he screamed.,
    "\"It's alive\"!", he screamed.") # same

## Backslashes need doubling, or they have a special meaning.
x <- "In ALGOL, you could do logical AND with /\.
print(x)       # shows it as above ("input-like")
writeLines(x) # shows it as you like it ;-) 

## Single backslashes followed by a letter are used to denote
## special characters like tab(ulator)s and newlines:
x <- "long\lines can be\nbroken with newlines"
writeLines(x) # see also ?strwrap

## Backticks are used for non-standard variable names.
## (See make.names and ?Reserved for what counts as
## non-standard.)
x y <- 1:5
x y

d <- data.frame('1st column' = rchisq(5, 2), check.names = FALSE)
d$'1st column'

## Backslashes followed by up to three numbers are interpreted as
## octal notation for ASCII characters.
"\110\145\154\157\40\127\157\162\154\144\41"

## \x followed by up to two numbers is interpreted as
## hexadecimal notation for ASCII characters.
(hw1 <- "\x48\x65\x6c\x6f\x20\x57\x6f\x72\x64\x21")

## Mixing octal and hexadecimal in the same string is OK
(hw2 <- "\110\x65\154\x6c\157\20\127\x6f\162\x6c\144\x21")

## \u is also hexadecimal, but supported up to 4 numbers,
## using Unicode specification. In the previous example,
## you can simply replace \x with \u.
(hw3 <- "\u48\u65\u6c\u6f\u20\u57\u6f\u72\u6c\u64\u21")

## The last three are all identical to hw <- "Hello World!"
stopifnot(identical(hw, hw1), identical(hw1, hw2), identical(hw2, hw3))

## Using Unicode makes more sense for non-latin characters.
(nn <- "\u0126\u0119\u1114\u022d\u2001\u03e2\u0954\u0f3f\u13d3\u147b\u203c")

## Mixing \x and \u throws a _parse_ error (which is not catchable!)
## Not run:
"\x48\u65\x6c\x6f\x20\x57\x6f\x72\x64\x21"

## End(Not run)
## --> Error: mixing Unicode and octal/hex escapes .....

## \U works like \u, but supports up to eight numbers.
## So we can replace \u with \U in the previous example.
n2 <- "\U0126\U0119\U1114\U022d\U2001\U03e2\U0954\U0f3f\U13d3\U147b\U203c"
stopifnot(identical(nn, n2))

## Under systems supporting multi-byte locales (and not Windows),
## \U also supports the rarer characters outside the usual 16^4 range.
## See the R language manual,
## https://cran.r-project.org/doc/manuals/r-release/R-lang.html#Literal-constants
## and bug 16098 https://bugs.r-project.org/bugzilla3/show_bug.cgi?id=16098
"\U0d4d7" # On Windows this gives the incorrect value of "\0d4d7"

## nul characters (for terminating strings in C) are not allowed (parse errors)
## Not run:
"foo\0bar" # Error: nul character not allowed (line 1)
"foo\u0000bar" # same error

## End(Not run)

---

### R.Version

<table>
<thead>
<tr>
<th>R.Version</th>
<th>Version Information</th>
</tr>
</thead>
</table>

**Description**

R.Version() provides detailed information about the version of R running.

R.version is a variable (a list) holding this information (and version is a copy of it for S compatibility).
Usage

R.Version()
R.version
R.version.string
version

Details

This gives details of the OS under which R was built, not the one under which it is currently running (for which see Sys.info).

Note that OS names might not be what you expect: for example macOS Mavericks 10.9.4 identifies itself as ‘darwin13.3.0’, Linux usually as ‘linux-gnu’ and Solaris 10 as ‘solaris2.10’.

Value

R.Version returns a list with character-string components

- **platform**: the platform for which R was built. A triplet of the form CPU-VENDOR-OS, as determined by the configure script. E.g, "i686-unknown-linux-gnu" or "i386-pc-mingw32".
- **arch**: the architecture (CPU) R was built on/for.
- **os**: the underlying operating system.
- **system**: CPU and OS, separated by a comma.
- **status**: the status of the version (e.g., “alpha”)
- **major**: the major version number
- **minor**: the minor version number, including the patchlevel
- **year**: the year the version was released
- **month**: the month the version was released
- **day**: the day the version was released
- **svn rev**: the Subversion revision number, which should be either “unknown” or a single number. (A range of numbers or a number with ‘M’ or ‘S’ appended indicates inconsistencies in the sources used to build this version of R.)
- **language**: always “R”.
- **version.string**: a character string concatenating some of the info above, useful for plotting, etc.

R.version and version are lists of class "simple.list" which has a print method.

Note

Do not use R.version$os to test the platform the code is running on: use .Platform$OS.type instead. Slightly different versions of the OS may report different values of R.version$os, as may different versions of R.

R.version.string is a copy of R.version$version.string for simplicity and backwards compatibility.

See Also

sessionInfo which provides additional information; getRversion typically used inside R code, .Platform, Sys.info.
Examples

require(graphics)

R.version$os # to check how lucky you are ...
plot(0) # any plot
mtext(R.version$string, side = 1, line = 4, adj = 1) # a useful bottom-right note

## a good way to detect macOS:
if(grepl("^darwin", R.version$os)) message("running on macOS")

## Short R version string, ("space free", useful in file/directory names;#
## also fine for unreleased versions of R):
shortRversion <- function() {
  rvs <- R.version$string
  if(grepl("devel", (st <- R.version$status)))
    rvs <- sub(paste0(" ",st," "), "-devel_", rvs, fixed=TRUE)
  gsub("[\(\)]", "", gsub(" ", "_", sub(" version ", ":", rvs)))
}
shortRversion()

Description

.Random.seed is an integer vector, containing the random number generator (RNG) state for random number generation in R. It can be saved and restored, but should not be altered by the user.

RNGkind is a more friendly interface to query or set the kind of RNG in use.

RNGversion can be used to set the random generators as they were in an earlier R version (for reproducibility).

set.seed is the recommended way to specify seeds.

Usage

.Random.seed <- c(rng.kind, n1, n2, ...)

RNGkind(kind = NULL, normal.kind = NULL)
RNGversion(vstr)
set.seed(seed, kind = NULL, normal.kind = NULL)

Arguments

kind character or NULL. If kind is a character string, set R’s RNG to the kind desired. Use “default” to return to the R default. See ‘Details’ for the interpretation of NULL.

normal.kind character string or NULL. If it is a character string, set the method of Normal generation. Use “default” to return to the R default. NULL makes no change.

seed a single value, interpreted as an integer, or NULL (see ‘Details’).

vstr a character string containing a version number, e.g., "1.6.2"
rng.kind integer code in 0:k for the above kind.
n1, n2, ... integers. See the details for how many are required (which depends on rng.kind).

Details

The currently available RNG kinds are given below. kind is partially matched to this list. The default is "Mersenne-Twister".

"Wichmann–Hill" The seed, .Random.seed[-1] == r[1:3] is an integer vector of length 3, where each r[i] is in 1:(p[i] - 1), where p is the length 3 vector of primes, p = (30269, 30307, 30323). The Wichmann–Hill generator has a cycle length of \(6.9536 \times 10^{12}\) (= prod(p-1)/4, see Applied Statistics (1984) 33, 123 which corrects the original article).

"Marsaglia-Multicarry": A multiply-with-carry RNG is used, as recommended by George Marsaglia in his post to the mailing list 'sci.stat.math'. It has a period of more than \(2^{60}\) and has passed all tests (according to Marsaglia). The seed is two integers (all values allowed).

"Super-Duper": Marsaglia's famous Super-Duper from the 70's. This is the original version which does not pass the MTUPLE test of the Diehard battery. It has a period of \(\approx 4.6 \times 10^{18}\) for most initial seeds. The seed is two integers (all values allowed for the first seed: the second must be odd).

We use the implementation by Reeds et al (1982–84). The two seeds are the Tausworthe and congruence long integers, respectively. A one-to-one mapping to S's .Random.seed[1:12] is possible but we will not publish one, not least as this generator is not exactly the same as that in recent versions of S-PLUS.

"Mersenne-Twister": From Matsumoto and Nishimura (1998). A twisted GFSR with period \(2^{19937} - 1\) and equidistribution in 623 consecutive dimensions (over the whole period). The 'seed' is a 624-dimensional set of 32-bit integers plus a current position in that set.

"Knuth-TAOCP-2002": A 32-bit integer GFSR using lagged Fibonacci sequences with subtraction. That is, the recurrence used is

\[X_j = (X_{j-100} - X_{j-37}) \mod 2^{30}\]

and the 'seed' is the set of the 100 last numbers (actually recorded as 101 numbers, the last being a cyclic shift of the buffer). The period is around \(2^{129}\).

"Knuth-TAOCP": An earlier version from Knuth (1997). The 2002 version was not backwards compatible with the earlier version: the initialization of the GFSR from the seed was altered. R did not allow you to choose consecutive seeds, the reported 'weakness'; and already scrambled the seeds. Initialization of this generator is done in interpreted R code and so takes a short but noticeable time.

"L’Ecuyer-CMRG": A ‘combined multiple-recursive generator’ from L’Ecuyer (1999), each element of which is a feedback multiplicative generator with three integer elements: thus the seed is a (signed) integer vector of length 6. The period is around \(2^{191}\).

The 6 elements of the seed are internally regarded as 32-bit unsigned integers. Neither the first three nor the last three should be all zero, and they are limited to less than 4294967087 and 4294944443 respectively.

This is not particularly interesting of itself, but provides the basis for the multiple streams used in package parallel.

"user-supplied": Use a user-supplied generator. See Random.user for details.
normal.kind can be "Kinderman-Ramage", "Buggy Kinderman-Ramage" (not for set.seed), "Ahrens-Dieter", "Box-Muller", "Inversion" (the default), or "user-supplied". (For inversion, see the reference in qnorm.) The Kinderman-Ramage generator used in versions prior to 1.7.0 (now called "Buggy") had several approximation errors and should only be used for reproduction of old results. The "Box-Muller" generator is stateful as pairs of normals are generated and returned sequentially. The state is reset whenever it is selected (even if it is the current normal generator) and when kind is changed.

set.seed uses a single integer argument to set as many seeds as are required. It is intended as a simple way to get quite different seeds by specifying small integer arguments, and also as a way to get valid seed sets for the more complicated methods (especially "Mersenne-Twister" and "Knuth-TAOCP"). There is no guarantee that different values of seed will seed the RNG differently, although any exceptions would be extremely rare. If called with seed = NULL it re-initializes (see 'Note') as if no seed had yet been set.

The use of kind = NULL or normal.kind = NULL in RNGkind or set.seed selects the currently-used generator (including that used in the previous session if the workspace has been restored): if no generator has been used it selects "default".

Value

.Random.seed is an integer vector whose first element codes the kind of RNG and normal generator. The lowest two decimal digits are in 0:(k-1) where k is the number of available RNGs. The hundreds represent the type of normal generator (starting at 0).

In the underlying C, .Random.seed[-1] is unsigned; therefore in R .Random.seed[-1] can be negative, due to the representation of an unsigned integer by a signed integer.

RNGkind returns a two-element character vector of the RNG and normal kinds selected before the call, invisibly if either argument is not NULL. A type starts a session as the default, and is selected either by a call to RNGkind or by setting .Random.seed in the workspace.

RNGversion returns the same information as RNGkind about the defaults in a specific R version.

set.seed returns NULL, invisibly.

Note

Initially, there is no seed; a new one is created from the current time and the process ID when one is required. Hence different sessions will give different simulation results, by default. However, the seed might be restored from a previous session if a previously saved workspace is restored.

.Random.seed saves the seed set for the uniform random-number generator, at least for the system generators. It does not necessarily save the state of other generators, and in particular does not save the state of the Box–Muller normal generator. If you want to reproduce work later, call set.seed (preferably with explicit values for kind and normal.kind) rather than set .Random.seed.

The object .Random.seed is only looked for in the user’s workspace.

Do not rely on randomness of low-order bits from RNGs. Most of the supplied uniform generators return 32-bit integer values that are converted to doubles, so they take at most $2^{32}$ distinct values and long runs will return duplicated values (Wichmann-Hill is the exception, and all give at least 30 varying bits.)

Examples

```r
require(stats)

## the default random seed is 626 integers, so only print a few
runif(1); .Random.seed[1:6]; runif(1); .Random.seed[1:6]

## If there is no seed, a "random" new one is created:
rm(.Random.seed); runif(1); .Random.seed[1:6]

ok <- RNGkind()
RNGkind("Wich") # (partial string matching on 'kind')

## This shows how 'runif(.)' works for Wichmann-Hill,
```
## using only R functions:

```r
p.WH <- c(30269, 30307, 30323)
a.WH <- c(171, 172, 170)
next.WHseed <- function(i.seed = .Random.seed[-1])
  { (a.WH * i.seed) %% p.WH }
my.runif1 <- function(i.seed = .Random.seed)
  { ns <- next.WHseed(i.seed[-1]); sum(ns / p.WH) %% 1 }
rs <- .Random.seed
(WHs <- next.WHseed(rs[-1]))

(u <- runif(1))
stopifnot(
  next.WHseed(rs[-1]) == .Random.seed[-1],
  all.equal(u, my.runif1(rs))
)
```

## ----

```r
.RANDOM.SEED
RNGkind("Super") # matches "Super-Duper"
RNGkind()
.RANDOM.SEED # new, corresponding to Super-Duper

## Reset:
RNGkind(ok[1])
```

```r
## ----

sum(duplicated(runif(1e6))) # around 110 for default generator
## and we would expect about almost sure duplicates beyond about
qbirthday(1 - 1e-6, classes = 2e9) # 235,000
```

---

Random.user  

User-supplied Random Number Generation

### Description

Function `RNGkind` allows user-coded uniform and normal random number generators to be supplied. The details are given here.

### Details

A user-specified uniform RNG is called from entry points in dynamically-loaded compiled code. The user must supply the entry point `user_unif_rand`, which takes no arguments and returns a pointer to a double. The example below will show the general pattern. The generator should have at least 25 bits of precision.

Optionally, the user can supply the entry point `user_unif_init`, which is called with an unsigned int argument when `RNGkind` (or `set.seed`) is called, and is intended to be used to initialize the user’s RNG code. The argument is intended to be used to set the ‘seeds’; it is the seed argument to `set.seed` or an essentially random seed if `RNGkind` is called.

If only these functions are supplied, no information about the generator’s state is recorded in `.Random.seed`. Optionally, functions `user_unif_nseed` and `user_unif_seedloc` can be supplied which are called with no arguments and should return pointers to the number of seeds and to an integer (`specifically, ‘Int32’`) array of seeds. Calls to `GetRNGstate` and `PutRNGstate` will then copy this array to and from `.Random.seed`. 
A user-specified normal RNG is specified by a single entry point `user_norm_rand`, which takes no arguments and returns a pointer to a double.

**Warning**

As with all compiled code, mis-specifying these functions can crash R. Do include the `R_ext/Random.h` header file for type checking.

**Examples**

```c
## Not run:
## Marsaglia's congruential PRNG
#include <R_ext/Random.h>

static Int32 seed;
static double res;
static int nseed = 1;

double * user_unif_rand()
{
    seed = 69069 * seed + 1;
    res = seed * 2.32830643653869e-10;
    return &res;
}

void user_unif_init(Int32 seed_in) { seed = seed_in; }
int * user_unif_nseed() { return &nseed; }
int * user_unif_seedloc() { return (int *) &seed; }

/* ratio-of-uniforms for normal */
#include <math.h>
static double x;

double * user_norm_rand()
{
    double u, v, z;
    do {
        u = unif_rand();
        v = 0.857764 * (2. * unif_rand() - 1);
        x = v/u; z = 0.25 * x * x;
        if (z < 1. - u) break;
        if (z > 0.259/u + 0.35) continue;
    } while (z > -log(u));
    return &x;
}

## Use under Unix:
R CMD SHLIB urand.c
R
> dyn.load("urand.so")
> RNGkind("user")
> runif(10)
> .Random.seed
> RNGkind(, "user")
> rmnorm(10)
> RNGkind()
[1] "user-supplied"  "user-supplied"
```
range

Range of Values

Description
range returns a vector containing the minimum and maximum of all the given arguments.

Usage
range(..., na.rm = FALSE)

## Default S3 method:
range(..., na.rm = FALSE, finite = FALSE)

Arguments
...
any numeric or character objects.
na.rm
logical, indicating if NA’s should be omitted.
finite
logical, indicating if all non-finite elements should be omitted.

Details
range is a generic function: methods can be defined for it directly or via the Summary group generic. For this to work properly, the arguments ... should be unnamed, and dispatch is on the first argument.

If na.rm is FALSE, NA and NaN values in any of the arguments will cause NA values to be returned, otherwise NA values are ignored.

If finite is TRUE, the minimum and maximum of all finite values is computed, i.e., finite = TRUE includes na.rm = TRUE.

A special situation occurs when there is no (after omission of NAs) nonempty argument left, see min.

S4 methods
This is part of the S4 Summary group generic. Methods for it must use the signature x, ..., na.rm.

References

See Also
min, max.
The extendrange() utility in package grDevices.
Examples

(r.x <- range(stats::rnorm(100)))

diff(r.x) # the SAMPLE range

x <- c(NA, 1:3, -1:1/0); x
range(x)
range(x, na.rm = TRUE)
range(x, finite = TRUE)

rank

Sample Ranks

Description

Returns the sample ranks of the values in a vector. Ties (i.e., equal values) and missing values can be handled in several ways.

Usage

rank(x, na.last = TRUE,
ties.method = c("average", "first", "last", "random", "max", "min"))

Arguments

x a numeric, complex, character or logical vector.
na.last for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.
ties.method a character string specifying how ties are treated, see ‘Details’; can be abbreviated.

Details

If all components are different (and no NAs), the ranks are well defined, with values in seq_along(x). With some values equal (called ‘ties’), the argument ties.method determines the result at the corresponding indices. The “first” method results in a permutation with increasing values at each index set of ties, and analogously "last" with decreasing values. The "random" method puts these in random order whereas the default, "average", replaces them by their mean, and "max" and "min" replaces them by their maximum and minimum respectively, the latter being the typical sports ranking.

NA values are never considered to be equal: for na.last = TRUE and na.last = FALSE they are given distinct ranks in the order in which they occur in x.

NB: rank is not itself generic but xtfrm is, and rank(xtfrm(x), ....) will have the desired result if there is a xtfrm method. Otherwise, rank will make use of ==, >, is.na and extraction methods for classed objects, possibly rather slowly.

Value

A numeric vector of the same length as x with names copied from x (unless na.last = NA, when missing values are removed). The vector is of integer type unless x is a long vector or ties.method = "average" when it is of double type (whether or not there are any ties).
References

See Also

`order` and `sort::xtfrm`, see above.

Examples

```r
(r1 <- rank(x1 <- c(3, 1, 4, 15, 92)))
x2 <- c(3, 1, 4, 1, 5, 9, 2, 6, 5, 3, 5)
names(x2) <- letters[1:11]
(r2 <- rank(x2)) # ties are averaged

## rank() is "idempotent": rank(rank(x)) == rank(x):
stopifnot(rank(r1) == r1, rank(r2) == r2)

## ranks without averaging
rank(x2, ties.method= "first") # first occurrence wins
rank(x2, ties.method= "last") # last occurrence wins
rank(x2, ties.method= "random") # ties broken at random
rank(x2, ties.method= "random") # and again

## keep ties ties, no average
(rma <- rank(x2, ties.method= "max")) # as used classically
(rmi <- rank(x2, ties.method= "min")) # as in Sports
stopifnot(rma + rmi == round(r2 + r2))

## Comparing all tie.methods:
tMeth <- eval(formals(rank)$ties.method)
rx2 <- sapply(tMeth, function(M) rank(x2, ties.method=M))
cbind(x2, rx2)

## ties.method's does not matter w/o ties:
x <- sample(47)
rx <- sapply(tMeth, function(MM) rank(x, ties.method=MM))
stopifnot(all(rx[,1] == rx))
```

rapply

*Recursively Apply a Function to a List*

Description

`rapply` is a recursive version of `lapply`.

Usage

`rapply(object, f, classes = "ANY", deflt = NULL, how = c("unlist", "replace", "list"), ...)"
Arguments

object  A list.

f  A function of a single argument.

classes  A character vector of class names, or "ANY" to match any class.

deflt  The default result (not used if how = "replace").

how  A character string partially matching the three possibilities given: see ‘Details’.

...  additional arguments passed to the call to f.

Details

This function has two basic modes. If how = "replace", each element of the list which is not itself a list and has a class included in classes is replaced by the result of applying f to the element.

If the mode is how = "list" or how = "unlist", the list is copied, all non-list elements which have a class included in classes are replaced by the result of applying f to the element and all others are replaced by deflt. Finally, if how = "unlist", unlist(recursive = TRUE) is called on the result.

The semantics differ in detail from lapply: in particular the arguments are evaluated before calling the C code.

Value

If how = "unlist", a vector, otherwise a list of similar structure to object.

References

(rapply is only described briefly there.)

See Also

lapply, dendrapply.

Examples

X <- list(list(a = pi, b = list(c = 1:1)), d = "a test")
rapply(X, function(x) x, how = "replace")
rapply(X, sqrt, classes = "numeric", how = "replace")
rapply(X, nchar, classes = "character", deflt = as.integer(NA), how = "list")
rapply(X, nchar, classes = "character", deflt = as.integer(NA), how = "unlist")
rapply(X, log, classes = "numeric", how = "replace", base = 2)
Description

Creates or tests for objects of type "raw".

Usage

```r
raw(length = 0)
as.raw(x)
is.raw(x)
```

Arguments

- `length` desired length.
- `x` object to be coerced.

Details

The raw type is intended to hold raw bytes. It is possible to extract subsequences of bytes, and to replace elements (but only by elements of a raw vector). The relational operators (see Comparison, using the numerical order of the byte representation) work, as do the logical operators (see Logic) with a bitwise interpretation.

A raw vector is printed with each byte separately represented as a pair of hex digits. If you want to see a character representation (with escape sequences for non-printing characters) use `rawToChar`.

Coercion to raw treats the input values as representing small (decimal) integers, so the input is first coerced to integer, and then values which are outside the range [0 . . . 255] or are `NA` are set to 0 (the nul byte).

`as.raw` and `is.raw` are primitive functions.

Value

`raw` creates a raw vector of the specified length. Each element of the vector is equal to 0. Raw vectors are used to store fixed-length sequences of bytes.

`as.raw` attempts to coerce its argument to be of raw type. The (elementwise) answer will be 0 unless the coercion succeeds (or if the original value successfully coerces to 0).

`is.raw` returns true if and only if `typeof(x) == "raw"`.

See Also

`charToRaw`, `rawShift`, etc.

`&` for bitwise operations on raw vectors.
rawConnection

Examples

xx <- raw(2)
xx[1] <- as.raw(40)  # NB, not just 40.
xx[2] <- charToRaw("A")
xx ## 28 41  -- raw prints hexadecimals
dput(xx) ## as.raw(c(0x28, 0x41))
as.integer(xx) ## 40 65

x <- "A test string"
(y <- charToRaw(x))
is.vector(y) # TRUE
rawToChar(y)
is.raw(x)
is.raw(y)
stopifnot(charToRaw("\xa3") == as.raw(0xa3))

isASCII <- function(txt) all(charToRaw(txt) <= as.raw(127))
isASCII(x) # true
isASCII("\xa325.63") # false (in Latin-1, this is an amount in UK pounds)

Description

Input and output raw connections.

Usage

rawConnection(object, open = "r")

rawConnectionValue(con)

Arguments

object character or raw vector. A description of the connection. For an input this is an R raw vector object, and for an output connection the name for the connection.

open character. Any of the standard connection open modes.

con An output raw connection.

Details

An input raw connection is opened and the raw vector is copied at the time the connection object is created, and close destroys the copy.

An output raw connection is opened and creates an R raw vector internally. The raw vector can be retrieved via rawConnectionValue.

If a connection is open for both input and output the initial raw vector supplied is copied when the connections is open.
For `rawConnection`, a connection object of class "rawConnection" which inherits from class "connection".

For `rawConnectionValue`, a raw vector.

Note

As output raw connections keep the internal raw vector up to date call-by-call, they are relatively expensive to use (although over-allocation is used), and it may be better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

See Also

`connections`, `showConnections`.

Examples

```r
zz <- rawConnection(raw(0), "r") # start with empty raw vector
writeBin(LETTERS, zz)
seek(zz, 0)
readLines(zz) # raw vector has embedded nuls
seek(zz, 0)
writeBin(letters[1:3], zz)
rawConnectionValue(zz)
close(zz)
```

---

**rawConversion Convert to or from Raw Vectors**

Description

Conversion and manipulation of objects of type "raw".

Usage

```r
charToRaw(x)
rawToChar(x, multiple = FALSE)
rawShift(x, n)
rawToBits(x)
intToBits(x)
packBits(x, type = c("raw", "integer"))
```
Arguments

x object to be converted or shifted.

multiple logical: should the conversion be to a single character string or multiple individual characters?

n the number of bits to shift. Positive numbers shift right and negative numbers shift left: allowed values are \(-8 \ldots 8\).

type the result type, partially matched.

Details

packBits accepts raw, integer or logical inputs, the last two without any NAs. Note that 'bytes' are not necessarily the same as characters, e.g. in UTF-8 locales.

Value

charToRaw converts a length-one character string to raw bytes. It does so without taking into account any declared encoding (see Encoding).

rawToChar converts raw bytes either to a single character string or a character vector of single bytes (with '"' for \0). (Note that a single character string could contain embedded nuls; only trailing nulls are allowed and will be removed.) In either case it is possible to create a result which is invalid in a multibyte locale, e.g. one using UTF-8. Long vectors are allowed if multiple is true.

rawShift\(x, n\) shift the bits in \(x\) by \(n\) positions to the right, see the argument \(n\), above.

rawToBits returns a raw vector of 8 times the length of a raw vector with entries 0 or 1. intToBits returns a raw vector of 32 times the length of an integer vector with entries 0 or 1. (Non-integral numeric values are truncated to integers.) In both cases the unpacking is least-significant bit first.

packBits packs its input (using only the lowest bit for raw or integer vectors) least-significant bit first to a raw or integer vector.

Examples

x <- "A test string"
(y <- charToRaw(x))
is.vector(y) # TRUE

rawToChar(y)
rawToChar(y, multiple = TRUE)
(xx <- c(y, charToRaw("&"), charToRaw("more")))
rawToChar(xx)

rawShift(y, 1)
rawShift(y, -2)

rawToBits(y)

showBits <- function(r) stats::symnum(as.logical(rawToBits(r)))

z <- as.raw(5)
z ; showBits(z)
showBits(rawShift(z, 1)) # shift to right
showBits(rawShift(z, 2))
showBits(z)
showBits(rawShift(z, -1)) # shift to left
showBits(rawShift(z, -2)) # ..
showBits(rawShift(z, -3)) # shifted off entirely

RdUtils

Utilities for Processing Rd Files

Description

Utilities for converting files in R documentation (Rd) format to other formats or create indices from
them, and for converting documentation in other formats to Rd format.

Usage

R CMD Rdconv [options] file
R CMD Rd2pdf [options] files

Arguments

file the path to a file to be processed.
files a list of file names specifying the R documentation sources to use, by either
giving the paths to the files, or the path to a directory with the sources of a
package.
options further options to control the processing, or for obtaining information about usage
and version of the utility.

Details

R CMD Rdconv converts Rd format to plain text, HTML or LaTeX formats: it can also extract the
examples.

R CMD Rd2pdf is the user-level program for producing PDF output from Rd sources. It will make use
of the environment variables R_PAPERSIZE (set by R CMD, with a default set when R was installed:
values for R_PAPERSIZE are a4, letter, legal and executive) and R_PDFVIEWER (the PDF pre-
viewer). Also, RD2PDF_INPUTENC can be set to inputenx to make use of the LaTeX package of that
name rather than inputenc: this might be needed for better support of the UTF-8 encoding.

R CMD Rd2pdf calls tools::texi2pdf to produce its PDF file: see its help for the possibilities for
the texi2dvi command which that function uses (and which can be overridden by setting environ-
ment variable R_TEXI2DVI_CMD).

Use R CMD foo --help to obtain usage information on utility foo.

See Also

The chapter “Processing Rd format” in the “Writing R Extensions” manual.
**readBin**

Transfer Binary Data To and From Connections

**Description**

Read binary data from or write binary data to a connection or raw vector.

**Usage**

```r
readBin(con, what, n = 1L, size = NA_integer_, signed = TRUE, endian = .Platform$_endian)
writeBin(object, con, size = NA_integer_, endian = .Platform$_endian, useBytes = FALSE)
```

**Arguments**

- **con**: A connection object or a character string naming a file or a raw vector.
- **what**: Either an object whose mode will give the mode of the vector to be read, or a character vector of length one describing the mode: one of "numeric", "double", "integer", "int", "logical", "complex", "character", "raw".
- **n**: integer. The (maximal) number of records to be read. You can use an overestimate here, but not too large as storage is reserved for n items.
- **size**: integer. The number of bytes per element in the byte stream. The default, NA_integer_, uses the natural size. Size changing is not supported for raw and complex vectors.
- **signed**: logical. Only used for integers of sizes 1 and 2, when it determines if the quantity on file should be regarded as a signed or unsigned integer.
- **endian**: The endian-ness ("big" or "little") of the target system for the file. Using "swap" will force swapping endian-ness.
- **object**: An R object to be written to the connection.
- **useBytes**: See writeLines.

**Details**

These functions are intended to be used with binary-mode connections. If con is a character string, the functions call file to obtain a binary-mode file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If readBin is called with con a raw vector, the data in the vector is used as input. If writeBin is called with con a raw vector, it is just an indication that a raw vector should be returned.

If size is specified and not the natural size of the object, each element of the vector is coerced to an appropriate type before being written or as it is read. Possible sizes are 1, 2, 4 and possibly 8 for integer or logical vectors, and 4, 8 and possibly 12/16 for numeric vectors. (Note that coercion occurs as signed types except if signed = FALSE when reading integers of sizes 1 and 2.) Changing
sizes is unlikely to preserve NAs, and the extended precision sizes are unlikely to be portable across platforms.

`readBin` and `writeBin` read and write C-style zero-terminated character strings. Input strings are limited to 10000 characters. `readChar` and `writeChar` can be used to read and write fixed-length strings. No check is made that the string is valid in the current locale’s encoding.

Handling R’s missing and special (Inf, -Inf and NaN) values is discussed in the ‘R Data Import/Export’ manual.

Only \(2^{31} - 1\) bytes can be written in a single call (and that is the maximum capacity of a raw vector on 32-bit platforms).

‘Endian-ness’ is relevant for size > 1, and should always be set for portable code (the default is only appropriate when writing and then reading files on the same platform).

**Value**

For `readBin`, a vector of appropriate mode and length the number of items read (which might be less than `n`).

For `writeBin`, a raw vector (if `con` is a raw vector) or invisibly `NULL`.

**Note**

Integer read/writes of size 8 will be available if either C type `long` is of size 8 bytes or C type `long` long exists and is of size 8 bytes.

Real read/writes of size `sizeof(long double)` (usually 12 or 16 bytes) will be available only if that type is available and different from double.

If `readBin(what = character())` is used incorrectly on a file which does not contain C-style character strings, warnings (usually many) are given. From a file or connection, the input will be broken into pieces of length 10000 with any final part being discarded.

Using these functions on a text-mode connection may work but should not be mixed with text-mode access to the connection, especially if the connection was opened with an encoding argument.

**See Also**

The ‘R Data Import/Export’ manual.

`readChar` to read/write fixed-length strings.

`connections, readLines, writeLines`

`.Machine` for the sizes of `long`, `long long` and `long double`.

**Examples**

```r
zz <- file("testbin", "wb")
writeBin(1:10, zz)
writeBin(pi, zz, endian = "swap")
writeBin(pi, zz, size = 4)
writeBin(pi*2, zz, size = 4, endian = "swap")
writeBin(pi+3i, zz)
writeBin("A test of a connection", zz)
z <- paste("A very long string", 1:100, collapse = " + ")
writeBin(z, zz)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  writeBin(as.integer(5^(1:10)), zz, size = 8)
if((s <- .Machine$sizeof.longdouble) > 8)
```
readChar

Transfer Character Strings To and From Connections

Description

Transfer character strings to and from connections, without assuming they are null-terminated on
the connection.

Usage

readChar(con, nchars, useBytes = FALSE)
writeChar(object, con, nchars = nchar(object, type = "chars"),
          eos = "", useBytes = FALSE)

Arguments

- **con**: A connection object, or a character string naming a file, or a raw vector.
- **nchars**: integer vector, giving the lengths in characters of (unterminated) character strings to be read or written. Elements must be >= 0 and not NA.
- **useBytes**: logical: For readChar, should nchars be regarded as a number of bytes not characters in a multi-byte locale? For writeChar, see writeLines.
- **object**: A character vector to be written to the connection, at least as long as nchars.
- **eos**: ‘end of string’: character string. The terminator to be written after each string, followed by an ASCII nul; use NULL for no terminator at all.

Details

These functions complement readBin and writeBin which read and write C-style zero-terminated character strings. They are for strings of known length, and can optionally write an end-of-string mark. They are intended only for character strings valid in the current locale.

These functions are intended to be used with binary-mode connections. If con is a character string, the functions call file to obtain a binary-mode file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If readChar is called with con a raw vector, the data in the vector is used as input. If writeChar is called with con a raw vector, it is just an indication that a raw vector should be returned.

Character strings containing ASCII nul(s) will be read correctly by readChar but truncated at the first nul with a warning.

If the character length requested for readChar is longer than the data available on the connection, what is available is returned. For writeChar if too many characters are requested the output is zero-padded, with a warning.

Missing strings are written as NA.

Value

For readChar, a character vector of length the number of items read (which might be less than length(nchars)).
For writeChar, a raw vector (if con is a raw vector) or invisibly NULL.

Note

Earlier versions of R allowed embedded nul bytes within character strings, but not R >= 2.8.0. readChar was commonly used to read fixed-size zero-padded byte fields for which readBin was unsuitable. readChar can still be used for such fields if there are no embedded nuls: otherwise readBin(what = "raw") provides an alternative.

nchars will be interpreted in bytes not characters in a non-UTF-8 multi-byte locale, with a warning. There is little validity checking of UTF-8 reads.
Using these functions on a text-mode connection may work but should not be mixed with text-mode access to the connection, especially if the connection was opened with an encoding argument.

See Also

The ‘R Data Import/Export’ manual.

connections, readLines, writeLines, readBin

Examples

```r
## test fixed-length strings
zz <- file("testchar", "wb")
x <- c("a", "this will be truncated", "abc")
nc <- c(3, 10, 3)
writeChar(x, zz, nc, eos = NULL)
writeChar(x, zz, eos = "\r\n")
close(zz)

zz <- file("testchar", "rb")
readChar(zz, nc)
readChar(zz, nchar(x)+3) # need to read the terminator explicitly
close(zz)
unlink("testchar")
```

**readline**

*Read a Line from the Terminal*

**Description**

`readline` reads a line from the terminal (in interactive use).

**Usage**

`readline(prompt = "")`

**Arguments**

- `prompt` the string printed when prompting the user for input. Should usually end with a space " ".

**Details**

The prompt string will be truncated to a maximum allowed length, normally 256 chars (but can be changed in the source code).

This can only be used in an interactive session.

**Value**

A character vector of length one. Both leading and trailing spaces and tabs are stripped from the result.

In non-interactive use the result is as if the response was RETURN and the value is " ".
See Also

readLines for reading text lines from connections, including files.

Examples

fun <- function() {
  ANSWER <- readline("Are you a satisfied R user? ")
  ## a better version would check the answer less cursorily, and
  ## perhaps re-prompt
  if (substr(ANSWER, 1, 1) == "n")
    cat("This is impossible. YOU LIED!\n")
  else
    cat("I knew it.\n")
  }
  if(interactive()) fun()

readLines

Read Text Lines from a Connection

Description

Read some or all text lines from a connection.

Usage

readLines(con = stdin(), n = -1L, ok = TRUE, warn = TRUE,
          encoding = "unknown", skipNul = FALSE)

Arguments

con   a connection object or a character string.
n     integer. The (maximal) number of lines to read. Negative values indicate that
       one should read up to the end of input on the connection.
ok    logical. Is it OK to reach the end of the connection before \( n > 0 \) lines are read? If not, an error will be generated.
warn  logical. Warn if a text file is missing a final EOL or if there are embedded nuls
       in the file.
encoding encoding to be assumed for input strings. It is used to mark character strings
       as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the
       latter, specify the encoding as part of the connection con or via
       options(encoding=); see the examples.
skipNul logical: should nuls be skipped?

Details

If the con is a character string, the function calls file to obtain a file connection which is opened
for the duration of the function call. This can be a compressed file.

If the connection is open it is read from its current position. If it is not open, it is opened in "rt"
mode for the duration of the call and then closed (but not destroyed; one must call close to do that).
readLines

If the final line is incomplete (no final EOL marker) the behaviour depends on whether the connection is blocking or not. For a non-blocking text-mode connection the incomplete line is pushed back, silently. For all other connections the line will be accepted, with a warning.

Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line.

Embedded nuls in the input stream will terminate the line currently being read, with a warning (unless `skipNul = TRUE` or `warn = FALSE`).

If `con` is a not-already-open connection with a non-default encoding argument, the text is converted to UTF-8 and declared as such (and the encoding argument to `readLines` is ignored). See the examples.

Value

A character vector of length the number of lines read.

The elements of the result have a declared encoding if `encoding` is "latin1" or "UTF-8",

Note

The default connection, `stdin`, may be different from `con = "stdin"`: see `file`.

See Also

`connections`, `writeLines`, `readBin`, `scan`

Examples

cat("TITLE extra line", "2 3 5 7", ",", "11 13 17", file = "ex.data", sep = "\n")
readLines("ex.data", n = -1)
unlink("ex.data") # tidy up

## difference in blocking

```
cat("123\nabc", file = "test1")
readLines("test1") # line with a warning
```

```
con <- file("test1", "r", blocking = FALSE)
readLines(con) # empty
cat(" def\n", file = "test1", append = TRUE)
readLines(con) # gets both
close(con)
```

```
unlink("test1") # tidy up
```

## Not run:
# read a 'Windows Unicode' file
A <- readLines(con <- file("Unicode.txt", encoding = "UCS-2LE"))
close(con)
unique(Encoding(A)) # will most likely be UTF-8
```

## End(Not run)
Description

Functions to write a single R object to a file, and to restore it.

Usage

```r
saveRDS(object, file = "", ascii = FALSE, version = NULL,
        compress = TRUE, refhook = NULL)

readRDS(file, refhook = NULL)
```

Arguments

- **object**: R object to serialize.
- **file**: a connection or the name of the file where the R object is saved to or read from.
- **ascii**: a logical. If TRUE or NA, an ASCII representation is written; otherwise (default), a binary one is used. See the comments in the help for `save`.
- **version**: the workspace format version to use. NULL specifies the current default version (2). Versions prior to 2 are not supported, so this will only be relevant when there are later versions.
- **compress**: a logical specifying whether saving to a named file is to use "gzip" compression, or one of "gzip", "bzip2" or "xz" to indicate the type of compression to be used. Ignored if file is a connection.
- **refhook**: a hook function for handling reference objects.

Details

These functions provide the means to save a single R object to a connection (typically a file) and to restore the object, quite possibly under a different name. This differs from `save` and `load`, which save and restore one or more named objects into an environment. They are widely used by R itself, for example to store metadata for a package and to store the `help.search` databases: the ".rds" file extension is most often used.

Functions `serialize` and `unserialize` provide a slightly lower-level interface to serialization: objects serialized to a connection by `serialize` can be read back by `readRDS` and conversely.

All of these interfaces use the same serialization format, which has been used since R 1.4.0 (but extended from time to time as new object types have been added to R). However, `save` writes a single line header (typically "RDXs\n") before the serialization of a single object (a pairlist of all the objects to be saved).

Compression is handled by the connection opened when `file` is a file name, so is only possible when `file` is a connection if handled by the connection. So e.g. `url` connections will need to be wrapped in a call to `gzcon`.

If a connection is supplied it will be opened (in binary mode) for the duration of the function if not already open: if it is already open it must be in binary mode for `saveRDS(ascii = FALSE)` or to read non-ASCII saves.
Value
For readRDS, an R object.
For saveRDS, NULL invisibly.

See Also
serialize, save and load.
The 'R Internals' manual for details of the format used.

Examples
## save a single object to file
saveRDS(women, "women.rds")
## restore it under a different name
women2 <- readRDS("women.rds")
identical(women, women2)
## or examine the object via a connection, which will be opened as needed.
con <- gzfile("women.rds")
readRDS(con)
close(con)

## Less convenient ways to restore the object
## which demonstrate compatibility with unserialize()
con <- gzfile("women.rds", "rb")
identical(unserialize(con), women)
close(con)
con <- gzfile("women.rds", "rb")
wm <- readBin(con, "raw", n = 1e4) # size is a guess
close(con)
identical(unserialize(wm), women)

## Format compatibility with serialize():
con <- file("women2", "w")
serialize(women, con) # ASCII, uncompressed
close(con)
identical(women, readRDS("women2"))
con <- bzfile("women3", "w")
serialize(women, con) # binary, bzip2-compressed
close(con)
identical(women, readRDS("women2"))
Recall

Arguments

path  A length-one character vector giving the path to the file. Tilde-expansion is performed where supported.

Value

Scalar logical indicating if the file was read successfully. Returned invisibly. If the file cannot be opened for reading, a warning is given.

See Also

Startup for the file format.

Examples

## Not run:
## re-read a startup file (or read it in a vanilla session)
readRenviron("~/.Renviron")
## End(Not run)

Recall

Recursive Calling

Description

Recall is used as a placeholder for the name of the function in which it is called. It allows the definition of recursive functions which still work after being renamed, see example below.

Usage

Recall(...)

Arguments

...  all the arguments to be passed.

Note

Recall will not work correctly when passed as a function argument, e.g. to the apply family of functions.

See Also

do.call and call.

local for another way to write anonymous recursive functions.
Examples

```r
## A trivial (but inefficient!) example:
fib <- function(n)
  if(n<=2) { if(n>=0) 1 else 0 } else Recall(n-1) + Recall(n-2)
fibonacci <- fib; rm(fib)
## renaming wouldn't work without Recall
fibonacci(10) # 55
```
See Also
gc and Memory for garbage collection and memory management.

Examples

```r
f <- function(e) print("cleaning....")
g <- function(x){ e <- environment(); reg.finalizer(e, f) }
g()
invisible(gc()) # trigger cleanup
```

Description

This help page documents the regular expression patterns supported by `grep` and related functions `grepl`, `regexpr`, `gregexpr`, `sub` and `gsub`, as well as by `strsplit`.

Details

A ‘regular expression’ is a pattern that describes a set of strings. Two types of regular expressions are used in R, extended regular expressions (the default) and Perl-like regular expressions used by `perl = TRUE`. There is also `fixed = TRUE` which can be considered to use a literal regular expression.

Other functions which use regular expressions (often via the use of `grep`) include `apropos`, `browseEnv`, `help.search`, `list.files` and `ls`. These will all use extended regular expressions.

Patterns are described here as they would be printed by `cat`: (do remember that backslashes need to be doubled when entering R character strings, e.g. from the keyboard).

Long regular expression patterns may or may not be accepted: the POSIX standard only requires up to 256 bytes.

Extended Regular Expressions

This section covers the regular expressions allowed in the default mode of `grep`, `grep`, `regexpr`, `gregexpr`, `sub`, `gsub`, `regexec` and `strsplit`. They use an implementation of the POSIX 1003.2 standard: that allows some scope for interpretation and the interpretations here are those currently used by R. The implementation supports some extensions to the standard.

Regular expressions are constructed analogously to arithmetic expressions, by using various operators to combine smaller expressions. The whole expression matches zero or more characters (read ‘character’ as ‘byte’ if `useBytes = TRUE`).

The fundamental building blocks are the regular expressions that match a single character. Most characters, including all letters and digits, are regular expressions that match themselves. Any metacharacter with special meaning may be quoted by preceding it with a backslash. The metacharacters in extended regular expressions are ‘. \ | ( ) [ { ^ $ * + ?’, but note that whether these have a special meaning depends on the context.

Escaping non-metacharacters with a backslash is implementation-dependent. The current implementation interprets ‘\a’ as ‘BEL’, ‘\e’ as ‘ESC’, ‘\f’ as ‘FF’, ‘\n’ as ‘LF’, ‘\r’ as ‘CR’ and ‘\t’ as ‘TAB’. (Note that these will be interpreted by R’s parser in literal character strings.)
A character class is a list of characters enclosed between `['` and `']` which matches any single character in that list; unless the first character of the list is the caret `^`, when it matches any character not in the list. For example, the regular expression `['0123456789']` matches any single digit, and `['abc']` matches anything except the characters `a`, `b` or `c`. A range of characters may be specified by giving the first and last characters, separated by a hyphen. (Because their interpretation is locale- and implementation-dependent, character ranges are best avoided.) The only portable way to specify all ASCII letters is to list them all as the character class `['ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz']`. (The current implementation uses numerical order of the encoding.)

Certain named classes of characters are predefined. Their interpretation depends on the locale (see locales); the interpretation below is that of the POSIX locale.

`[[:blank:] ]` Blank characters: space and tab, and possibly other locale-dependent characters such as non-breaking space.

`[[:cntrl:] ]` Control characters. In ASCII, these characters have octal codes 000 through 037, and 177 (DEL). In another character set, these are the equivalent characters, if any.

`[[:digit:] ]` Digits: `0 1 2 3 4 5 6 7 8 9`.

`[[:lower:] ]` Lower-case letters in the current locale.

`[[:print:] ]` Printable characters: `['[:alnum:] ], ['[:punct:] ]` and space.

`[[:punct:] ]` Punctuation characters:

`[[:space:] ]` Space characters: tab, newline, vertical tab, form feed, carriage return, space and possibly other locale-dependent characters.

`[[:upper:] ]` Upper-case letters in the current locale.

`[[:xdigit:] ]` Hexadecimal digits:

A regular expression may be followed by one of several repetition quantifiers:

`?` The preceding item is optional and will be matched at most once.
\* The preceding item will be matched zero or more times.
\+ The preceding item will be matched one or more times.
\{n\} The preceding item is matched exactly \( n \) times.
\{(n,\)} The preceding item is matched \( n \) or more times.
\{(n,m}\) The preceding item is matched at least \( n \) times, but not more than \( m \) times.

By default repetition is greedy, so the maximal possible number of repeats is used. This can be changed to ‘minimal’ by appending ? to the quantifier. (There are further quantifiers that allow approximate matching: see the TRE documentation.)

Regular expressions may be concatenated; the resulting regular expression matches any string formed by concatenating the substrings that match the concatenated subexpressions.

Two regular expressions may be joined by the infix operator ‘|’; the resulting regular expression matches any string matching either subexpression. For example, ‘abba|cde’ matches either the string abba or the string cde. Note that alternation does not work inside character classes, where ‘|’ has its literal meaning.

Repetition takes precedence over concatenation, which in turn takes precedence over alternation. A whole subexpression may be enclosed in parentheses to override these precedence rules.

The backreference ‘\N\’, where ‘N = 1 \ldots 9\’, matches the substring previously matched by the \( N \)th parenthesized subexpression of the regular expression. (This is an extension for extended regular expressions: POSIX defines them only for basic ones.)

**Perl-like Regular Expressions**

The perl = TRUE argument to grep, regexpr, gregexpr, sub, gsub and strsplit switches to the PCRE library that implements regular expression pattern matching using the same syntax and semantics as Perl 5.x, with just a few differences.

For complete details please consult the man pages for PCRE (and not PCRE2), especially man pcrepattern and man pcreapi, on your system or from the sources at http://www.pcre.org. (The version in use can be found by calling extSoftVersion. It need not be the version described in the system’s man page. As PCRE has been feature-frozen for some time (essentially 2012), the man pages at http://www.pcre.org/original/doc/html/ should be a good match.)

Perl regular expressions can be computed byte-by-byte or (UTF-8) character-by-character: the latter is used in all multibyte locales and if any of the inputs are marked as UTF-8 (see Encoding).

All the regular expressions described for extended regular expressions are accepted except ‘\<’ and ‘\>’: in Perl all backslashed metacharacters are alphanumeric and backslashed symbols always are interpreted as a literal character. ‘{’ is not special if it would be the start of an invalid interval specification. There can be more than 9 backreferences (but the replacement in sub can only refer to the first 9).

Character ranges are interpreted in the numerical order of the characters, either as bytes in a single-byte locale or as Unicode code points in UTF-8 mode. So in either case ‘[A-Za-z]’ specifies the set of ASCII letters.

In UTF-8 mode the named character classes only match ASCII characters: see ‘\p’ below for an alternative.

The construct ‘(?:\ldots\)’ is used for Perl extensions in a variety of ways depending on what immediately follows the ‘?’. Perl-like matching can work in several modes, set by the options ‘(?i)’ (caseless, equivalent to Perl’s ‘/i’), ‘(?m)’ (multiline, equivalent to Perl’s ‘/m’), ‘(?s)’ (single line, so a dot matches all characters, even new lines: equivalent to Perl’s ‘/s’) and ‘(?x)’ (extended, whitespace data
characters are ignored unless escaped and comments are allowed: equivalent to Perl’s ‘/x/’). These can be concatenated, so for example, ‘(?!m)’ sets caseless multiline matching. It is also possible to unset these options by preceding the letter with a hyphen, and to combine setting and unsettingsuch as ‘(?m-sx)’. These settings can be applied within patterns, and then apply to the remainder of the pattern. Additional options not in Perl include ‘(?U)’ to set ‘ungreedy’ mode (so matching is minimal unless ‘?’ is used as part of the repetition quantifier, when it is greedy). Initially none of these options are set.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between ‘\Q’ and ‘\E’. This is different from Perl in that ‘$’ and ‘@’ are handled as literals in ‘\Q...\E’ sequences in PCRE, whereas in Perl, ‘$’ and ‘@’ cause variable interpolation.

The escape sequences ‘\d’, ‘\s’ and ‘\w’ represent any decimal digit, space character and ‘word’ character (letter, digit or underscore in the current locale: in UTF-8 mode only ASCII letters and digits are considered) respectively, and their upper-case versions represent their negation. Vertical tab was not regarded as a space character in a C locale before PCRE 8.34. Sequences ‘\h’, ‘\v’, ‘\H’ and ‘\V’ match horizontal and vertical space or the negation. (In UTF-8 mode, these do match non-ASCII Unicode code points.)

There are additional escape sequences: ‘\cx’ is ‘c\nt\r\l-x’ for any ‘x’, ‘\d\dd’ is the octal character (for up to three digits unless interpretable as a backreference, as ‘\1’ to ‘\7’ always are), and ‘\xhh’ specifies a character by two hex digits. In a UTF-8 locale, ‘\x{h...}’ specifies a Unicode code point by one or more hex digits. (Note that some of these will be interpreted by R’s parser in literal character strings.)

Outside a character class, ‘\A’ matches at the start of a subject (even in multiline mode, unlike ‘^’), ‘\Z’ matches at the end of a subject or before a newline at the end, ‘\z’ matches only at end of a subject. and ‘\G’ matches at first matching position in a subject (which is subtly different from Perl’s end of the previous match). ‘\C’ matches a single byte, including a newline, but its use is warned against. In UTF-8 mode, ‘\R’ matches any Unicode newline character (not just CR), and ‘\X’ matches any number of Unicode characters that form an extended Unicode sequence.

In UTF-8 mode, some Unicode properties may be supported via ‘\p{xx}’ and ‘\P{xx}’ which match characters with and without property ‘xx’ respectively. For a list of supported properties see the PCRE documentation, but for example ‘\L’ is ‘upper case letter’ and ‘\S’ is ‘currency symbol’. (This support depends on the PCRE library being compiled with ‘Unicode property support’ which can be checked via pcre_config.)

The sequence ‘(?#’ marks the start of a comment which continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part at all in the pattern matching.

If the extended option is set, an unescaped ‘#’ character outside a character class introduces a comment that continues up to the next newline character in the pattern.

The pattern ‘(?:. . .)’ groups characters just as parentheses do but does not make a backreference.

Patterns ‘(?= . . . )’ and ‘(?! . . . )’ are zero-width positive and negative lookahead assertions: they match if an attempt to match the . . . forward from the current position would succeed (or not), but use up no characters in the string being processed. Patterns ‘(?<= . . . )’ and ‘(?<! . . . )’ are the lookbehind equivalents: they do not allow repetition quantifiers nor ‘\C’ in . . .

regexpr and gregexpr support ‘named capture’. If groups are named, e.g., “(?<first>[A-Za-Z][a-z]+)” then the positions of the matches are also returned by name. (Named backreferences are not supported by sub.)

Atomic grouping, possessive qualifiers and conditional and recursive patterns are not covered here.
regmatches

Extract or Replace Matched Substrings

Description

Extract or replace matched substrings from match data obtained by regexpr, gregexpr or regexec.

Usage

regmatches(x, m, invert = FALSE)
regmatches(x, m, invert = FALSE) <- value

Arguments

x a character vector
m an object with match data
invert a logical: if TRUE, extract or replace the non-matched substrings.
value an object with suitable replacement values for the matched or non-matched substrings (see Details).

Details

If invert is FALSE (default), regmatches extracts the matched substrings as specified by the match data. For vector match data (as obtained from regexpr), empty matches are dropped; for list match data, empty matches give empty components (zero-length character vectors).

If invert is TRUE, regmatches extracts the non-matched substrings, i.e., the strings are split according to the matches similar to strsplit (for vector match data, at most a single split is performed).

If invert is NA, regmatches extracts both non-matched and matched substrings, always starting and ending with a non-match (empty if the match occurred at the beginning or the end, respectively).

Note that the match data can be obtained from regular expression matching on a modified version of x with the same numbers of characters.

The replacement function can be used for replacing the matched or non-matched substrings. For vector match data, if invert is FALSE, value should be a character vector with length the number of matched elements in m. Otherwise, it should be a list of character vectors with the same length as m, each as long as the number of replacements needed. Replacement coerces values to character or list and generously recycles values as needed. Missing replacement values are not allowed.
Value

For regmatches, a character vector with the matched substrings if m is a vector and invert is FALSE. Otherwise, a list with the matched or/and non-matched substrings.

For regmatches<-, the updated character vector.

Examples

```r
x <- c("A and B", "A, B and C", "A, B, C and D", "foobar")
pattern <- "[[[space:]]]*([,|and][[space:]]"
## Match data from regexpr()
m <- regexpr(pattern, x)
regmatches(x, m)
regmatches(x, m, invert = TRUE)
## Match data from gregexpr()
m <- gregexpr(pattern, x)
regmatches(x, m)
regmatches(x, m, invert = TRUE)
```

```r
## Consider
x <- "John (fishing, hunting), Paul (hiking, biking)"
## Suppose we want to split at the comma (plus spaces) between the
## persons, but not at the commas in the parenthesized hobby lists.
## One idea is to "blank out" the parenthesized parts to match the
## parts to be used for splitting, and extract the persons as the
## non-matched parts.
## First, match the parenthesized hobby lists.
m <- gregexpr("\(\[^\)\]*\)", x)
## Write a little utility for creating blank strings with given numbers
## of characters.
blanks <- function(n) strrep(" ", n)
## Create a copy of x with the parenthesized parts blanked out.
s <- x
regmatches(s, m) <- Map(blanks, lapply(regmatches(s, m), nchar))
s
## Compute the positions of the split matches (note that we cannot call
## strsplit() on x with match data from s).
m <- gregexpr("", x", s)
## And finally extract the non-matched parts.
regmatches(x, m, invert = TRUE)
```

Description

`remove` and `rm` can be used to remove objects. These can be specified successively as character strings, or in the character vector `list`, or through a combination of both. All objects thus specified will be removed.

If `envir` is `NULL` then the currently active environment is searched first.

If `inherits` is `TRUE` then parents of the supplied directory are searched until a variable with the given name is encountered. A warning is printed for each variable that is not found.
Usage

```r
remove(..., list = character(), pos = -1,
       envir = as.environment(pos), inherits = FALSE)
```

```r
rm (..., list = character(), pos = -1,
     envir = as.environment(pos), inherits = FALSE)
```

Arguments

- `...`: the objects to be removed, as names (unquoted) or character strings (quoted).
- `list`: a character vector naming objects to be removed.
- `pos`: where to do the removal. By default, uses the current environment. See ‘details’ for other possibilities.
- `envir`: the environment to use. See ‘details’.
- `inherits`: should the enclosing frames of the environment be inspected?

Details

The `pos` argument can specify the environment from which to remove the objects in any of several ways: as an integer (the position in the `search` list); as the character string name of an element in the search list; or as an `environment` (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

It is not allowed to remove variables from the base environment and base namespace, nor from any environment which is locked (see `lockEnvironment`).

Earlier versions of R incorrectly claimed that supplying a character vector in `...` removed the objects named in the character vector, but it removed the character vector. Use the `list` argument to specify objects via a character vector.

References

See Also

`ls`, `objects`

Examples

```r
tmp <- 1:4
## work with tmp and cleanup
rm(tmp)

## Not run:
## remove (almost) everything in the working environment.
## You will get no warning, so don’t do this unless you are really sure.
rm(list = ls())

## End(Not run)
```
Description

rep replicates the values in x. It is a generic function, and the (internal) default method is described here.
rep.int and rep_len are faster simplified versions for two common cases. They are not generic.

Usage

rep(x, ...)

rep.int(x, times)

rep_len(x, length.out)

Arguments

x

a vector (of any mode including a list) or a factor or (for rep only) a POSIXct or POSIXlt or Date object; or an S4 object containing such an object.

... further arguments to be passed to or from other methods. For the internal default method these can include:
times an integer-valued vector giving the (non-negative) number of times to repeat each element if of length length(x), or to repeat the whole vector if of length 1. Negative or NA values are an error. A double vector is accepted, other inputs being coerced to an integer or double vector.

length.out non-negative integer. The desired length of the output vector. Ignored if NA or invalid.
each non-negative integer. Each element of x is repeated each times. Other inputs will be coerced to an integer or double vector and the first element taken. Treated as 1 if NA or invalid.
times, length.out see ... above.

Details

The default behaviour is as if the call was

rep(x, times = 1, length.out = NA, each = 1)

. Normally just one of the additional arguments is specified, but if each is specified with either of the other two, its replication is performed first, and then that implied by times or length.out.
If times consists of a single integer, the result consists of the whole input repeated this many times.
If times is a vector of the same length as x (after replication by each), the result consists of x[1] repeated times[1] times, x[2] repeated times[2] times and so on.
length.out may be given in place of times, in which case x is repeated as many times as is necessary to create a vector of this length. If both are given, length.out takes priority and times is ignored.
Non-integer values of \texttt{times} will be truncated towards zero. If \texttt{times} is a computed quantity it is prudent to add a small fuzz or use \texttt{round}. And analogously for each.

If \texttt{x} has length zero and \texttt{length.out} is supplied and is positive, the values are filled in using the extraction rules, that is by an NA of the appropriate class for an atomic vector (0 for raw vectors) and \texttt{NULL} for a list.

\section*{Value}

An object of the same type as \texttt{x}.

\texttt{rep.int} and \texttt{rep_len} return no attributes (except the class if returning a factor).

The default method of \texttt{rep} gives the result names (which will almost always contain duplicates) if \texttt{x} had names, but retains no other attributes.

\section*{Note}

Function \texttt{rep.int} is a simple case which was provided as a separate function partly for S compatibility and partly for speed (especially when names can be dropped). The performance of \texttt{rep} has been improved since, but \texttt{rep.int} is still at least twice as fast when \texttt{x} has names.

The name \texttt{rep.int} long precedes making \texttt{rep} generic.

Function \texttt{rep} is a primitive, but (partial) matching of argument names is performed as for normal functions.

For historical reasons \texttt{rep} (only) works on \texttt{NULL}: the result is always \texttt{NULL} even when \texttt{length.out} is positive.

Although it has never been documented, these functions have always worked on \texttt{expression} vectors.

\section*{See Also}

\texttt{seq}, \texttt{sequence}, \texttt{replicate}.

\section*{Examples}

\begin{verbatim}
rep(1:4, 2)
rep(1:4, each = 2)  # not the same.
rep(1:4, c(2,2,2,2))  # same as second.
rep(1:4, c(2,1,2,1))
rep(1:4, each = 2, len = 4)  # first 4 only.
rep(1:4, each = 2, len = 10)  # 8 integers plus two recycled 1's.
rep(1:4, each = 2, times = 3)  # length 24, 3 complete replications

rep(1, 40*(1-.8))  # length 7 on most platforms
rep(1, 40*(1-.8)+1e-7)  # better

## replicate a list
fred <- list(happy = 1:10, name = "squash")
rep(fred, 5)

# date-time objects
x <- .leap.seconds[1:3]
\end{verbatim}
replace

\[
\text{replace}(x, 2) \\
\text{rep(as.POSIXlt}(x), \text{rep}(2, 3))
\]

## named factor
\[
x \leftarrow \text{factor}(\text{LETTERS}[1:4]); \text{names}(x) \leftarrow \text{letters}[1:4] \\
x \\
\text{rep}(x, 2) \\
\text{rep}(x, \text{each} = 2) \\
\text{rep.int}(x, 2) \ # \text{no names} \\
\text{rep_len}(x, 10)
\]

---

**replace**

*Replace Values in a Vector*

**Description**

`replace` replaces the values in `x` with indices given in `list` by those given in `values`. If necessary, the values in `values` are recycled.

**Usage**

`replace(x, list, values)`

**Arguments**

- `x` vector
- `list` an index vector
- `values` replacement values

**Value**

A vector with the values replaced.

**Note**

`x` is unchanged: remember to assign the result.

**References**

Reserved Words in R

Description

The reserved words in R’s parser are

```
if else repeat while function for in next break
TRUE FALSE NULL Inf NaN NA_integer_ NA_real_ NA_complex_ NA_character_
```

... and ..1, ..2 etc, which are used to refer to arguments passed down from a calling function, see ....

Details

Reserved words outside quotes are always parsed to be references to the objects linked to in the ‘Description’, and hence they are not allowed as syntactic names (see `make.names`). They are allowed as non-syntactic names, e.g. inside backtick quotes.

rev

Reverse Elements

Description

`rev` provides a reversed version of its argument. It is generic function with a default method for vectors and one for `dendrograms`.

Note that this is no longer needed (nor efficient) for obtaining vectors sorted into descending order, since that is now rather more directly achievable by `sort(x, decreasing = TRUE)`.

Usage

`rev(x)`

Arguments

`x` a vector or another object for which reversal is defined.

References

See Also

`seq`, `sort`.

Examples

```
x <- c(1:5, 5:3)
## sort into descending order; first more efficiently:
stopifnot(sort(x, decreasing = TRUE) == rev(sort(x)))
stopifnot(rev(1:7) == 7:1)  # don’t need `rev` here
```
Rhome

Return the R Home Directory

Description

Return the R home directory, or the full path to a component of the R installation.

Usage

R.home(component = "home")

Arguments

component As well as "home" which gives the R home directory, other known values are "bin", "doc", "etc", "include", "modules" and "share" giving the paths to the corresponding parts of an R installation.

Details

The R home directory is the top-level directory of the R installation being run.

The R home directory is often referred to as R_HOME, and is the value of an environment variable of that name in an R session. It can be found outside an R session by R RHOME.

Value

A character string giving the R home directory or path to a particular component. Normally the components are all subdirectories of the R home directory, but this need not be the case in a Unix-like installation.

The value for "modules" and on Windows "bin" is a sub-architecture-specific location.

On a Unix-alike, the constructed paths are based on the current values of the environment variables R_HOME and where set R_SHARE_DIR, R_DOC_DIR and R_INCLUDE_DIR (these are set on startup and should not be altered).

On Windows the values of R.home() and R_HOME are switched to the 8.3 short form of path elements if required and if the Windows service to do that is enabled. The value of R_HOME is set to use forward slashes (since many package maintainers pass it unquoted to shells, for example in 'Makefile's).

rle

Run Length Encoding

Description

Compute the lengths and values of runs of equal values in a vector – or the reverse operation.
Usage

rle(x)
inverse.rle(x, ...)

## S3 method for class 'rle'
print(x, digits = getOption("digits"), prefix = "", ...)  

Arguments

x       a vector (atomic, not a list) for rle(); an object of class "rle" for inverse.rle().
...     further arguments; ignored here.
digits  number of significant digits for printing. see print.default.
prefix  character string, prepended to each printed line.

Details

'vector' is used in the sense of is.vector.
Missing values are regarded as unequal to the previous value, even if that is also missing.
inverse.rle() is the inverse function of rle(), reconstructing x from the runs.

Value

rle() returns an object of class "rle" which is a list with components:

lengths  an integer vector containing the length of each run.
values   a vector of the same length as lengths with the corresponding values.

inverse.rle() returns an atomic vector.

Examples

x <- rev(rep(6:10, 1:5))
rle(x)
## lengths [1:5] 5 4 3 2 1
## values [1:5] 10 9 8 7 6

z <- c(TRUE, TRUE, FALSE, FALSE, TRUE, FALSE, TRUE, TRUE, TRUE)
rle(z)
rle(as.character(z))
print(rle(z), prefix = "..| ")

N <- integer(0)
stopifnot(x == inverse.rle(rle(x)),
          identical(N, inverse.rle(rle(N))),
          z == inverse.rle(rle(z)))
**Round**

**Rounding of Numbers**

**Description**

- **ceiling** takes a single numeric argument `x` and returns a numeric vector containing the smallest integers not less than the corresponding elements of `x`.

- **floor** takes a single numeric argument `x` and returns a numeric vector containing the largest integers not greater than the corresponding elements of `x`.

- **trunc** takes a single numeric argument `x` and returns a numeric vector containing the integers formed by truncating the values in `x` toward 0.

- **round** rounds the values in its first argument to the specified number of decimal places (default 0).

- **signif** rounds the values in its first argument to the specified number of significant digits.

**Usage**

- `ceiling(x)`
- `floor(x)`
- `trunc(x, ...)`
- `round(x, digits = 0)`
- `signif(x, digits = 6)`

**Arguments**

- `x` a numeric vector. Or, for `round` and `signif`, a complex vector.
- `digits` integer indicating the number of decimal places (`round`) or significant digits (`signif`) to be used. Negative values are allowed (see ‘Details’).
- `...` arguments to be passed to methods.

**Details**

These are generic functions: methods can be defined for them individually or via the Math group generic.

Note that for rounding off a 5, the IEC 60559 standard is expected to be used, ‘go to the even digit’. Therefore `round(0.5)` is 0 and `round(-1.5)` is -2. However, this is dependent on OS services and on representation error (since e.g. 0.15 is not represented exactly, the rounding rule applies to the represented number and not to the printed number, and so `round(0.15, 1)` could be either 0.1 or 0.2).

Rounding to a negative number of digits means rounding to a power of ten, so for example `round(x, digits = -2)` rounds to the nearest hundred.

For `signif` the recognized values of `digits` are 1...22, and non-missing values are rounded to the nearest integer in that range. Complex numbers are rounded to retain the specified number of digits in the larger of the components. Each element of the vector is rounded individually, unlike printing.

These are all primitive functions.
S4 methods

These are all (internally) S4 generic.

ceiling, floor and trunc are members of the Math group generic. As an S4 generic, trunc has only one argument.

round and signif are members of the Math2 group generic.

Warning

The realities of computer arithmetic can cause unexpected results, especially with floor and ceiling. For example, we ‘know’ that floor(log(x, base = 8)) for x = 8 is 1, but 0 has been seen on an R platform. It is normally necessary to use a tolerance.

References

See Also

as.integer.

Examples

round(.5 + -2:4) # IEEE rounding: -2 0 0 2 2 4 4
( x1 <- seq(-2, 4, by = .5) )
round(x1) #-- IEEE rounding !
x1[trunc(x1) != floor(x1)]
x1[round(x1) != floor(x1 + .5)]

(non.int <- ceiling(x1) != floor(x1))

x2 <- pi * 100^(-1:3)
round(x2, 3)
signif(x2, 3)

round.POSIXt Round / Truncate Data-Time Objects

Description

Round or truncate date-time objects.

Usage

## S3 method for class 'POSIXt'
round(x, units = c("secs", "mins", "hours", "days"))

## S3 method for class 'POSIXt'
trunc(x, units = c("secs", "mins", "hours", "days"), ...)

## S3 method for class 'Date'
round(x, ...)

## S3 method for class 'Date'
trunc(x, ...)
Arguments

x an object inheriting from "POSIXt" or "Date".
units one of the units listed. Can be abbreviated.
... arguments to be passed to or from other methods, notably digits for round.

Details

The time is rounded or truncated to the second, minute, hour or day. Time zones are only relevant to days, when midnight in the current time zone is used.
The methods for class "Date" are of little use except to remove fractional days.

Value

An object of class "POSIXlt" or "Date".

See Also

round for the generic function and default methods.
DateTimeClasses, Date

Examples

round(.leap.seconds + 1000, "hour")
trunc(Sys.time(), "day")

row

Row Indexes

Description

Returns a matrix of integers indicating their row number in a matrix-like object, or a factor indicating the row labels.

Usage

row(x, as.factor = FALSE)
.row(dim)

Arguments

x a matrix-like object, that is one with a two-dimensional dim.
dim a matrix dimension, i.e., integer vector of length two (with non-negative entries).
as.factor a logical value indicating whether the value should be returned as a factor of row labels (created if necessary) rather than as numbers.

Value

An integer (or factor) matrix with the same dimensions as x and whose i,j-th element is equal to i (or the i-th row label).
References

See Also

`col` to get columns.

Examples

```r
x <- matrix(1:12, 3, 4)
# extract the diagonal of a matrix - more slowly than diag(x)
dx <- x[row(x) == col(x)]
dx

# create an identity 5-by-5 matrix more slowly than diag(n = 5):
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1
x
```

Description

Retrieve or set the row or column names of a matrix-like object.

Usage

```
rownames(x, do.NULL = TRUE, prefix = "row")
rownames(x) <- value

colnames(x, do.NULL = TRUE, prefix = "col")
colnames(x) <- value
```

Arguments

- `x`: a matrix-like R object, with at least two dimensions for `colnames`.
- `do.NULL`: logical. If `FALSE` and names are `NULL`, names are created.
- `prefix`: for created names.
- `value`: a valid value for that component of `dimnames(x)`. For a matrix or array this is either `NULL` or a character vector of non-zero length equal to the appropriate dimension.

Details

The extractor functions try to do something sensible for any matrix-like object `x`. If the object has `dimnames` the first component is used as the row names, and the second component (if any) is used for the column names. For a data frame, `rownames` and `colnames` eventually call `row.names` and `names` respectively, but the latter are preferred.
If `do.NULL` is `FALSE`, a character vector (of length `NROW(x)` or `NCOL(x)`) is returned in any case, prepending prefix to simple numbers, if there are no dimnames or the corresponding component of the dimnames is `NULL`.

The replacement methods for arrays/matrices coerce vector and factor values of `value` to character, but do not dispatch methods for `as.character`.

For a data frame, `value` for `rownames` should be a character vector of non-duplicated and non-missing names (this is enforced), and for `colnames` a character vector of (preferably) unique syntactically-valid names. In both cases, `value` will be coerced by `as.character`, and setting `colnames` will convert the row names to character.

**Note**

If the replacement versions are called on a matrix without any existing dimnames, they will add suitable dimnames. But constructions such as

```r
rownames(x)[3] <- "c"
```

may not work unless `x` already has dimnames, since this will create a length-3 value from the `NULL` value of `rownames(x)`.

**See Also**

`dimnames`, `case.names`, `variable.names`.

**Examples**

```r
m0 <- matrix(NA, 4, 0)
rownames(m0)

m2 <- cbind(1, 1:4)
colnames(m2, do.NULL = FALSE)
colnames(m2) <- c("x","y")
rownames(m2) <- rownames(m2, do.NULL = FALSE, prefix = "Obs.")
m2
```

---

**row.names**

*Get and Set Row Names for Data Frames*

**Description**

All data frames have a row names attribute, a character vector of length the number of rows with no duplicates nor missing values.

For convenience, these are generic functions for which users can write other methods, and there are default methods for arrays. The description here is for the `data.frame` method.

**Usage**

```r
row.names(x)
row.names(x) <- value
```
Arguments

- **x**: object of class "data.frame", or any other class for which a method has been defined.
- **value**: an object to be coerced to character unless an integer vector. It should have (after coercion) the same length as the number of rows of \( x \) with no duplicated nor missing values. NULL is also allowed: see 'Details'.

Details

A data frame has (by definition) a vector of row names which has length the number of rows in the data frame, and contains neither missing nor duplicated values. Where a row names sequence has been added by the software to meet this requirement, they are regarded as 'automatic'.

Row names are currently allowed to be integer or character, but for backwards compatibility (with \( R \leq 2.4.0 \)) row.names will always return a character vector. (Use \( \text{attr}(x, "row.names") \) if you need to retrieve an integer-valued set of row names.)

Using NULL for the value resets the row names to \( \text{seq}\_\text{len}(\text{nrow}(x)) \), regarded as 'automatic'.

Value

- `row.names` returns a character vector.
- `row.names<-` returns a data frame with the row names changed.

Note

`row.names` is similar to `rownames` for arrays, and it has a method that calls `rownames` for an array argument.

Row names of the form \( 1:n \) for \( n > 2 \) are stored internally in a compact form, which might be seen from C code or by deparsing but never via `row.names` or `attr(x, "row.names")`. Additionally, some names of this sort are marked as 'automatic' and handled differently by `as.matrix` and `data.matrix` (and potentially other functions). (All zero-row data frames are regarded as having automatic row.names.)

References

See Also

- `data.frame`, `rownames`, `names`
- `.row_names_info` for the internal representations.
rowsum

Give Column Sums of a Matrix or Data Frame, Based on a Grouping Variable

Description

Compute column sums across rows of a numeric matrix-like object for each level of a grouping variable. rowsum is generic, with a method for data frames and a default method for vectors and matrices.

Usage

rowsum(x, group, reorder = TRUE, ...)  
## S3 method for class 'data.frame'
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)  
## Default S3 method:
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)

Arguments

x  
a matrix, data frame or vector of numeric data. Missing values are allowed. A numeric vector will be treated as a column vector.

group  
a vector or factor giving the grouping, with one element per row of x. Missing values will be treated as another group and a warning will be given.

reorder  
if TRUE, then the result will be in order of sort(unique(group)), if FALSE, it will be in the order that groups were encountered.

na.rm  
logical (TRUE or FALSE). Should NA (including NaN) values be discarded?

...  
other arguments to be passed to or from methods

Details

The default is to reorder the rows to agree with tapply as in the example below. Reordering should not add noticeably to the time except when there are very many distinct values of group and x has few columns.

The original function was written by Terry Therneau, but this is a new implementation using hashing that is much faster for large matrices.

To sum over all the rows of a matrix (ie, a single group) use colSums, which should be even faster.

For integer arguments, over/underflow in forming the sum results in NA.

Value

A matrix or data frame containing the sums. There will be one row per unique value of group.

See Also

tapply, aggregate, rowSums
Examples

```r
require(stats)

x <- matrix(runif(100), ncol = 5)
group <- sample(1:8, 20, TRUE)
(xsum <- rowsum(x, group))
## Slower versions
tapply(x, list(group[row(x)], col(x)), sum)
t(sapply(split(as.data.frame(x), group), colSums))
aggregate(x, list(group), sum)[-1]
```

---

### sample

**Random Samples and Permutations**

**Description**

`sample` takes a sample of the specified size from the elements of `x` using either with or without replacement.

**Usage**

```r
sample(x, size, replace = FALSE, prob = NULL)
sample.int(n, size = n, replace = FALSE, prob = NULL,
    useHash = (!replace && is.null(prob) && size <= n/2 && n > 1e7))
```

**Arguments**

- `x` either a vector of one or more elements from which to choose, or a positive integer. See ‘Details.’
- `n` a positive number, the number of items to choose from. See ‘Details.’
- `size` a non-negative integer giving the number of items to choose.
- `replace` should sampling be with replacement?
- `prob` a vector of probability weights for obtaining the elements of the vector being sampled.
- `useHash` logical indicating if the hash-version of the algorithm should be used. Can only be used for `replace = FALSE, prob = NULL, and size <= n/2, and really should be used for large `n`, as `useHash=FALSE` will use memory proportional to `n`.

**Details**

If `x` has length 1, is numeric (in the sense of `is.numeric`) and `x >= 1`, sampling via `sample` takes place from `1:x`. *Note* that this convenience feature may lead to undesired behaviour when `x` is of varying length in calls such as `sample(x)`. See the examples.

Otherwise `x` can be any R object for which `length` and subsetting by integers make sense: S3 or S4 methods for these operations will be dispatched as appropriate.

For `sample` the default for `size` is the number of items inferred from the first argument, so that `sample(x)` generates a random permutation of the elements of `x` (or `1:x`).
It is allowed to ask for \( \text{size} = 0 \) samples with \( n = 0 \) or a length-zero \( x \), but otherwise \( n > 0 \) or positive \( \text{length}(x) \) is required. 

Non-integer positive numerical values of \( n \) or \( x \) will be truncated to the next smallest integer, which has to be no larger than \( \text{Machine}\$\text{integer}\_\text{max} \).

The optional \( \text{prob} \) argument can be used to give a vector of weights for obtaining the elements of the vector being sampled. They need not sum to one, but they should be non-negative and not all zero. If \( \text{replace} \) is true, Walker’s alias method (Ripley, 1987) is used when there are more than 200 reasonably probable values: this gives results incompatible with those from \( \text{R} < 2.2.0 \).

If \( \text{replace} \) is false, these probabilities are applied sequentially, that is the probability of choosing the next item is proportional to the weights amongst the remaining items. The number of nonzero weights must be at least \( \text{size} \) in this case.

\( \text{sample}\_\text{int} \) is a bare interface in which both \( n \) and \( \text{size} \) must be supplied as integers.

Argument \( n \) can be larger than the largest integer of type \( \text{integer} \), up to the largest representable integer in type \( \text{double} \). Only uniform sampling is supported. Two random numbers are used to ensure uniform sampling of large integers.

**Value**

For \( \text{sample} \) a vector of length \( \text{size} \) with elements drawn from either \( x \) or from the integers \( 1:x \).

For \( \text{sample}\_\text{int} \), an integer vector of length \( \text{size} \) with elements from \( 1:n \), or a double vector if \( n \geq 2^{31} \).

**References**

**See Also**

\( \text{RNG} \) about random number generation.

CRAN package *sampling* for other methods of weighted sampling without replacement.

**Examples**

```r
x <- 1:12
# a random permutation
sample(x)
# bootstrap resampling -- only if length(x) > 1 !
sample(x, replace = TRUE)

# 100 Bernoulli trials
sample(c(0,1), 100, replace = TRUE)

## More careful bootstrapping -- Consider this when using sample()
## programmatically (i.e., in your function or simulation)!

# sample()’s surprise -- example
x <- 1:10
sample(x[x > 8]) # length 2
sample(x[x > 9]) # oops -- length 10!
sample(x[x > 10]) # length 0
```
## safer version:
resample <- function(x, ...) x[sample.int(length(x), ...)]
resample(x[x > 8]) # length 2
resample(x[x > 9]) # length 1
resample(x[x > 10]) # length 0

## R 3.x.y only
sample.int(1e10, 12, replace = TRUE)
sample.int(1e10, 12) # not that there is much chance of duplicates

---

save

Save R Objects

Description

save writes an external representation of R objects to the specified file. The objects can be read back from the file at a later date by using the function load or attach (or data in some cases).

save.image() is just a short-cut for 'save my current workspace', i.e.,
save(list = ls(all.names = TRUE), file = "RData", envir = .GlobalEnv). It is also what happens with q("yes").

Usage

save(..., list = character(),
    file = stop("'file' must be specified"),
    ascii = FALSE, version = NULL, envir = parent.frame(),
    compress = isTRUE(!ascii), compression_level,
    eval.promises = TRUE, precheck = TRUE)

save.image(file = "RData", version = NULL, ascii = FALSE,
            compress = !ascii, safe = TRUE)

Arguments

... the names of the objects to be saved (as symbols or character strings).
list A character vector containing the names of objects to be saved.
file a (writable binary-mode) connection or the name of the file where the data will be saved (when tilde expansion is done). Must be a file name for save.image or version = 1.
ascii if TRUE, an ASCII representation of the data is written. The default value of ascii is FALSE which leads to a binary file being written. If NA and version >= 2, a different ASCII representation is used which writes double/complex numbers as binary fractions.
version the workspace format version to use. NULL specifies the current default format. The version used from R 0.99.0 to R 1.3.1 was version 1. The default format as from R 1.4.0 is version 2.
envir environment to search for objects to be saved.
compress  
logical or character string specifying whether saving to a named file is to use compression. TRUE corresponds to gzip compression, and character strings "gzip", "bzip2" or "xz" specify the type of compression. Ignored when file is a connection and for workspace format version 1.

compression_level  
integer: the level of compression to be used. Defaults to 6 for gzip compression and to 9 for bzip2 or xz compression.

eval.promises  
logical: should objects which are promises be forced before saving?

precheck  
logical: should the existence of the objects be checked before starting to save (and in particular before opening the file/connection)? Does not apply to version 1 saves.

safe  
logical. If TRUE, a temporary file is used for creating the saved workspace. The temporary file is renamed to file if the save succeeds. This preserves an existing workspace file if the save fails, but at the cost of using extra disk space during the save.

Details

The names of the objects specified either as symbols (or character strings) in ... or as a character vector in list are used to look up the objects from environment envir. By default promises are evaluated, but if eval.promises = FALSE promises are saved (together with their evaluation environments). (Promises embedded in objects are always saved unevaluated.)

All R platforms use the XDR (bigendian) representation of C ints and doubles in binary save-d files, and these are portable across all R platforms.

ASCII saves used to be useful for moving data between platforms but are now mainly of historical interest. They can be more compact than binary saves where compression is not used, but are almost always slower to both read and write: binary saves compress much better than ASCII ones. Further, decimal ASCII saves may not restore double/complex values exactly, and what value is restored may depend on the R platform.

Default values for the ascii, compress, safe and version arguments can be modified with the "save.defaults" option (used both by save and save.image), see also the 'Examples' section. If a "save.image.defaults" option is set it is used in preference to "save.defaults" for function save.image (which allows this to have different defaults). In addition, compression_level can be part of the "save.defaults" option.

A connection that is not already open will be opened in mode "wb". Supplying a connection which is open and not in binary mode gives an error.

Compression

Large files can be reduced considerably in size by compression. A particular 46MB R object was saved as 35MB without compression in 2 seconds, 22MB with gzip compression in 8 secs, 19MB with bzip2 compression in 13 secs and 9.4MB with xz compression in 40 secs. The load times were 1.3, 2.8, 5.5 and 5.7 seconds respectively. These results are indicative, but the relative performances do depend on the actual file: xz compressed unusually well here.

It is possible to compress later (with gzip, bzip2 or xz) a file saved with compress = FALSE: the effect is the same as saving with compression. Also, a saved file can be uncompressed and re-compressed under a different compression scheme (and see resaveRdaFiles for a way to do so from within R).
Parallel compression

That file can be a connection can be exploited to make use of an external parallel compression utility such as pigz (http://zlib.net/pigz/) or pbzip2 (http://compression.ca/pbzip2/) via a pipe connection. For example, using 8 threads,

```r
con <- pipe("pigz -p8 > fname.gz", "wb")
save(myObj, file = con); close(con)

con <- pipe("pbzip2 -p8 -9 > fname.bz2", "wb")
save(myObj, file = con); close(con)

con <- pipe("xz -T8 -6 -e > fname.xz", "wb")
save(myObj, file = con); close(con)
```

where the last requires xz 5.1.1 or later built with support for multiple threads (and parallel compression is only effective for large objects: at level 6 it will compress in serialized chunks of 12MB).

Warnings

The ... arguments only give the names of the objects to be saved: they are searched for in the environment given by the envir argument, and the actual objects given as arguments need not be those found.

Saved R objects are binary files, even those saved with ascii = TRUE, so ensure that they are transferred without conversion of end-of-line markers and of 8-bit characters. The lines are delimited by LF on all platforms.

Although the default version has not changed since R 1.4.0, this does not mean that saved files are necessarily backwards compatible. You will be able to load a saved image into an earlier version of R unless use is made of later additions (for example, raw vectors, external pointers and some S4 objects).

One such ‘later addition’ was long vectors, introduced in R 3.0.0 and loadable only on 64-bit platforms.

Loading files saved with ASCII = NA requires a C99-compliant C function sscanf: this is a problem on Windows, first worked around in R 3.1.2: they should be readable in earlier versions of R on all other platforms.

Note

The most common reason for failure is lack of write permission in the current directory. For save.image and for saving at the end of a session this will shown by messages like

```
Error in gzfile(file, "wb") : unable to open connection
In addition: Warning message:
In gzfile(file, "wb") :
  cannot open compressed file '.RDataTmp',
  probable reason 'Permission denied'
```

scale

Scaling and Centering of Matrix-like Objects

Description
scale is generic function whose default method centers and/or scales the columns of a numeric matrix.

Usage
scale(x, center = TRUE, scale = TRUE)

Arguments
x
a numeric matrix(like object).

center
either a logical value or a numeric vector of length equal to the number of columns of x.

scale
either a logical value or a numeric vector of length equal to the number of columns of x.

Details
The value of center determines how column centering is performed. If center is a numeric vector with length equal to the number of columns of x, then each column of x has the corresponding value from center subtracted from it. If center is TRUE then centering is done by subtracting the column means (omitting NAs) of x from their corresponding columns, and if center is FALSE, no centering is done.

The value of scale determines how column scaling is performed (after centering). If scale is a numeric vector with length equal to the number of columns of x, then each column of x is divided by the corresponding value from scale. If scale is TRUE then scaling is done by dividing the (centered) columns of x by their standard deviations if center is TRUE, and the root mean square otherwise. If scale is FALSE, no scaling is done.

The root-mean-square for a (possibly centered) column is defined as \(\sqrt{\sum(x^2)/(n-1)}\), where x is a vector of the non-missing values and n is the number of non-missing values. In the case center = TRUE, this is the same as the standard deviation, but in general it is not. (To scale by the standard deviations without centering, use scale(x, center = FALSE, scale = apply(x, 2, sd, na.rm = TRUE)).)
460

scan

Value
For scale.default, the centered, scaled matrix. The numeric centering and scalings used (if any)
are returned as attributes "scaled:center" and "scaled:scale"
References
Brooks/Cole.
See Also
sweep which allows centering (and scaling) with arbitrary statistics.
For working with the scale of a plot, see par.
Examples
require(stats)
x <- matrix(1:10, ncol = 2)
(centered.x <- scale(x, scale = FALSE))
cov(centered.scaled.x <- scale(x)) # all 1

scan

Read Data Values

Description
Read data into a vector or list from the console or file.
Usage
scan(file = "", what = double(), nmax = -1, n = -1, sep = "",
quote = if(identical(sep, "\n")) "" else "'\"", dec = ".",
skip = 0, nlines = 0, na.strings = "NA",
flush = FALSE, fill = FALSE, strip.white = FALSE,
quiet = FALSE, blank.lines.skip = TRUE, multi.line = TRUE,
comment.char = "", allowEscapes = FALSE,
fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)
Arguments
file

the name of a file to read data values from. If the specified file is "", then input
is taken from the keyboard (or whatever stdin() reads if input is redirected or
R is embedded). (In this case input can be terminated by a blank line or an EOF
signal, ‘Ctrl-D’ on Unix and ‘Ctrl-Z’ on Windows.)
Otherwise, the file name is interpreted relative to the current working directory
(given by getwd()), unless it specifies an absolute path. Tilde-expansion is
performed where supported. When running R from a script, file = "stdin"
can be used to refer to the process’s stdin file stream.
This can be a compressed file (see file).
Alternatively, file can be a connection, which will be opened if necessary,
and if so closed at the end of the function call. Whatever mode the connection


is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line and so will match sep = "\n".

date can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for url.)

To read a data file not in the current encoding (for example a Latin-1 file in a UTF-8 locale or conversely) use a file connection setting its encoding argument (or scan’s fileEncoding argument).

what the type of what gives the type of data to be read. (Here ‘type’ is used in the sense of typeof.) The supported types are logical, integer, numeric, complex, character, raw and list. If what is a list, it is assumed that the lines of the data file are records each containing length(what) items (‘fields’) and the list components should have elements which are one of the first six (atomic) types listed or NULL, see section ‘Details’ below.

nmax integer: the maximum number of data values to be read, or if what is a list, the maximum number of records to be read. If omitted or not positive or an invalid value for an integer (and nlines is not set to a positive value), scan will read to the end of file.

n integer: the maximum number of data values to be read, defaulting to no limit. Invalid values will be ignored.

sep by default, scan expects to read ‘white-space’ delimited input fields. Alternatively, sep can be used to specify a character which delimits fields. A field is always delimited by an end-of-line marker unless it is quoted.

If specified this should be the empty character string (the default) or NULL or a character string containing just one single-byte character.

quote the set of quoting characters as a single character string or NULL. In a multibyte locale the quoting characters must be ASCII (single-byte).

dec decimal point character. This should be a character string containing just one single-byte character. (NULL and a zero-length character vector are also accepted, and taken as the default.)

skip the number of lines of the input file to skip before beginning to read data values.

nlines if positive, the maximum number of lines of data to be read.

na.strings character vector. Elements of this vector are to be interpreted as missing (NA) values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. Note that the test happens after white space is stripped from the input, so na.strings values may need their own white space stripped in advance.

flush logical: if TRUE, scan will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field, but precludes putting more that one record on a line.

fill logical: if TRUE, scan will implicitly add empty fields to any lines with fewer fields than implied by what.

strip.white vector of logical value(s) corresponding to items in the what argument. It is used only when sep has been specified, and allows the stripping of leading and trailing ‘white space’ from character fields (numeric fields are always stripped). Note: white space inside quoted strings is not stripped.

If strip.white is of length 1, it applies to all fields; otherwise, if strip.white[i] is TRUE and the i-th field is of mode character (because what[i] is) then the leading and trailing unquoted white space from field i is stripped.
quiet logical: if FALSE (default), scan() will print a line, saying how many items have been read.

blank.lines.skip logical: if TRUE blank lines in the input are ignored, except when counting skip and nlines.

multi.line logical: Only used if what is a list. If FALSE, all of a record must appear on one line (but more than one record can appear on a single line). Note that using fill = TRUE implies that a record will be terminated at the end of a line.

comment.char character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether (the default).

allowEscapes logical. Should C-style escapes such as `\n` be processed (the default) or read verbatim? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character).

fileEncoding character string: if non-empty declares the encoding used on a file (not a connection nor the keyboard) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file, and the ‘R Data Import/Export Manual’.

encoding encoding to be assumed for input strings. If the value is "latin1" or "UTF-8" it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input (see fileEncoding). See also ‘Details’.

text character string: if file is not supplied and this is, then data are read from the value of text via a text connection.

skipNul logical: should nuls be skipped when reading character fields?

Details

The value of what can be a list of types, in which case scan returns a list of vectors with the types given by the types of the elements in what. This provides a way of reading columnar data. If any of the types is NULL, the corresponding field is skipped (but a NULL component appears in the result).

The type of what or its components can be one of the six atomic vector types or NULL (see is.atomic).

‘White space’ is defined for the purposes of this function as one or more contiguous characters from the set space, horizontal tab, carriage return and line feed. It does not include form feed nor vertical tab, but in Latin-1 and Windows 8-bit locales (but not UTF-8) ‘space’ includes the non-breaking space ‘\xa0’.

Empty numeric fields are always regarded as missing values. Empty character fields are scanned as empty character vectors, unless na.strings contains "" when they are regarded as missing values.

The allowed input for a numeric field is optional whitespace followed either NA or an optional sign followed by a decimal or hexadecimal constant (see NumericConstants), or NaN, Inf or infinity (ignoring case). Out-of-range values are recorded as Inf, -Inf or 0.

For an integer field the allowed input is optional whitespace, followed by either NA or an optional sign and one or more digits ('0-9'): all out-of-range values are converted to NA_integer_.

If sep is the default (""), the character ‘\' in a quoted string escapes the following character, so quotes may be included in the string by escaping them.
If `sep` is non-default, the fields may be quoted in the style of '.csv' files where separators inside quotes (' ' or "") are ignored and quotes may be put inside strings by doubling them. However, if `sep = "\n"` it is assumed by default that one wants to read entire lines verbatim.

Quoting is only interpreted in character fields and in `NULL` fields (which might be skipping character fields).

Note that since `sep` is a separator and not a terminator, reading a file by `scan("foo", sep = "\n", blank.lines.skip = FALSE)` will give an empty final line if the file ends in a linefeed and not if it does not. This might not be what you expected; see also `readLines`.

If `comment.char` occurs (except inside a quoted character field), it signals that the rest of the line should be regarded as a comment and be discarded. Lines beginning with a comment character (possibly after white space with the default separator) are treated as blank lines.

There is a line-length limit of 4095 bytes when reading from the console (which may impose a lower limit: see ‘An Introduction to R’).

There is a check for a user interrupt every 1000 lines if `what` is a list, otherwise every 10000 items.

If `file` is a character string and `fileEncoding` is non-default, or if it is a not-already-open connection with a non-default encoding argument, the text is converted to UTF-8 and declared as such (and the encoding argument to `scan` is ignored). See the examples of `readLines`.

Embedded nulls in the input stream will terminate the field currently being read, with a warning once per call to `scan`. Setting `skipNul = TRUE` causes them to be ignored.

### Value

If `what` is a list, a list of the same length and same names (as any) as `what`.

Otherwise, a vector of the type of `what`.

Character strings in the result will have a declared encoding if `encoding` is "latin1" or "UTF-8".

### Note

The default for `multi.line` differs from S. To read one record per line, use `flush = TRUE` and `multi.line = FALSE`. (Note that quoted character strings can still include embedded newlines.)

If number of items is not specified, the internal mechanism re-allocates memory in powers of two and so could use up to three times as much memory as needed. (It needs both old and new copies.)

If you can, specify either `n` or `nmax` whenever inputting a large vector, and `nmax` or `nlines` when inputting a large list.

Using `scan` on an open connection to read partial lines can lose chars: use an explicit separator to avoid this.

Having null bytes in fields (including ‘\0’ if `allowEscapes = TRUE`) may lead to interpretation of the field being terminated at the null. They not normally present in text files – see `readBin`.

seek

Examples

search()
searchpaths()

Description

Functions to re-position connections.

Usage

seek(con, 
## S3 method for class 'connection'
seek(con, where = NA, origin = "start", rw = ",", 

isSeekable(con)

truncate(con, 

Arguments

con a connection.
where numeric. A file position (relative to the origin specified by origin), or NA.
rw character string. Empty or "read" or "write", partial matches allowed.
origin character string. One of "start", "current", "end": see ‘Details’.
... further arguments passed to or from other methods.

Details

seek with where = NA returns the current byte offset of a connection (from the beginning), and
with a non-missing where argument the connection is re-positioned (if possible) to the specified
position. isSeekable returns whether the connection in principle supports seek: currently only
(possibly gz-compressed) file connections do.

where is stored as a real but should represent an integer: non-integer values are likely to be trun-
cated. Note that the possible values can exceed the largest representable number in an R integer
on 64-bit builds, and on some 32-bit builds.

File connections can be open for both writing/appending, in which case R keeps separate positions
for reading and writing. Which seek refers to can be set by its rw argument: the default is the last
mode (reading or writing) which was used. Most files are only opened for reading or writing and so
default to that state. If a file is open for both reading and writing but has not been used, the default
is to give the reading position (0).

The initial file position for reading is always at the beginning. The initial position for writing is at
the beginning of the file for modes "r+" and "r+b", otherwise at the end of the file. Some platforms
only allow writing at the end of the file in the append modes. (The reported write position for a file
opened in an append mode will typically be unreliable until the file has been written to.)

gzfile connections support seek with a number of limitations, using the file position of the un-
compressed file. They do not support origin = "end". When writing, seeking is only possible
forwards: when reading seeking backwards is supported by rewinding the file and re-reading from its start.

If seek is called with a non-NA value of where, any pushback on a text-mode connection is discarded.

truncate truncates a file opened for writing at its current position. It works only for file connections, and is not implemented on all platforms: on others (including Windows) it will not work for large (> 2Gb) files.

None of these should be expected to work on text-mode connections with re-encoding selected.

Value

seek returns the current position (before any move), as a (numeric) byte offset from the origin, if relevant, or 0 if not. Note that the position can exceed the largest representable number in an R integer on 64-bit builds, and on some 32-bit builds.

truncate returns NULL: it stops with an error if it fails (or is not implemented).

isSeekable returns a logical value, whether the connection supports seek.

Warning

Use of seek on Windows is discouraged. We have found so many errors in the Windows implementation of file positioning that users are advised to use it only at their own risk, and asked not to waste the R developers’ time with bug reports on Windows’ deficiencies.

seq

Sequence Generation

Description

Generate regular sequences. seq is a standard generic with a default method. seq.int is a primitive which can be much faster but has a few restrictions. seq_along and seq_len are very fast primitives for two common cases.

Usage

seq(...)

## Default S3 method:
seq(from = 1, to = 1, by = ((to - from)/(length.out - 1)),
   length.out = NULL, along.with = NULL, ...)

seq.int(from, to, by, length.out, along.with, ...)

seq_along(along.with)
seq_len(length.out)
Arguments

... arguments passed to or from methods.

from, to the starting and (maximal) end values of the sequence. Of length 1 unless just from is supplied as an unnamed argument.

by number: increment of the sequence.

length.out desired length of the sequence. A non-negative number, which for seq and seq.int will be rounded up if fractional.

along.with take the length from the length of this argument.

Details

Numerical inputs should all be finite (that is, not infinite, NaN or NA).

The interpretation of the unnamed arguments of seq and seq.int is not standard, and it is recommended always to name the arguments when programming.

seq is generic, and only the default method is described here. Note that it dispatches on the class of the first argument irrespective of argument names. This can have unintended consequences if it is called with just one argument intending this to be taken as along.with: it is much better to use seq_along in that case.

seq.int is an internal generic which dispatches on methods for "seq" based on the class of the first supplied argument (before argument matching).

Typical usages are

seq(from, to)
seq(from, to, by = )
seq(from, to, length.out = )
seq(along.with = )
seq(from)
seq(length.out = )

The first form generates the sequence from, from+/-1, ..., to (identical to from:to).

The second form generates from, from+by, ..., up to the sequence value less than or equal to to. Specifying to - from and by of opposite signs is an error. Note that the computed final value can go just beyond to to allow for rounding error, but is truncated to to. (‘Just beyond’ is by up to 10^{-10} times abs(from - to).)

The third generates a sequence of length.out equally spaced values from from to to. (length.out is usually abbreviated to length or len, and seq_len is much faster.)

The fourth form generates the integer sequence 1, 2, ..., length(along.with). (along.with is usually abbreviated to along, and seq_along is much faster.)

The fifth form generates the sequence 1, 2, ..., length(from) (as if argument along.with had been specified), unless the argument is numeric of length 1 when it is interpreted as 1:from (even for seq(θ) for compatibility with S). Using either seq_along or seq_len is much preferred (unless strict S compatibility is essential).

The final form generates the integer sequence 1, 2, ..., length.out unless length.out = 0, when it generates integer(θ).

Very small sequences (with from - to of the order of 10^{-14} times the larger of the ends) will return from.
For seq (only), up to two of from, to and by can be supplied as complex values provided
length.out or along.with is specified. More generally, the default method of seq will handle
classed objects with methods for the Math, Ops and Summary group generics.

seq.int, seq_along and seq_len are primitive.

Value

seq.int and the default method of seq for numeric arguments return a vector of type "integer"
or "double": programmers should not rely on which.
seq_along and seq_len return an integer vector, unless it is a long vector when it will be double.

References

Brooks/Cole.

See Also

The methods seq.Date and seq.POSIXt.

Examples

seq(0, 1, length.out = 11)
seq(stats::rnorm(20)) # effectively 'along'
seq(l, 9, by = 2) # matches 'end'
seq(l, 9, by = pi) # stays below 'end'
seq(l, 6, by = 3)
seq(1.575, 5.125, by = 0.05)
seq(17) # same as 1:17, or even better seq_len(17)

seq.Date

Generate Regular Sequences of Dates

Description

The method for seq for objects of class "Date" representing calendar dates.

Usage

## S3 method for class 'Date'
seq(from, to, by, length.out = NULL, along.with = NULL, ...)

Arguments

from       starting date. Required
to         end date. Optional.
by          increment of the sequence. Optional. See 'Details'.
length.out integer, optional. Desired length of the sequence.
along.with take the length from the length of this argument.
...         arguments passed to or from other methods.
Details

by can be specified in several ways.

- A number, taken to be in days.
- A object of class `difftime`
- A character string, containing one of "day", "week", "month", "quarter" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s". See `seq.POSIXt` for the details of "month".

Value

A vector of class "Date".

See Also

`Date`

Examples

```r
## first days of years
seq(as.Date("1910/1/1"), as.Date("1999/1/1"), "years")
## by month
seq(as.Date("2000/1/1"), by = "month", length.out = 12)
## quarters
seq(as.Date("2000/1/1"), as.Date("2003/1/1"), by = "quarter")
## find all 7th of the month between two dates, the last being a 7th.
st <- as.Date("1998-12-17")
end <- as.Date("2000-1-7")
ll <- seq(end, st, by = "-1 month")
rev(ll[ll > st & ll < end])
```

`seq.POSIXt`  
Generate Regular Sequences of Times

Description

The method for `seq` for date-time classes.

Usage

```r
## S3 method for class 'POSIXt'
seq(from, to, by, length.out = NULL, along.with = NULL, ...)
```

Arguments

- `from`: starting date. Required.
- `to`: end date. Optional.
- `by`: increment of the sequence. Optional. See ‘Details’.
- `length.out`: integer, optional. Desired length of the sequence.
- `along.with`: take the length from the length of this argument.
- `...`: arguments passed to or from other methods.
Details

by can be specified in several ways.

- A number, taken to be in seconds.
- A object of class `difftime`
- A character string, containing one of "sec", "min", "hour", "day", "DSTday", "week", "month", "quarter" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s".

The difference between "day" and "DSTday" is that the former ignores changes to/from daylight savings time and the latter takes the same clock time each day. ("week" ignores DST (it is a period of 144 hours), but "7 DSTdays") can be used as an alternative. "month" and "year" allow for DST.

The time zone of the result is taken from from: remember that GMT means UTC (and not the time zone of Greenwich, England) and so does not have daylight savings time.

Using "month" first advances the month without changing the day: if this results in an invalid day of the month, it is counted forward into the next month: see the examples.

Value

A vector of class "POSIXct".

See Also

`DateTimeClasses`

Examples

```r
## first days of years
seq(ISOdate(1910,1,1), ISOdate(1999,1,1), "years")
## by month
seq(ISOdate(2000,1,1), by = "month", length.out = 12)
seq(ISOdate(2000,1,31), by = "month", length.out = 4)
## quarters
seq(ISOdate(1990,1,1), ISOdate(2000,1,1), by = "quarter") # or "3 months"
## days vs DSTdays: use c() to lose the time zone.
seq(c(ISOdate(2000,3,20)), by = "day", length.out = 10)
seq(c(ISOdate(2000,3,20)), by = "DSTday", length.out = 10)
seq(c(ISOdate(2000,3,20)), by = "7 DSTdays", length.out = 4)
```

Sequence (`sequence`)

Create A Vector of Sequences

Description

For each element of `nvec` the sequence `seq_len(nvec[i])` is created. These are concatenated and the result returned.

Usage

`sequence(nvec)`
Arguments

- **nvec**: a non-negative integer vector each element of which specifies the end point of a sequence.

Details

Earlier versions of `sequence` used to work for 0 or negative inputs as `seq(x) == 1:x`.

Note that `sequence <- function(nvec) unlist(lapply(nvec, seq_len))` and it mainly exists in reverence to the very early history of R.

See Also

- `gl`, `seq`, `rep`.

Examples

```r
sequence(c(3, 2)) # the concatenated sequences 1:3 and 1:2.
#> [1] 1 2 3 1 2
```

---

### serialize

**Simple Serialization Interface**

#### Description

A simple low-level interface for serializing to connections.

#### Usage

```r
serialize(object, connection, ascii, xdr = TRUE, version = NULL, refhook = NULL)
```

```r
unserialize(connection, refhook = NULL)
```

#### Arguments

- **object**: R object to serialize.
- **connection**: an open connection or (for `serialize`) NULL or (for `unserialize`) a raw vector (see ‘Details’).
- **ascii**: a logical. If TRUE or NA, an ASCII representation is written; otherwise (default) a binary one. See also the comments in the help for `save`.
- **xdr**: a logical: if a binary representation is used, should a big-endian one (XDR) be used?
- **version**: the workspace format version to use. NULL specifies the current default version (2). Versions prior to 2 are not supported, so this will only be relevant when there are later versions.
- **refhook**: a hook function for handling reference objects.
Details

The function `serialize` serializes object to the specified connection. If `connection` is `NULL` then object is serialized to a raw vector, which is returned as the result of `serialize`.

Sharing of reference objects is preserved within the object but not across separate calls to `serialize`.

`unserialize` reads an object (as written by `serialize`) from `connection` or a raw vector.

The `refhook` functions can be used to customize handling of non-system reference objects (all external pointers and weak references, and all environments other than namespace and package environments and `.GlobalEnv`). The hook function for `serialize` should return a character vector for references it wants to handle; otherwise it should return `NULL`. The hook for `unserialize` will be called with character vectors supplied to `serialize` and should return an appropriate object.

For a text-mode connection, the default value of `ascii` is set to `TRUE`: only ASCII representations can be written to text-mode connections and attempting to use `ascii = FALSE` will throw an error.

The format consists of a single line followed by the data: the first line contains a single character: `X` for binary serialization and `A` for ASCII serialization, followed by a new line. (The format used is identical to that used by `readRDS`.)

As almost all systems in current use are little-endian, `xdr = FALSE` can be used to avoid byte-shuffling at both ends when transferring data from one little-endian machine to another (or between processes on the same machine). Depending on the system, this can speed up serialization and unserialization by a factor of up to 3x.

Value

For `serialize`, `NULL` unless `connection = NULL`, when the result is returned in a raw vector.

For `unserialize` an R object.

Warning

These functions have provided a stable interface since R 2.4.0 (when the storage of serialized objects was changed from character to raw vectors). However, the serialization format may change in future versions of R, so this interface should not be used for long-term storage of R objects.

On 32-bit platforms a raw vector is limited to $2^{31} - 1$ bytes, but R objects can exceed this and their serializations will normally be larger than the objects.

See Also

`saveRDS` for a more convenient interface to serialize an object to a file or connection.

`save` and `load` to serialize and restore one or more named objects.

The ‘R Internals’ manual for details of the format used.

Examples

```r
x <- serialize(list(1,2,3), NULL)
unserialize(x)
```

## see also the examples for `saveRDS`
set operations

**Description**
Performs set union, intersection, (asymmetric!) difference, equality and membership on two vectors.

**Usage**
- `union(x, y)`
- `intersect(x, y)`
- `setdiff(x, y)`
- `setequal(x, y)`
- `is.element(el, set)`

**Arguments**
- `x, y, el, set`: vectors (of the same mode) containing a sequence of items (conceptually) with no duplicated values.

**Details**
Each of `union`, `intersect`, `setdiff` and `setequal` will discard any duplicated values in the arguments, and they apply `as.vector` to their arguments (and so in particular coerce factors to character vectors).

- `is.element(x, y)` is identical to `x %in% y`.

**Value**
A vector of the same mode as `x` or `y` for `setdiff` and `intersect`, respectively, and of a common mode for `union`.

- A logical scalar for `setequal` and a logical of the same length as `x` for `is.element`.

**See Also**
- `%in%`
- `plotmath` for the use of `union` and `intersect` in plot annotation.

**Examples**
```r
(x <- c(sort(sample(1:20, 9)), NA))
y <- c(sort(sample(3:23, 7)), NA)
union(x, y)
intersect(x, y)
setdiff(x, y)
setdiff(y, x)
setequal(x, y)

## True for all possible x & y:
setequal(union(x, y),
```
c(setdiff(x, y), intersect(x, y), setdiff(y, x))

is.element(x, y) # length 10
is.element(y, x) # length 8

setTimeLimit  

Description

Functions to set CPU and/or elapsed time limits for top-level computations or the current session.

Usage

setTimeLimit(cpu = Inf, elapsed = Inf, transient = FALSE)

setSessionTimeLimit(cpu = Inf, elapsed = Inf)

Arguments

cpu, elapsed  double (of length one). Set a limit on the total or elapsed cpu time in seconds, respectively.
transient  logical. If TRUE, the limits apply only to the rest of the current computation.

Details

setTimeLimit sets limits which apply to each top-level computation, that is a command line (including any continuation lines) entered at the console or from a file. If it is called from within a computation the limits apply to the rest of the computation and (unless transient = TRUE) to subsequent top-level computations.

setSessionTimeLimit sets limits for the rest of the session. Once a session limit is reached it is reset to Inf.

Setting any limit has a small overhead – well under 1% on the systems measured.

Time limits are checked whenever a user interrupt could occur. This will happen frequently in R code and during Sys.sleep, but only at points in compiled C and Fortran code identified by the code author.

‘Total cpu time’ includes that used by child processes where the latter is reported.

showConnections  

Description

Display aspects of connections.
showConnections

Usage

showConnections(all = FALSE)
getConnection(what)
closeAllConnections()

stdin()
stdout()
stderr()

isatty(con)

Arguments

all logical: if true all connections, including closed ones and the standard ones are displayed. If false only open user-created connections are included.

what integer: a row number of the table given by showConnections.

con a connection.

Details

stdin(), stdout() and stderr() are standard connections corresponding to input, output and error on the console respectively (and not necessarily to file streams). They are text-mode connections of class "terminal" which cannot be opened or closed, and are read-only, write-only and write-only respectively. The stdout() and stderr() connections can be re-directed by sink (and in some circumstances the output from stdout() can be split: see the help page).

The encoding for stdin() when redirected can be set by the command-line flag '--encoding'.

showConnections returns a matrix of information. If a connection object has been lost or forgotten, getConnection will take a row number from the table and return a connection object for that connection, which can be used to close the connection, for example. However, if there is no R level object referring to the connection it will be closed automatically at the next garbage collection (except for gzcon connections).

closeAllConnections closes (and destroys) all user connections, restoring all sink diversions as it does so.

isatty returns true if the connection is one of the class "terminal" connections and it is apparently connected to a terminal, otherwise false. This may not be reliable in embedded applications, including GUI consoles.

Value

stdin(), stdout() and stderr() return connection objects.

showConnections returns a character matrix of information with a row for each connection, by default only for open non-standard connections.

getConnection returns a connection object, or NULL.

Note

stdin() refers to the 'console' and not to the C-level 'stdin' of the process. The distinction matters in GUI consoles (which may not have an active 'stdin', and if they do it may not be connected to console input), and also in embedded applications. If you want access to the C-level file stream 'stdin', use file("stdin").
When R is reading a script from a file, the file is the ‘console’: this is traditional usage to allow in-line data (see ‘An Introduction to R’ for an example).

Examples

showConnections(all = TRUE)
## Not run:
textConnection(letters)
# oops, I forgot to record that one
showConnections()
# class   description      mode text isOpen can.read can.write
#3      "letters" "textConnection" "r" "text" "opened" "yes"   "no"
mycon <- getConnection(3)
## End(Not run)
c(isatty(stdin())), isatty(stdout()), isatty(stderr()))

shQuote

Quote Strings for Use in OS Shells

Description

Quote a string to be passed to an operating system shell.

Usage

shQuote(string, type = c("sh", "csh", "cmd", "cmd2"))

Arguments

string  a character vector, usually of length one.

type     character: the type of shell quoting. Partial matching is supported. "cmd" and "cmd2" refer to the Windows shell. "cmd" is the default under Windows.

Details

The default type of quoting supported under Unix-alikes is that for the Bourne shell sh. If the string does not contain single quotes, we can just surround it with single quotes. Otherwise, the string is surrounded in double quotes, which suppresses all special meanings of metacharacters except dollar, backquote and backslash, so these (and of course double quote) are preceded by backslash. This type of quoting is also appropriate for bash, ksh and zsh.

The other type of quoting is for the C-shell (csh and tcsh). Once again, if the string does not contain single quotes, we can just surround it with single quotes. If it does contain single quotes, we can use double quotes provided it does not contain dollar or backquote (and we need to escape backslash, exclamation mark and double quote). As a last resort, we need to split the string into pieces not containing single quotes and surround each with single quotes, and the single quotes with double quotes.
In Windows, command line interpretation is done by the application as well as the shell. It may depend on the compiler used: Microsoft’s rules for the C run-time are given at https://msdn.microsoft.com/library/ms880421. It may depend on the whim of the programmer of the application: check its documentation. The type = "cmd" quoting surrounds the string by double quotes and escapes internal double quotes by a backslash. As Windows path names cannot contain double quotes, this makes shQuote safe for use with many applications when used with system or system2. The Windows cmd.exe shell (used by default with shell) uses type = "cmd2" quoting: special characters are prefixed with "^". In some cases, two types of quoting should be used: first for the application, and then type = "cmd2" for cmd.exe. See the examples below.

References

Discussion in PR#16636.

See Also

Quotes for quoting R code.
sQuote for quoting English text.

Examples

test <- "abc$def'gh`i\j"
cat(shQuote(test), "\n")
## Not run: system(paste("echo", shQuote(test)))
test <- "don’t do it!"
cat(shQuote(test), "\n")

tryit <- paste("use the", sQuote("-c"), "switch\nlike this")
cat(shQuote(tryit), "\n")
## Not run: system(paste("echo", shQuote(tryit)))
cat(shQuote(tryit, type = "csh"), "\n")

## Windows-only example, assuming cmd.exe:
perlcmd <- "print "Hello World\n"
## Not run:
shell(shQuote(paste("perl -e",

  shQuote(perlcmd, type = "cmd"),

  type = "cmd2")))

## End(Not run)

---

**sign**  
*Sign Function*

**Description**

sign returns a vector with the signs of the corresponding elements of x (the sign of a real number is 1, 0, or −1 if the number is positive, zero, or negative, respectively).

Note that sign does not operate on complex vectors.
Usage

    sign(x)

Arguments

    x  a numeric vector

Details

    This is an internal generic primitive function: methods can be defined for it directly or via the Math group generic.

See Also

    abs

Examples

    sign(pi)  # == 1
    sign(-2:3) # -1 -1 0 1 1 1

Signals

Interrupting Execution of R

Description

    On receiving SIGUSR1 R will save the workspace and quit. SIGUSR2 has the same result except that the .Last function and on.exit expressions will not be called.

Usage

    kill -USR1 pid
    kill -USR2 pid

Arguments

    pid  The process ID of the R process.

Details

    The commands history will also be saved if would be at normal termination.
    This is not available on Windows, and possibly on other OSes which do not support these signals.

Warning

    It is possible that one or more R objects will be undergoing modification at the time the signal is sent. These objects could be saved in a corrupted form.

See Also

    Sys.getpid to report the process ID for future use.
sink  

Send R Output to a File

Description

sink diverts R output to a connection (and stops such diversions).
sink.number() reports how many diversions are in use.
sink.number(type = "message") reports the number of the connection currently being used for error messages.

Usage

sink(file = NULL, append = FALSE, type = c("output", "message"),
    split = FALSE)

sink.number(type = c("output", "message"))

Arguments

file a writable connection or a character string naming the file to write to, or NULL to stop sink-ing.
append logical. If TRUE, output will be appended to file; otherwise, it will overwrite the contents of file.
type character string. Either the output stream or the messages stream. The name will be partially matched so can be abbreviated.
split logical: if TRUE, output will be sent to the new sink and to the current output stream, like the Unix program tee.

Details

sink diverts R output to a connection (and must be used again to finish such a diversion, see below!). If file is a character string, a file connection with that name will be established for the duration of the diversion.

Normal R output (to connection stdout) is diverted by the default type = "output". Only prompts and (most) messages continue to appear on the console. Messages sent to stderr() (including those from message, warning and stop) can be diverted by sink(type = "message") (see below).
sink() or sink(file = NULL) ends the last diversion (of the specified type). There is a stack of diversions for normal output, so output reverts to the previous diversion (if there was one). The stack is of up to 21 connections (20 diversions).

If file is a connection it will be opened if necessary (in "wt" mode) and closed once it is removed from the stack of diversions.

split = TRUE only splits R output (via Rprintf) and the default output from writelines: it does not split all output that might be sent to stdout().

Sink-ing the messages stream should be done only with great care. For that stream file must be an already open connection, and there is no stack of connections.

If file is a character string, the file will be opened using the current encoding. If you want a different encoding (e.g., to represent strings which have been stored in UTF-8), use a file connection — but some ways to produce R output will already have converted such strings to the current encoding.
Value

sink returns NULL.
For sink.number() the number (0, 1, 2, ... ) of diversions of output in place.
For sink.number("message") the connection number used for messages, 2 if no diversion has been used.

Warning

Do not use a connection that is open for sink for any other purpose. The software will stop you closing one such inadvertently.
Do not sink the messages stream unless you understand the source code implementing it and hence the pitfalls.

References

See Also

capture.output

Examples

sink("sink-examp.txt")
i <- 1:10
outer(i, i, "+")
sink()

## capture all the output to a file.
zz <- file("all.Rout", open = "wt")
sink(zz)
sink(zz, type = "message")
try(log("a"))
## revert output back to the console -- only then access the file!
sink(type = "message")
sink()
file.show("all.Rout")
Arguments

- **x**: an array. If `x` has no dimension attribute, it is considered a one-dimensional array.
- **MARGIN**: an integer giving the dimension number to slice by.

Value

An integer array `y` with dimensions corresponding to those of `x` such that all elements of slice number `i` with respect to dimension `MARGIN` have value `i`.

See Also

- `row` and `col` for determining row and column indexes; in fact, these are special cases of `slice.index` corresponding to `MARGIN` equal to 1 and 2, respectively when `x` is a matrix.

Examples

```r
x <- array(1:24, c(2, 3, 4))
slice.index(x, 2)
```

---

**slotOp**

*Extract or Replace A Slot*

Description

Extract or replace the contents of a slot in a object with a formal (S4) class structure.

Usage

```r
object@name
object@name <- value
```

Arguments

- **object**: An object from a formally defined (S4) class.
- **name**: The character-string name of the slot, quoted or not. Must be the name of a slot in the definition of the class of `object`.
- **value**: A replacement value for the slot, which must be from a class compatible with the class defined for this slot in the definition of the class of `object`.

Details

These operators support the formal classes of package `methods`, and are enabled only when package `methods` is loaded (as per default). See `slot` for further details, in particular for the differences between `slot()` and the `@` operator.

It is checked that `object` is an S4 object (see `isS4`), and it is an error to attempt to use `@` on any other object. (There is an exception for name `.Data` for internal use only.) The replacement operator checks that the slot already exists on the object (which it should if the object is really from the class it claims to be).

These are internal generic operators: see `InternalMethods`. 
socketSelect

Wait on Socket Connections

Description

Waits for the first of several socket connections to become available.

Usage

socketSelect(socklist, write = FALSE, timeout = NULL)

Arguments

socklist: list of open socket connections
write: logical. If TRUE wait for corresponding socket to become available for writing; otherwise wait for it to become available for reading.
timeout: numeric or NULL. Time in seconds to wait for a socket to become available; NULL means wait indefinitely.

Details

The values in write are recycled if necessary to make up a logical vector the same length as socklist. Socket connections can appear more than once in socklist; this can be useful if you want to determine whether a socket is available for reading or writing.

Value

Logical the same length as socklist indicating whether the corresponding socket connection is available for output or input, depending on the corresponding value of write.

Examples

## Not run:
## test whether socket connection s is available for writing or reading
socketSelect(list(s, s), c(TRUE, FALSE), timeout = 0)

## End(Not run)
solve

Solve a System of Equations

Description

This generic function solves the equation $a \times x = b$ for $x$, where $b$ can be either a vector or a matrix.

Usage

solve(a, b, ...)

## Default S3 method:
solve(a, b, tol, LINPACK = FALSE, ...)

Arguments

- **a**: a square numeric or complex matrix containing the coefficients of the linear system. Logical matrices are coerced to numeric.
- **b**: a numeric or complex vector or matrix giving the right-hand side(s) of the linear system. If missing, $b$ is taken to be an identity matrix and solve will return the inverse of $a$.
- **tol**: the tolerance for detecting linear dependencies in the columns of $a$. The default is `.Machine$double.eps`. Not currently used with complex matrices $a$.
- **LINPACK**: logical. Defunct and ignored.
- **...**: further arguments passed to or from other methods

Details

- a or $b$ can be complex, but this uses double complex arithmetic which might not be available on all platforms.
- The row and column names of the result are taken from the column names of $a$ and of $b$ respectively. If $b$ is missing the column names of the result are the row names of $a$. No check is made that the column names of $a$ and the row names of $b$ are equal.
- For back-compatibility $a$ can be a (real) QR decomposition, although `qr.solve` should be called in that case. `qr.solve` can handle non-square systems.
- Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code; these can only be interpreted by detailed study of the FORTRAN code.

Source

The default method is an interface to the LAPACK routines DGESV and ZGESV.
LAPACK is from http://www.netlib.org/lapack.

Examples

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
h8 <- hilbert(8); h8
sh8 <- solve(h8)
round(sh8 %*% h8, 3)

A <- hilbert(4)
A[] <- as.complex(A)
## might not be supported on all platforms
try(solve(A))

sort

Sorting or Ordering Vectors

Description

Sort (or order) a vector or factor (partially) into ascending or descending order. For ordering along more than one variable, e.g., for sorting data frames, see `order`.

Usage

sort(x, decreasing = FALSE, ...)

## Default S3 method:
sort(x, decreasing = FALSE, na.last = NA, ...)

sort.int(x, partial = NULL, na.last = NA, decreasing = FALSE,
          method = c("auto", "shell", "quick", "radix"), index.return = FALSE)

Arguments

x        for sort an R object with a class or a numeric, complex, character or logical vector. For sort.int, a numeric, complex, character or logical vector, or a factor.
decreasing logical. Should the sort be increasing or decreasing? For the "radix" method, this can be a vector of length equal to the number of arguments in .... For the other methods, it must be length one. Not available for partial sorting.
...       arguments to be passed to or from methods or (for the default methods and objects without a class) to sort.int.
na.last   for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed.
partial   NULL or a vector of indices for partial sorting.
method    character string specifying the algorithm used. Not available for partial sorting. Can be abbreviated.
index.return logical indicating if the ordering index vector should be returned as well. Supported by method == "radix" for any na.last mode and data type, and the other methods when na.last = NA (the default) and fully sorting non-factors.
sort is a generic function for which methods can be written, and \texttt{sort.int} is the internal method which is compatible with \texttt{S} if only the first three arguments are used.

The default \texttt{sort} method makes use of \texttt{order} for classed objects, which in turn makes use of the generic function \texttt{xtfrm} (and can be slow unless a \texttt{xtfrm} method has been defined or \texttt{is.numeric}(x) is true).

Complex values are sorted first by the real part, then the imaginary part.

The \texttt{"auto"} method selects \texttt{"radix"} for short (less than $2^{31}$ elements) numeric vectors, integer vectors, logical vectors and factors; otherwise, \texttt{"shell"}.

Except for method \texttt{"radix"}, the sort order for character vectors will depend on the collating sequence of the locale in use: see \texttt{Comparison}. The sort order for factors is the order of their levels (which is particularly appropriate for ordered factors).

If \texttt{partial} is not \texttt{NULL}, it is taken to contain indices of elements of the result which are to be placed in their correct positions in the sorted array by partial sorting. For each of the result values in a specified position, any values smaller than that one are guaranteed to have a smaller index in the sorted array and any values which are greater are guaranteed to have a bigger index in the sorted array. (This is included for efficiency, and many of the options are not available for partial sorting. It is only substantially more efficient if \texttt{partial} has a handful of elements, and a full sort is done (a Quicksort if possible) if there are more than 10.) Names are discarded for partial sorting.

Method \texttt{"shell"} uses Shellsort (an $O(n^{4/3})$ variant from Sedgewick (1986)). If \texttt{x} has names a stable modification is used, so ties are not reordered. (This only matters if names are present.) Method \texttt{"quick"} uses Singleton (1969)'s implementation of Hoare's Quicksort method and is only available when \texttt{x} is numeric (double or integer) and \texttt{partial} is \texttt{NULL}. (For other types of \texttt{x} Shellsort is used, silently.) It is normally somewhat faster than Shellsort (perhaps 50\% faster on vectors of length a million and twice as fast at a billion) but has poor performance in the rare worst case. (Peto's modification using a pseudo-random midpoint is used to make the worst case rarer.) This is not a stable sort, and ties may be reordered.

Method \texttt{"radix"} relies on simple hashing to scale time linearly with the input size, i.e., its asymptotic time complexity is $O(n)$. The specific variant and its implementation originated from the \texttt{data.table} package and are due to Matt Dowle and Arun Srinivasan. For small inputs (< 200), the implementation uses an insertion sort ($O(n^2)$) that operates in-place to avoid the allocation overhead of the radix sort. For integer vectors of range less than 100,000, it switches to a simpler and faster linear time counting sort. In all cases, the sort is stable; the order of ties is preserved. It is the default method for integer vectors and factors.

The \texttt{"radix"} method generally outperforms the other methods, especially for character vectors and small integers. Compared to quick sort, it is slightly faster for vectors with large integer or real values (but unlike quick sort, radix is stable and supports all \texttt{na.last} options). The implementation is orders of magnitude faster than shell sort for character vectors, in part thanks to clever use of the internal \texttt{CHARSXP} table.

However, there are some caveats with the radix sort:

- If \texttt{x} is a character vector, all elements must share the same encoding. Only UTF-8 (including ASCII) and Latin-1 encodings are supported. Collation always follows the "C" locale.
- Long vectors (with more than $2^{32}$ elements) and \texttt{complex} vectors are not supported yet.

Value

For \texttt{sort}, the result depends on the S3 method which is dispatched. If \texttt{x} does not have a class \texttt{sort.int} is used and it description applies. For classed objects which do not have a specific
method the default method will be used and is equivalent to \texttt{x[order(x, ...)]:} this depends on the class having a suitable method for \texttt{[} and also that \texttt{order} will work, which requires a \texttt{xtfrm} method.

For \texttt{sort.int} the value is the sorted vector unless \texttt{index.return} is true, when the result is a list with components named \texttt{x} and \texttt{ix} containing the sorted numbers and the ordering index vector. In the latter case, if \texttt{method == "quick"} ties may be reversed in the ordering (unlike \texttt{sort.list}) as quicksort is not stable. For \texttt{method == "radix"}, \texttt{index.return} is supported for all \texttt{na.last} modes. The other methods only support \texttt{index.return} when \texttt{na.last} is \texttt{NA}. The index vector refers to element numbers \textit{after removal of} \texttt{NA}s: see \texttt{order} if you want the original element numbers.

All attributes are removed from the return value (see Becker et al., 1988, p.146) except names, which are sorted. (If \texttt{partial} is specified even the names are removed.) Note that this means that the returned value has no class, except for factors and ordered factors (which are treated specially and whose result is transformed back to the original class).

Sim <- 20
```
rep <- 1000 # << adjust to your CPU
c1 <- c2 <- numeric(Sim)
for(is in seq_len(Sim)) {
  x <- rnorm(N)
  c1[is] <- system.time(for(i in 1:rep) sort(x, method = "shell"))[1]
  c2[is] <- system.time(for(i in 1:rep) sort(x, method = "quick"))[1]
  stopifnot(sort(x, method = "shell") == sort(x, method = "quick"))
}
rbind(ShellSort = c1, QuickSort = c2)
cat("Speedup factor of quick sort:
")
summary({qq <- c1 / c2; qq[is.finite(qq)])

## A larger test
x <- rnorm(1e7)
system.time(x1 <- sort(x, method = "shell"))
system.time(x2 <- sort(x, method = "quick"))
system.time(x3 <- sort(x, method = "radix"))
stopifnot(identical(x1, x2))
stopifnot(identical(x1, x3))

## End(Not run)

source  
---

Read R Code from a File, a Connection or Expressions

Description

source causes R to accept its input from the named file or URL or connection or expressions directly. Input is read and parsed from that file until the end of the file is reached, then the parsed expressions are evaluated sequentially in the chosen environment.

withAutoprint(exprs) is a wrapper for source(exprs = exprs, ...) with different defaults. Its main purpose is to evaluate and auto-print expressions as if in a toplevel context, e.g., as in the R console.

Usage

source(file, local = FALSE, echo = verbose, print.eval = echo,
  exprs, spaced = use_file,
  verbose = getOption("verbose"),
  prompt.echo = getOption("prompt"),
  max.deparse.length = 150, width.cutoff = 60L,
  deparseCtrl = "showAttributes",
  chdir = FALSE,
  encoding = getOption("encoding"),
  continue.echo = getOption("continue"),
  skip.echo = 0, keep.source = getOption("keep.source"))

withAutoprint(exprs, evaluated = FALSE, local = parent.frame(),
  print. = TRUE, echo = TRUE, max.deparse.length = Inf,
  width.cutoff = max(20, getOption("width")),
  deparseCtrl = c("keepInteger", "showAttributes", "keepNA"),
  ...)

---
Arguments

file a connection or a character string giving the pathname of the file or URL to read from. "" indicates the connection stdin().

local TRUE, FALSE or an environment, determining where the parsed expressions are evaluated. FALSE (the default) corresponds to the user’s workspace (the global environment) and TRUE to the environment from which source is called.

echo logical; if TRUE, each expression is printed after parsing, before evaluation.

print.eval, print.logical; if TRUE, the result of eval(i) is printed for each expression i; defaults to the value of echo.

exprs for source() and withAutoprint(*, evaluated=TRUE): instead of specifying file, an expression, call, or list of call’s, but not an unevaluated “expression”.

for withAutoprint() (with default evaluated=FALSE): one or more unevaluated “expressions”.

evaluated logical indicating that exprs is passed to source(exprs = *) and hence must be evaluated, i.e., a formal expression, call or list of calls.

spaced logical indicating if newline (hence empty line) should be printed before each expression (when echo = TRUE).

verbose if TRUE, more diagnostics (than just echo = TRUE) are printed during parsing and evaluation of input, including extra info for each expression.

prompt.echo character; gives the prompt to be used if echo = TRUE.

max.deparse.length integer; is used only if echo is TRUE and gives the maximal number of characters output for the deparse of a single expression.

width.cutoff integer, passed to deparse() which is used (only) when there are no source references.

deparseCtrl character vector, passed as control to deparse(), see also .deparseOpts. In R version <= 3.3.x, this was hardcoded to "showAttributes", which is the default currently; deparseCtrl = "all" may be preferable, when strict back compatibility is not of importance.

chdir logical; if TRUE and file is a pathname, the R working directory is temporarily changed to the directory containing file for evaluating.

encoding character vector. The encoding(s) to be assumed when file is a character string: see file. A possible value is "unknown" when the encoding is guessed: see the ‘Encodings’ section.

continue.echo character; gives the prompt to use on continuation lines if echo = TRUE.

skip.echo integer; how many comment lines at the start of the file to skip if echo = TRUE.

keep.source logical: should the source formatting be retained when echoing expressions, if possible?

... (for withAutoprint():) further (non-file related) arguments to be passed to source(.).

Details

Note that running code via source differs in a few respects from entering it at the R command line. Since expressions are not executed at the top level, auto-printing is not done. So you will need
to include explicit `print` calls for things you want to be printed (and remember that this includes plotting by `lattice`, FAQ Q7.22). Since the complete file is parsed before any of it is run, syntax errors result in none of the code being run. If an error occurs in running a syntactically correct script, anything assigned into the workspace by code that has been run will be kept (just as from the command line), but diagnostic information such as `traceback()` will contain additional calls to `withVisible`.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic Mac OS) and map this to newline. The final line can be incomplete, that is missing the final end-of-line marker.

If `keep.source` is true (the default in interactive use), the source of functions is kept so they can be listed exactly as input.

Unlike input from a console, lines in the file or on a connection can contain an unlimited number of characters.

When `skip.echo > 0`, that many comment lines at the start of the file will not be echoed. This does not affect the execution of the code at all. If there are executable lines within the first `skip.echo` lines, echoing will start with the first of them.

If `echo` is true and a deparsed expression exceeds `max.deparse.length`, that many characters are output followed by `.... [TRUNCATED]`.

### Encodings

By default the input is read and parsed in the current encoding of the R session. This is usually what it required, but occasionally re-encoding is needed, e.g. if a file from a UTF-8-using system is to be read on Windows (or *vice versa*).

The rest of this paragraph applies if `file` is an actual filename or URL (and not "" nor a connection). If `encoding = "unknown"`, an attempt is made to guess the encoding: the result of `localeToCharset()` is used as a guide. If encoding has two or more elements, they are tried in turn until the file/URL can be read without error in the trial encoding. If an actual encoding is specified (rather than the default or "unknown") in a Latin-1 or UTF-8 locale then character strings in the result will be translated to the current encoding and marked as such (see Encoding).

If `file` is a connection (including one specified by "", it is not possible to re-encode the input inside `source`, and so the encoding argument is just used to mark character strings in the parsed input in Latin-1 and UTF-8 locales: see `parse`.

### Examples

```r
someCond <- 7 > 6
## want an if-clause to behave "as top level" wrt auto-printing :
## (all should look "as if on top level", e.g. non-assignments should print:
if(someCond) withAutoprint({
```
x <- 1:12
x-1
(y <- (x-5)*2)
z <- y
z - 10
})

## If you want to source() a bunch of files, something like
## the following may be useful:
sourceDir <- function(path, trace = TRUE, ...) {
  for (nm in list.files(path, pattern = "[.][RrSsQq]$")) {
    if(trace) cat(nm,":"
    source(file.path(path, nm), ...)
    if(trace) cat("\n")
  }
}
suppressWarnings( rm(x,y) ) # remove 'x' or 'y' from global env
withAutoprint({ x <- 1:2; cat("x="x,"\n"; y <- x^2 })
## x and y now exist:
stopifnot(identical(x, 1:2), identical(y, x^2))

withAutoprint({ formals(sourceDir); body(sourceDir) },
               max.dep = 20, verbose = TRUE)

---

Special Functions of Mathematics

Description

Special mathematical functions related to the beta and gamma functions.

Usage

- `beta(a, b)`
- `lbeta(a, b)`
- `gamma(x)`
- `lgamma(x)`
- `psigamma(x, deriv = 0)`
- `digamma(x)`
- `trigamma(x)`
- `choose(n, k)`
- `lchoose(n, k)`
- `factorial(x)`
- `lfactorial(x)`

Arguments

- `a, b` non-negative numeric vectors.
- `x, n` numeric vectors.
- `k, deriv` integer vectors.
Details

The functions `beta` and `lbeta` return the beta function and the natural logarithm of the beta function,

\[ B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a + b)}. \]

The formal definition is

\[ B(a, b) = \int_{0}^{1} t^{a-1}(1-t)^{b-1} dt \]

(Abramowitz and Stegun section 6.2.1, page 258). Note that it is only defined in \( \mathbb{R} \) for non-negative \( a \) and \( b \), and is infinite if either is zero.

The functions `gamma` and `lgamma` return the gamma function \( \Gamma(x) \) and the natural logarithm of the absolute value of the gamma function. The gamma function is defined by (Abramowitz and Stegun section 6.1.1, page 255)

\[ \Gamma(x) = \int_{0}^{\infty} t^{x-1}e^{-t} dt \]

for all real \( x \) except zero and negative integers (when NaN is returned). There will be a warning on possible loss of precision for values which are too close (within about \( 10^{-8} \)) to a negative integer less than ‘-10’.

`factorial(x)` (\( x! \) for non-negative integer \( x \)) is defined to be `gamma(x+1)` and `lfactorial` to be `lgamma(x+1)`.

The functions `digamma` and `trigamma` return the first and second derivatives of the logarithm of the gamma function. `psigamma(x, deriv)` (\( \text{deriv} \geq 0 \)) computes the \( \text{deriv}-\text{th} \) derivative of \( \psi(x) \).

\[ \psi(x) = \frac{d}{dx} \ln \Gamma(x) = \frac{\Gamma'(x)}{\Gamma(x)} \]

\( \psi \) and its derivatives, the `psigamma()` functions, are often called the ‘polygamma’ functions, e.g. in Abramowitz and Stegun (section 6.4.1, page 260); and higher derivatives (\( \text{deriv} = 2:4 \)) have occasionally been called ‘tetragamma’, ‘pentagamma’, and ‘hexagamma’.

The functions `choose` and `lchoose` return binomial coefficients and the logarithms of their absolute values. Note that `choose(n, k)` is defined for all real numbers \( n \) and integer \( k \). For \( k \geq 1 \) it is defined as \( n(n-1)\cdots(n-k+1)/k! \), as 1 for \( k = 0 \) and as 0 for negative \( k \). Non-integer values of \( k \) are rounded to an integer, with a warning.

`choose(*)` uses direct arithmetic (instead of \([l]\gamma\) calls) for small \( k \), for speed and accuracy reasons. Note the function `combn` (package `utils`) for enumeration of all possible combinations.

The gamma, `lgamma`, `digamma` and `trigamma` functions are internal generic primitive functions: methods can be defined for them individually or via the `Math` group generic.

Source

`gamma`, `lgamma`, `beta` and `lbeta` are based on C translations of Fortran subroutines by W. Fullerton of Los Alamos Scientific Laboratory (now available as part of SLATEC).

`digamma`, `trigamma` and `psigamma` are based on

    dy <- diff(y) / dx # finite difference
    der <- which(ch == c("di","tri","tetra","penta")) - 1
    nm2 <- paste0("psigamma(*, deriv = ", der,")")
    nm <- if(der >= 2) nm2 else paste(nm, nm2, sep = " ==")
    y <- psigamma(x, deriv = der)
  } else {
    y <- get(nm)(x)
  }
  plot(x, y, type = "l", main = nm, col = "red")
  abline(h = 0, col = "lightgray")
  if (is.deriv) lines(x[-1], dy, col = "blue", lty = 2)
}
par(mfrow = c(1, 1))

## "Extended" Pascal triangle:
```

```
fN <- function(n) formatC(n, width=2)
for (n in -4:10) {
  cat(fN(n),":", fN(choose(n, k = -2:max(3, n+2))))
  cat("\n")
}
## R code version of choose() [simplistic; warning for k < 0]:
mychoose <- function(r, k)
  ifelse(k <= 0, (k == 0), sapply(k, function(k) prod(r:(r-k+1))) / factorial(k))
k <- -1:6
cbind(k = k, choose(1/2, k), mychoose(1/2, k))
## Binomial theorem for n = 1/2 ;
## sqrt(1+x) = (1+x)^{(1/2)} = sum_{k=0}^Inf choose(1/2, k) * x^k :
k <- 0:10 # 10 is sufficient for ~ 9 digit precision:
sqrt(1.25)
  sum(choose(1/2, k)*.25^k)

---

split  

Divide into Groups and Reassemble

Description

split divides the data in the vector x into the groups defined by f. The replacement forms replace values corresponding to such a division. unsplit reverses the effect of split.

Usage

split(x, f, drop = FALSE, ...)
## Default S3 method:
split(x, f, drop = FALSE, sep = ".", lex.order = FALSE, ...)

split(x, f, drop = FALSE, ...) <- value
unsplit(value, f, drop = FALSE)

Arguments

x  
  vector or data frame containing values to be divided into groups.

f  
  a ‘factor’ in the sense that as.factor(f) defines the grouping, or a list of such factors in which case their interaction is used for the grouping.

drop  
  logical indicating if levels that do not occur should be dropped (if f is a factor or a list).

value  
  a list of vectors or data frames compatible with a splitting of x. Recycling applies if the lengths do not match.

sep  
  character string, passed to interaction in the case where f is a list.

lex.order  
  logical, passed to interaction when f is a list.

...  
  further potential arguments passed to methods.
split and split<- are generic functions with default and data.frame methods. The data frame method can also be used to split a matrix into a list of matrices, and the replacement form likewise, provided they are invoked explicitly.

unsplit works with lists of vectors or data frames (assumed to have compatible structure, as if created by split). It puts elements or rows back in the positions given by f. In the data frame case, row names are obtained by unsplitting the row name vectors from the elements of value.

f is recycled as necessary and if the length of x is not a multiple of the length of f a warning is printed.

Any missing values in f are dropped together with the corresponding values of x.

The default method calls interaction when f is a list. If the levels of the factors contain ‘.’ the factors may not be split as expected, unless sep is set to string not present in the factor levels.

Value

The value returned from split is a list of vectors containing the values for the groups. The components of the list are named by the levels of f (after converting to a factor, or if already a factor and drop = TRUE, dropping unused levels).

The replacement forms return their right hand side. unsplit returns a vector or data frame for which split(x, f) equals value.

Examples

require(stats); require(graphics)

n <- 10; nn <- 100
g <- factor(round(n * runif(n * nn)))
x <- rnorm(n * nn) + sqrt(as.numeric(g))
xg <- split(x, g)
boxplot(xg, col = "lavender", notch = TRUE, varwidth = TRUE)
sapply(xg, length)
sapply(xg, mean)

### Calculate ‘z-scores’ by group (standardize to mean zero, variance one)
z <- unsplit(lapply(split(x, g), scale), g)

# or

zz <- x
split(zz, g) <- lapply(split(x, g), scale)

# and check that the within-group std dev is indeed one
tapply(z, g, sd)
tapply(zz, g, sd)
### data frame variation

## Notice that assignment form is not used since a variable is being added

```r
# g <- airquality$Month
l <- split(airquality, g)
l <- lapply(l, transform, Oz.Z = scale(Ozone))
aq2 <- unsplit(l, g)
head(aq2)
with(aq2, tapply(Oz.Z, Month, sd, na.rm = TRUE))
```

### Split a matrix into a list by columns

```r
ma <- cbind(x = 1:10, y = (-4:5)^2)
split(ma, col(ma))

split(1:10, 1:2)
```

---

**sprintf**

*Use C-style String Formatting Commands*

### Description

A wrapper for the C function `sprintf`, that returns a character vector containing a formatted combination of text and variable values.

### Usage

```r
sprintf(fmt, ...)
gettextf(fmt, ..., domain = NULL)
```

### Arguments

- **fmt**: a character vector of format strings, each of up to 8192 bytes.
- **...**: values to be passed into `fmt`. Only logical, integer, real and character vectors are supported, but some coercion will be done: see the ‘Details’ section. Up to 100.
- **domain**: see `gettext`.

### Details

`sprintf` is a wrapper for the system `sprintf` C-library function. Attempts are made to check that the mode of the values passed match the format supplied, and R’s special values (NA, Inf, -Inf and NaN) are handled correctly.

`gettextf` is a convenience function which provides C-style string formatting with possible translation of the format string.

The arguments (including `fmt`) are recycled if possible a whole number of times to the length of the longest, and then the formatting is done in parallel. Zero-length arguments are allowed and will give a zero-length result. All arguments are evaluated even if unused, and hence some types (e.g., "symbol" or "language", see `typeof`) are not allowed.
The following is abstracted from Kernighan and Ritchie (see References): however the actual implementation will follow the C99 standard and fine details (especially the behaviour under user error) may depend on the platform.

The string \texttt{fmt} contains normal characters, which are passed through to the output string, and also conversion specifications which operate on the arguments provided through \ldots \ldots . The allowed conversion specifications start with a \% and end with one of the letters in the set \texttt{aAdifeEgGosxX}. These letters denote the following types:

\texttt{d, i, o, x, X Integer value, \texttt{o} being octal, \texttt{x} and \texttt{X} being hexadecimal (using the same case for \texttt{a-f} as the code). Numeric variables with exactly integer values will be coerced to integer. Formats \texttt{d} and \texttt{i} can also be used for logical variables, which will be converted to \texttt{0}, \texttt{1} or \texttt{NA}.}

\texttt{f Double precision value, in “fixed point” decimal notation of the form “[\-]mmm.ddd”. The number of decimal places ("d") is specified by the precision: the default is 6; a precision of 0 suppresses the decimal point. Non-finite values are converted to \texttt{NA}, \texttt{NaN} or (perhaps a sign followed by) \texttt{Inf}.}

\texttt{e, E Double precision value, in “exponential” decimal notation of the form “[\-]m.ddde[+-]xx” or “[\-]m.dde[+-]xx.”}

\texttt{g, G Double precision value, in \%e or \%E format if the exponent is less than \texttt{-4} or greater than or equal to the precision, and \%f format otherwise. (The precision (default 6) specifies the number of significant digits here, whereas in \%f, \%e, \%g, it is the number of digits after the decimal point.)}

\texttt{a, A Double precision value, in binary notation of the form “[\-]0xh.hhhp[+-]d”. This is a binary fraction expressed in hex multiplied by a (decimal) power of 2. The number of hex digits after the decimal point is specified by the precision: the default is enough digits to represent exactly the internal binary representation. Non-finite values are converted to \texttt{NA}, \texttt{NaN} or (perhaps a sign followed by) \texttt{Inf}. Format \texttt{%a} uses lower-case for \texttt{x}, \texttt{p} and the hex values; format \texttt{%A} uses upper-case.

This should be supported on all platforms as it is a feature of C99. The format is not uniquely defined: although it would be possible to make the leading \texttt{h} always zero or one, this is not always done. Most systems will suppress trailing zeros, but a few do not. On a well-written platform, for normal numbers there will be a leading one before the decimal point plus (by default) 13 hexadecimal digits, hence 53 bits. The treatment of denormalized (aka ‘subnormal’) numbers is very platform-dependent.}

\texttt{s Character string. Character \texttt{NA}s are converted to “NA”.}

\texttt{\% Literal \% (none of the extra formatting characters given below are permitted in this case).}

Conversion by \texttt{as.character} is used for non-character arguments with \texttt{s} and by \texttt{as.double} for non-double arguments with \texttt{f, e, E, g, G}. NB: the length is determined before conversion, so do not rely on the internal coercion if this would change the length. The coercion is done only once, so if \texttt{length(fmt) > 1} then all elements must expect the same types of arguments.

In addition, between the initial \% and the terminating conversion character there may be, in any order:

\texttt{m.n Two numbers separated by a period, denoting the field width (m) and the precision (n).}

\texttt{- Left adjustment of converted argument in its field.}

\texttt{+ Always print number with sign: by default only negative numbers are printed with a sign.}

\texttt{a space Prefix a space if the first character is not a sign.}

\texttt{0 For numbers, pad to the field width with leading zeros. For characters, this zero-pads on some platforms and is ignored on others.}
# specifies “alternate output” for numbers, its action depending on the type: For \texttt{x} or \texttt{X}, 0x or 0X will be prefixed to a non-zero result. For \texttt{e}, \texttt{E}, \texttt{g} and \texttt{G}, the output will always have a decimal point; for \texttt{g} and \texttt{G}, trailing zeros will not be removed.

Further, immediately after \% may come 1\$ to 99\$ to refer to a numbered argument: this allows arguments to be referenced out of order and is mainly intended for translators of error messages. If this is done it is best if all formats are numbered: if not the unnumbered ones process the arguments in order. See the examples. This notation allows arguments to be used more than once, in which case they must be used as the same type (integer, double or character).

A field width or precision (but not both) may be indicated by an asterisk \*: in this case an argument specifies the desired number. A negative field width is taken as a ‘-’ flag followed by a positive field width. A negative precision is treated as if the precision were omitted. The argument should be integer, but a double argument will be coerced to integer.

There is a limit of 8192 bytes on elements of \texttt{fmt}, and on strings included from a single \%letter conversion specification.

Field widths and precisions of \%s conversions are interpreted as bytes, not characters, as described in the C standard.

The C doubles used for \texttt{R} numerical vectors have signed zeros, which \texttt{sprintf} may output as \texttt{-0}, \texttt{-0.000} ...

\textbf{Value}

A character vector of length that of the longest input. If any element of \texttt{fmt} or any character argument is declared as UTF-8, the element of the result will be in UTF-8 and have the encoding declared as UTF-8. Otherwise it will be in the current locale’s encoding.

\textbf{Warning}

The format string is passed down the OS’s \texttt{sprintf} function, and incorrect formats can cause the latter to crash the \texttt{R} process. \texttt{R} does perform sanity checks on the format, but not all possible user errors on all platforms have been tested, and some might be terminal.

The behaviour on inputs not documented here is ‘undefined’, which means it is allowed to differ by platform.

Examples

## be careful with the format: most things in R are floats
## only integer-valued reals get coerced to integer.

```r
sprintf("%s is %f feet tall
", "Sven", 7.1)  # OK
try(sprintf("%s is %i feet tall\n", "Sven", 7.1))  # not OK
  sprintf("%s is %i feet tall\n", "Sven", 7)  # OK
```

## use a literal %:

```r
sprintf("%.0f%% said yes (out of a sample of size %.0f)", 66.666, 3)
```

## various formats of pi:

```r
sprintf("%.f", pi)
sprintf("%.3f", pi)
sprintf("%.1f", pi)
sprintf("%05.1f", pi)
sprintf("%.+f", pi)
sprintf("% f", pi)
sprintf("%-10f", pi)  # left justified
sprintf("%e", pi)
sprintf("%E", pi)
sprintf("%g", pi)
sprintf("%g", 1e6 * pi)  # -> exponential
sprintf("%9g", 1e6 * pi)  # -> "fixed"
sprintf("%G", 1e-6 * pi)
```

## no truncation:

```r
sprintf("%1.f", 101)
```

## re-use one argument three times, show difference between %x and %X

```r
xx <- sprintf("%1$d %1$x %1$X", 0:15)
xx <- matrix(xx, dimnames = list(rep("", 16), "%d%x%X"))
noquote(format(xx, justify = "right"))
```

## More sophisticated:

```r
sprintf("min 10-char string '/quotesingle.Var%10s/quotesingle.Var%10s/quotesingle.Var%10s',
  c("a", "ABC", "and an even longer one"))
```

## Platform-dependent bad example from qdapTools 1.0.0:
## may pad with spaces or zeroes.

```r
sprintf("%09s", month.name)
```

```r
n <- 1:18
sprintf(paste0("e with %2d digits = %.", n, "%g"), n, exp(1))
```

## Using arguments out of order

```r
sprintf("second %2$1.0f, first %1$5.2f, third %3$1.0f", pi, 2, 3)
```

## Using asterisk for width or precision

```r
sprintf("precision %.*f, width '%*.3f'", 3, pi, 8, pi)
```

## Asterisk and argument re-use, 'e' example reiterated:
sQuote

```r
sprintf("e with %1$2d digits = %2$.*1$g", n, exp(1))

## re-cycle arguments
sprintf("%s %d", "test", 1:3)

## binary output showing rounding/representation errors
x <- seq(0, 1.0, 0.1); y <- c(0,.1,.2,.3,.4,.5,.6,.7,.8,.9,1)
cbind(x, sprintf("%a", x), sprintf("%a", y))
```

### Description

Single or double quote text by combining with appropriate single or double left and right quotation marks.

### Usage

- `sQuote(x)`
- `dQuote(x)`

### Arguments

- `x` an R object, to be coerced to a character vector.

### Details

The purpose of the functions is to provide a simple means of markup for quoting text to be used in the R output, e.g., in warnings or error messages.

The choice of the appropriate quotation marks depends on both the locale and the available character sets. Older Unix/X11 fonts displayed the grave accent (ASCII code 0x60) and the apostrophe (0x27) in a way that they could also be used as matching open and close single quotation marks. Using modern fonts, or non-Unix systems, these characters no longer produce matching glyphs. Unicode provides left and right single quotation mark characters (U+2018 and U+2019); if Unicode markup cannot be assumed to be available, it seems good practice to use the apostrophe as a non-directional single quotation mark.

Similarly, Unicode has left and right double quotation mark characters (U+201C and U+201D); if only ASCII’s typewriter characteristics can be employed, than the ASCII quotation mark (0x22) should be used as both the left and right double quotation mark.

Some other locales also have the directional quotation marks, notably on Windows. TeX uses grave and apostrophe for the directional single quotation marks, and doubled grave and doubled apostrophe for the directional double quotation marks.

What rendering is used depend on the `options` setting for `useFancyQuotes`. If this is `FALSE` then the undirectional ASCII quotation style is used. If this is `TRUE` (the default), Unicode directional quotes are used are used where available (currently, UTF-8 locales on Unix-alikes and all Windows locales except C): if set to "UTF-8" UTF-8 markup is used (whatever the current locale). If set to "TeX", TeX-style markup is used. Finally, if this is set to a character vector of length four, the first two entries are used for beginning and ending single quotes and the second two for beginning and ending double quotes: this can be used to implement non-English quoting conventions such as the use of guillemets.
Where fancy quotes are used, you should be aware that they may not be rendered correctly as not all fonts include the requisite glyphs: for example some have directional single quotes but not directional double quotes.

**Value**

A character vector of the same length as `x` (after any coercion) in the current locale’s encoding.

**References**

**See Also**

*Quotes* for quoting R code.

*shQuote* for quoting OS commands.

**Examples**

```r
op <- options("useFancyQuotes")
paste("argument", sQuote("x"), "must be non-zero")
options(useFancyQuotes = FALSE)
cat("\'ndistinguish plain", sQuote("single"), "and",
    dQuote("double"), "quotes\n")
options(useFancyQuotes = TRUE)
cat("\'ndistinguish fancy", sQuote("single"), "and",
    dQuote("double"), "quotes\n")
options(useFancyQuotes = "TeX")
cat("\'ndistinguish TeX", sQuote("single"), "and",
    dQuote("double"), "quotes\n")
if(!l10n_info()$Latin-1) {
    options(useFancyQuotes = c("\xab", "\xbb", "\xbf", ")")
cat("\n", sQuote("guillemet"), "and",
    dQuote("Spanish question"), "styles\n")
} else if(!l10n_info()$UTF-8) {
    options(useFancyQuotes = c("\xc2\xab", "\xc2\xbb", "\xc2\xbf", ")")
cat("\n", sQuote("guillemet"), "and",
    dQuote("Spanish question"), "styles\n")
}
options(op)
```

**Description**

These functions are for working with source files and more generally with “source references” ("srcref"), i.e., references to source code. The resulting data is used for printing and source level debugging, and is typically available in interactive R sessions, namely when `options(keep.source = TRUE)`.
Usage

srcfile(filename, encoding = getOption("encoding"), Enc = "unknown")
srcfilecopy(filename, lines, timestamp = Sys.time(), isFile = FALSE)
srcfilealias(filename, srcfile)
getSrcLines(srcfile, first, last)
srcref(srcfile, lloc)

## S3 method for class 'srcfile'
print(x, ...)
## S3 method for class 'srcfile'
summary(object, ...)
## S3 method for class 'srcfile'
open(con, line, ...)
## S3 method for class 'srcfile'
close(con, ...)
## S3 method for class 'srcref'
print(x, useSource = TRUE, ...)
## S3 method for class 'srcref'
summary(object, useSource = FALSE, ...)
## S3 method for class 'srcref'
as.character(x, useSource = TRUE, to = x, ...)
.isOpen(srcfile)

Arguments

filename The name of a file.
encoding The character encoding to assume for the file.
Enc The encoding with which to make strings: see the encoding argument of parse
lines A character vector of source lines. Other R objects will be coerced to character.
timestamp The timestamp to use on a copy of a file.
isFile Is this srcfilecopy known to come from a file system file?
srcfile A srcfile object.
first, last, line Line numbers.
lloc A vector of four, six or eight values giving a source location; see ‘Details’.
x, object, con An object of the appropriate class.
useSource Whether to read the srcfile to obtain the text of a srcref.
to An optional second srcref object to mark the end of the character range.
... Additional arguments to the methods; these will be ignored.

Details

These functions and classes handle source code references.

The srcfile function produces an object of class srcfile, which contains the name and directory of a source code file, along with its timestamp, for use in source level debugging (not yet implemented) and source echoing. The encoding of the file is saved; see file for a discussion of encodings, and iconvlist for a list of allowable encodings on your platform.

The srcfilecopy function produces an object of the descendant class srcfilecopy, which saves the source lines in a character vector. It copies the value of the isFile argument, to help debuggers identify whether this text comes from a real file in the file system.
The `srcfilealias` function produces an object of the descendant class `srcfilealias`, which gives an alternate name to another `srcfile`. This is produced by the parser when a `#line` directive is used.

The `getSrcLines` function reads the specified lines from `srcfile`.

The `srcref` function produces an object of class `srcref`, which describes a range of characters in a `srcfile`. The `lloc` value gives the following values:

```r
c(first_line, first_byte, last_line, last_byte, first_column, 
  last_column, first_parsed, last_parsed)
```

Bytes (elements 2, 4) and columns (elements 5, 6) may be different due to multibyte characters. If only four values are given, the columns and bytes are assumed to match. Lines (elements 1, 3) and parsed lines (elements 7, 8) may differ if a `#line` directive is used in code: the former will respect the directive, the latter will just count lines. If only 4 or 6 elements are given, the parsed lines will be assumed to match the lines.

Methods are defined for `print`, `summary`, `open`, and `close` for classes `srcfile` and `srcfilecopy`. The open method opens its internal `file` connection at a particular line; if it was already open, it will be repositioned to that line.

Methods are defined for `print`, `summary` and `as.character` for class `srcref`. The `as.character` method will read the associated source file to obtain the text corresponding to the reference. If the `to` argument is given, it should be a second `srcref` that follows the first, in the same file; they will be treated as one reference to the whole range. The exact behaviour depends on the class of the source file. If the source file inherits from class `srcfilecopy`, the lines are taken from the saved copy using the “parsed” line counts. If not, an attempt is made to read the file, and the original line numbers of the `srcref` record (i.e., elements 1 and 3) are used. If an error occurs (e.g., the file no longer exists), text like `<srcref: “file” chars 1:1 to 2:10>` will be returned instead, indicating the line:column ranges of the first and last character. The `summary` method defaults to this type of display.

Lists of `srcref` objects may be attached to expressions as the "`srcref`" attribute. (The list of `srcref` objects should be the same length as the expression.) By default, expressions are printed by `print.default` using the associated `srcref`. To see deparsed code instead, call `print` with argument `useSource = FALSE`. If a `srcref` object is printed with `useSource = FALSE`, the `<srcref: ...>` record will be printed.

`.isOpen` is intended for internal use: it checks whether the connection associated with a `srcfile` object is open.

### Value

- `srcfile` returns a `srcfile` object.
- `srcfilecopy` returns a `srcfilecopy` object.
- `getSrcLines` returns a `srcfilecopy` object.
- `srcref` returns a `srcref` object.

### Author(s)

Duncan Murdoch

### See Also

- `getSrcFilename` for extracting information from a source reference, or `removeSource` to remove it from a (non-primitive) function (aka 'closure').
Examples

```r
# has timestamp
src <- srcfile(system.file("DESCRIPTION", package = "base"))
summary(src)
getSrcLines(src, 1, 4)
ref <- srcref(src, c(1, 1, 2, 1000))
ref
print(ref, useSource = FALSE)
```

standardGeneric

Formal Method System – Dispatching S4 Methods

Description

The function `standardGeneric` initiates dispatch of S4 methods: see the references and the documentation of the `methods` package. Usually, calls to this function are generated automatically and not explicitly by the programmer.

Usage

`standardGeneric(f, fdef)`

Arguments

- `f` The name of the generic.
- `fdef` The generic function definition. Never passed when defining a new generic.

Details

`standardGeneric` dispatches the method defined for a generic function named `f`, using the actual arguments in the frame from which it is called.

The argument `fdef` is inserted (automatically) when dispatching methods for a primitive function. If present, it must always be the function definition for the corresponding generic. Don’t insert this argument by hand, as there is no validity checking and miss-specifying the function definition will cause certain failure.

For more, use the `methods` package, and see the documentation in `GenericFunctions`.

Does String Start or End With Another String?

**Description**

Determines if entries of `x` start or end with string (entries of) `prefix` or `suffix` respectively, where strings are recycled to common lengths.

```r
startsWith() is equivalent to but much faster than
```

```r
substring(x, 1, nchar(prefix)) == prefix
```

or also

```r
grepl("^<prefix>", x)
```

where `prefix` is not to contain special regular expression characters.

**Usage**

```r
startsWith(x, prefix)
endsWith(x, suffix)
```

**Arguments**

- `x` vector of `character` string whose “starts” are considered.
- `prefix, suffix` `character` vector (often of length one).

**Details**

The code has an optimized branch for the most common usage in which `prefix` or `suffix` is of length one, and is further optimized in a UTF-8 or 8-byte locale if that is an ASCII string.

**Value**

A `logical` vector, of “common length” of `x` and `prefix` (or `suffix`), i.e., of the longer of the two lengths unless one of them is zero when the result is also of zero length. A shorter input is recycled to the output length.

**See Also**

`grepl`, `substring`; the partial string matching functions `charmatch` and `pmatch` solve a different task.

**Examples**

```r
startsWith(search(), "package:" ) # typically at least two FALSE, nowadays often three
x1 <- c("Foobar", "bla bla", "something", "another", "blu", "brown",
"blau blüht der Enzian") # non-ASCII
x2 <- cbind(
startsWith(x1, "b"),
startsWith(x1, "bl")
)
```
startsWith(x1, "bla"),
endsWith(x1, "n"),
endsWith(x1, "an")
rownames(x2) <- x1; colnames(x2) <- c("b", "b1", "bla", "n", "an")
x2
```

**Description**

In R, the startup mechanism is as follows.

 Unless '--no-environ' was given on the command line, R searches for site and user files to process for setting environment variables. The name of the site file is the one pointed to by the environment variable R_ENVIRON; if this is unset, 'R_HOME/etc/Renviron.site' is used (if it exists, which it does not in a 'factory-fresh' installation). The name of the user file can be specified by the R_ENVIRON_USER environment variable; if this is unset, the files searched for are '.Renviron' in the current or in the user's home directory (in that order). See 'Details' for how the files are read.

Then R searches for the site-wide startup profile file of R code unless the command line option '--no-site-file' was given. The path of this file is taken from the value of the R_PROFILE environment variable (after tilde expansion). If this variable is unset, the default is 'R_HOME/etc/Rprofile.site', which is used if it exists (which it does not in a 'factory-fresh' installation). This code is sourced into the base package. Users need to be careful not to unintentionally overwrite objects in base, and it is normally advisable to use local if code needs to be executed: see the examples.

Then, unless '--no-init-file' was given, R searches for a user profile, a file of R code. The path of this file can be specified by the R_PROFILE_USER environment variable (and tilde expansion will be performed). If this is unset, a file called '.Rprofile' is searched for in the current directory or in the user's home directory (in that order). The user profile file is sourced into the workspace.

Note that when the site and user profile files are sourced only the base package is loaded, so objects in other packages need to be referred to by e.g. utils::dump.frames or after explicitly loading the package concerned.

R then loads a saved image of the user workspace from '.RData' in the current directory if there is one (unless '--no-restore-data' or '--no-restore' was specified on the command line).

Next, if a function .First is found on the search path, it is executed as .First(). Finally, function .First.sys() in the base package is run. This calls require to attach the default packages specified by options("defaultPackages"). If the methods package is included, this will have been attached earlier (by function .OptRequireMethods()) so that namespace initializations such as those from the user workspace will proceed correctly.

A function .First (and .Last) can be defined in appropriate '.Rprofile' or 'Rprofile.site' files or have been saved in '.RData'. If you want a different set of packages than the default ones when you start, insert a call to options in the '.Rprofile' or 'Rprofile.site' file. For example, options(defaultPackages = character()) will attach no extra packages on startup (only the base package) (or set R_DEFAULT_PACKAGES=NULL as an environment variable before running R). Using options(defaultPackages = "") or R_DEFAULT_PACKAGES="" enforces the R system default.

On front-ends which support it, the commands history is read from the file specified by the environment variable R_HISTFILE (default '.Rhistory' in the current directory) unless '--no-restore-history' or '--no-restore' was specified.
The command-line option ‘--vanilla’ implies ‘--no-site-file’, ‘--no-init-file’, ‘--no-environ’ and (except for \texttt{R CMD}) ‘--no-restore’.

**Details**

Note that there are two sorts of files used in startup: environment files which contain lists of environment variables to be set, and profile files which contain \texttt{R} code.

Lines in a site or user environment file should be either comment lines starting with \#, or lines of the form name=value. The latter sets the environmental variable name to value, overriding an existing value. If value contains an expression of the form $\{foo-bar\}$, the value is that of the environmental variable foo if that exists and is set to a non-empty value, otherwise bar. (If it is of the form $\{foo\}$, the default is ’\$\texttt{\textasciitilde HOME}\$’. This construction can be nested, so bar can be of the same form (as in $\{foo-$\{bar-blah\}$\}$). Note that the braces are essential: for example $\$\texttt{\textasciitilde HOME}\$\$ \texttt{\textasciitilde HOME}$ will not be interpreted.

Leading and trailing white space in value are stripped. value is then processed in a similar way to a Unix shell: in particular the outermost level of (single or double) quotes is stripped, and backslashes are removed except inside quotes.

On systems with sub-architectures (mainly Windows), the files ‘\texttt{Renviron.site}’ and ‘\texttt{Rprofile.site}’ are looked for first in architecture-specific directories, e.g. ‘\texttt{R_HOME/etc/i386/Renviron.site}’. And e.g. ‘\texttt{.Renviron.i386}’ will be used in preference to ‘\texttt{.Renviron}’.

**Note**

It is not intended that there be interaction with the user during startup code. Attempting to do so can crash the \texttt{R} process.

On Unix versions of \texttt{R} here is also a file ‘\texttt{R_HOME/etc/Renviron}’ which is read very early in the start-up processing. It contains environment variables set by \texttt{R} in the configure process. Values in that file can be overridden in site or user environment files: do not change ‘\texttt{R_HOME/etc/Renviron}’ itself. Note that this is distinct from ‘\texttt{R_HOME/etc/Renviron.site}’.

Command-line options may well not apply to alternative front-ends: they do not apply to \texttt{R.app} on macOS. \texttt{R CMD check} and \texttt{R CMD build} do not always read the standard startup files, but they do always read specific ‘\texttt{Renviron}’ files. The location of these can be controlled by the environment variables \texttt{R_CHECK_ENVIRON} and \texttt{R_BUILD_ENVIRON}. If these are set their value is used as the path for the ‘\texttt{Renviron}’ file; otherwise, files ‘\texttt{~/.R/check.Renviron}’ or ‘\texttt{~/.R/build.Renviron}’ or sub-architecture-specific versions are employed.

If you want ‘\texttt{~/.Renviron}’ or ‘\texttt{~/.Rprofile}’ to be ignored by child \texttt{R} processes (such as those run by \texttt{R CMD check} and \texttt{R CMD build}), set the appropriate environment variable \texttt{R_ENVIRON_USER} or \texttt{R_PROFILE_USER} to (if possible, which it is not on Windows) ’’ or to the name of a non-existent file.

**See Also**

For the definition of the ‘home’ directory on Windows see the ‘\texttt{rw-FAQ}’ Q2.14. It can be found from a running \texttt{R} by \texttt{Sys.getenv("R\_USER")}. \texttt{.Last} for final actions at the close of an \texttt{R} session. \texttt{commandArgs} for accessing the command line arguments.

There are examples of using startup files to set defaults for graphics devices in the help for \texttt{X11} and \texttt{quartz}. 
An Introduction to R for more command-line options: those affecting memory management are covered in the help file for Memory.

readRenviron to read ‘.Renviron’ files.

For profiling code, see Rprof.

Examples

## Not run:
## Example ~/.Renviron on Unix
R_LIBS=~/R/library
PAGER=/usr/local/bin/less

## Example .Renviron on Windows
R_LIBS=C:/R/library
MY_TCLTK=c:/Program Files/Tcl/bin"

## Example of setting R_DEFAULT_PACKAGES (from R CMD check)
R_DEFAULT_PACKAGES='utils,grDevices,graphics,stats'
# this loads the packages in the order given, so they appear on
# the search path in reverse order.

## Example of .Rprofile
options(width=65, digits=5)
ocations(show.signif.stars=FALSE)
setHook(packageEvent("grDevices", "onLoad"),
    function(...) grDevices::ps.options(horizontal=FALSE))
set.seed(1234)
.First <- function() cat("\n Welcome to R!\n\n")
.Last <- function() cat("\n Goodbye!\n\n")

## Example of Rprofile.site
local(
    # add MASS to the default packages, set a CRAN mirror
    old <- getOption("defaultPackages"); r <- getOption("repos")
r["CRAN"] <- "http://my.local.cran"
options(defaultPackages = c(old, "MASS"), repos = r)
    # (for Unix terminal users) set the width from COLUMNS if set
cols <- Sys.getenv("COLUMNS")
    if(nzchar(cols)) options(width = as.integer(cols))
    # interactive sessions get a fortune cookie (needs fortunes package)
    if (interactive())
        fortunes::fortune()
)

## if .Renviron contains
FOOBAR="coo\bar\doh\ex"abc"def"

## then we get
# > cat(Sys.getenv("FOOBAR"), "\n")
# coo\bardoh\exabc"def"

## End(Not run)
Description

stop stops execution of the current expression and executes an error action.
geterrmessage gives the last error message.

Usage

stop(..., call. = TRUE, domain = NULL)
geterrmessage()

Arguments

... zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
call. logical, indicating if the call should become part of the error message.
domain see gettext. If NA, messages will not be translated.

Details

The error action is controlled by error handlers established within the executing code and by the current default error handler set by options(error=). The error is first signaled as if using signalCondition(). If there are no handlers or if all handlers return, then the error message is printed (if options("show.error.messages") is true) and the default error handler is used. The default behaviour (the NULL error-handler) in interactive use is to return to the top level prompt or the top level browser, and in non-interactive use to (effectively) call q("no", status = 1, runLast = FALSE). The default handler stores the error message in a buffer; it can be retrieved by geterrmessage(). It also stores a trace of the call stack that can be retrieved by traceback().

Errors will be truncated to getOption("warning.length") characters, default 1000.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a warning.

Value

geterrmessage gives the last error message, as a character string ending in "\n".

Note

Use domain = NA whenever ... contain a result from gettextf() as that is translated already.

References

stopifnot

See Also

warning, try to catch errors and retry, and options for setting error handlers. stopifnot for validity testing. tryCatch and withCallingHandlers can be used to establish custom handlers while executing an expression. gettext for the mechanisms for the automated translation of messages.

Examples

iter <- 12
try(if(iter > 10) stop("too many iterations"))

tst1 <- function(...) stop("dummy error")
try(tst1(1:10, long, calling, expression))

tst2 <- function(...) stop("dummy error", call. = FALSE)
try(tst2(1:10, longcalling, expression, but.not.seen.in.Error))

stopifnot

Ensure the Truth of R Expressions

Description

If any of the expressions in ... are not all TRUE, stop is called, producing an error message indicating the first of the elements of ... which were not true.

Usage

stopifnot(...)

Arguments

... any number of (logical) R expressions, which should evaluate to TRUE.

Details

This function is intended for use in regression tests or also argument checking of functions, in particular to make them easier to read.
stopifnot(A, B) is conceptually equivalent to

{ if(any(is.na(A)) || !all(A)) stop(...);
  if(any(is.na(B)) || !all(B)) stop(...) }

Since R version 3.5.0, expressions are evaluated sequentially, and hence evaluation stops as soon as there is a "non-TRUE", as indicated by the above conceptual equivalence statement. Further, when such an expression signals an error or warning, its conditionCall() no longer contains the full stopifnot call, but just the erroneous expression.
Since R version 3.4.0, when an expression (from ...) is not true and is a call to all.equal, the error message will report the (first part of the) differences reported by all.equal(*).

Value

(NULL if all statements in ... are TRUE.)
See Also

`stop`, `warning`; `assertCondition` in package `tools` complements `stopifnot()` for testing warnings and errors.

Examples

```r
stopifnot(1 == 1, all.equal(pi, 3.14159265), 1 < 2) # all TRUE

m <- matrix(c(1,3,3,1), 2, 2)
stopifnot(m == t(m), diag(m) == rep(1, 2)) # all(.) |=> TRUE

op <- options(error = expression(NULL))
# "disabling stop(.)" << Use with CARE! >>

stopifnot(all.equal(pi, 3.141593), 2 < 2, all(1:10 < 12), "a" < "b")
stopifnot(all.equal(pi, 3.1415927), 2 < 2, all(1:10 < 12), "a" < "b")

# long all.equal() error messages are abbreviated:
stopifnot(all.equal(rep(list(pi),4), list(3.1, 3.14, 3.141, 3.1415)))

options(op) # revert to previous error handler
```

---

### strptime

**Date-time Conversion Functions to and from Character**

**Description**

Functions to convert between character representations and objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

**Usage**

```r
## S3 method for class 'POSIXct'
format(x, format = "", tz = "", usetz = FALSE, ...)
## S3 method for class 'POSIXlt'
format(x, format = "", usetz = FALSE, ...)

## S3 method for class 'POSIXt'
as.character(x, ...)

strftime(x, format = "", tz = "", usetz = FALSE, ...)
strptime(x, format, tz = "")
```

**Arguments**

- `x` An object to be converted: a character vector for `strptime`, an object which can be converted to "POSIXlt" for `strftime`.
- `tz` A character string specifying the time zone to be used for the conversion. System-specific (see `as.POSIXlt`), but "" is the current time zone, and "GMT" is UTC. Invalid values are most commonly treated as UTC, on some platforms with a warning.
format  A character string. The default for the format methods is 
"%Y-%m-%d %H:%M:%S" if any element has a time component which is 
not midnight, and "%Y-%m-%d" otherwise. If options("digits.secs") is set, 
up to the specified number of digits will be printed for seconds.

... Further arguments to be passed from or to other methods.

usetz  logical. Should the time zone abbreviation be appended to the output? This is 
used in printing times, and more reliable than using 
"%Z".

Details
The format and as.character methods and strftime convert objects from the classes "POSIXlt" 
and "POSIXct" to character vectors.

strftime converts character vectors to class "POSIXlt": its input x is first converted by 
as.character. Each input string is processed as far as necessary for the format specified: any 
trailing characters are ignored.

strftime is a wrapper for format.POSIXlt, and it and format.POSIXct first convert to class 
"POSIXlt" by calling as.POSIXlt (so they also work for class "Date"). Note that only that con-
version depends on the time zone.

The usual vector re-cycling rules are applied to x and format so the answer will be of length of the 
longer of these vectors.

Locale-specific conversions to and from character strings are used where appropriate and available.
This affects the names of the days and months, the AM/PM indicator (if used) and the separators in 
output formats such as %x and %X, via the setting of the LC_TIME locale category. The 'current locale' 
of the descriptions might mean the locale in use at the start of the R session or when these functions 
are first used. (For input, the locale-specific conversions can be changed by calling Sys.setlocale 
with category LC_TIME since R 3.1.0 or LC_ALL since R 3.4.1. For output, what happens depends 
on the OS.)

The details of the formats are platform-specific, but the following are likely to be widely available:
most are defined by the POSIX standard. A conversion specification is introduced by %, usually 
followed by a single letter or O or E and then a single letter. Any character in the format string 
not part of a conversion specification is interpreted literally (and %% gives %). Widely implemented conversion specifications include

%a  Abbreviated weekday name in the current locale on this platform. (Also matches full name on 
input: in some locales there are no abbreviations of names.)

%A  Full weekday name in the current locale. (Also matches abbreviated name on input.)

%b  Abbreviated month name in the current locale on this platform. (Also matches full name on 
input: in some locales there are no abbreviations of names.)

%B  Full month name in the current locale. (Also matches abbreviated name on input.)

%c  Date and time. Locale-specific on output, "%a %b %e %H:%M:%S %Y" on input.

%c  Century (00–99): the integer part of the year divided by 100.

%d  Day of the month as decimal number (01–31).

%D  Date format such as %m/%d/%y: the C99 standard says it should be that exact format (but not all 
OSes comply).

%e  Day of the month as decimal number (1–31), with a leading space for a single-digit number.

%F  Equivalent to %Y-%m-%d (the ISO 8601 date format).

%g  The last two digits of the week-based year (see %v). (Accepted but ignored on input.)

%G  The week-based year (see %V) as a decimal number. (Accepted but ignored on input.)
\%h Equivalent to \%b.
\%H Hours as decimal number (00–23). As a special exception strings such as ‘24:00:00’ are accepted for input, since ISO 8601 allows these.
\%H Hours as decimal number (01–12).
\%j Day of year as decimal number (001–366).
\%m Month as decimal number (01–12).
\%m Minute as decimal number (00–59).
\%n Newline on output, arbitrary whitespace on input.
\%p AM/PM indicator in the locale. Used in conjunction with \%I and not with \%h. An empty string in some locales (for example on some OSes, non-English European locales including Russia).
Character is undefined if used for input in such a locale.
Some platforms accept \%p for output, which uses a lower-case version (\%p may also use lower case): others will output P.
\%r For output, the 12-hour clock time (using the locale’s AM or PM): only defined in some locales, and on some OSes misleading in locales which do not define an AM/PM indicator. For input, equivalent to \%I:\%M:\%S \%p.
\%R Equivalent to \%H:\%M.
\%S Second as integer (00–61), allowing for up to two leap-seconds (but POSIX-compliant implementations will ignore leap seconds).
\%t Tab on output, arbitrary whitespace on input.
\%T Equivalent to \%H:\%M:\%S.
\%u Weekday as a decimal number (1–7, Monday is 1).
\%W Week of the year as decimal number (00–53) using Monday as the first day of the year (and typically with the first Sunday of the year as day 1 of week 1). The UK convention.
\%v Week of the year as decimal number (01–53) as defined in ISO 8601. If the week (starting on Monday) containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1. (Accepted but ignored on input.)
\%w Weekday as decimal number (0–6, Sunday is 0).
\%w Week of the year as decimal number (00–53) using Monday as the first day of week (and typically with the first Monday of the year as day 1 of week 1). The UK convention.
\%x Date. Locale-specific on output, "%y/%m/%d" on input.
\%X Time. Locale-specific on output, "%H:%M:%S" on input.
\%y Year without century (00–99). On input, values 00 to 68 are prefixed by 20 and 69 to 99 by 19 – that is the behaviour specified by the 2004 and 2008 POSIX standards, but they do also say ‘it is expected that in a future version the default century inferred from a 2-digit year will change’.
\%Y Year with century. Note that whereas there was no zero in the original Gregorian calendar, ISO 8601:2004 defines it to be valid (interpreted as 1BC): see https://en.wikipedia.org/wiki/0_(year). Note that the standards also say that years before 1582 in its calendar should only be used with agreement of the parties involved.
For input, only years 0:9999 are accepted.
\%z Signed offset in hours and minutes from UTC, so ~0800 is 8 hours behind UTC. Values up to +1400 are accepted. (Standard only for output.)
\%Z (Output only.) Time zone abbreviation as a character string (empty if not available). This may not be reliable when a time zone has changed abbreviations over the years.
Where leading zeros are shown they will be used on output but are optional on input. Names are matched case-insensitively on input: whether they are capitalized on output depends on the platform and the locale. Note that abbreviated names are platform-specific (although the standards specify that in the ‘C’ locale they must be the first three letters of the capitalized English name: this convention is widely used in English-language locales but for example the French month abbreviations are not the same on any two of Linux, macOS, Solaris and Windows). Knowing what the abbreviations are is essential if you wish to use %a, %b or %h as part of an input format: see the examples for how to check.

When %Z or %z is used for output with an object with an assigned time zone an attempt is made to use the values for that time zone — but it is not guaranteed to succeed.

Not in the standards and less widely implemented are

%k The 24-hour clock time with single digits preceded by a blank.
%l The 12-hour clock time with single digits preceded by a blank.
%S (Output only.) The number of seconds since the epoch.
%+ (Output only.) Similar to %c, often "%a %b %e %H:%M:%S %Z %Y". May depend on the locale.

For output there are also %x, %X, %y, %Y, %j, %w, %U, %W, %G, %u, %z, %Z, %s, %c, %S, %K, %L, %S

The behaviour of other conversion specifications (and even if other character sequences commencing with % are conversion specifications) is system-specific. Some systems document that the use of multi-byte characters in format is unsupported: UTF-8 locales are unlikely to cause a problem.

The format methods and strptime return character vectors representing the time. NA times are returned as NA_character_. The elements are restricted to 256 bytes, plus a time zone abbreviation if usetz is true. (On known platforms longer strings are truncated at 255 or 256 bytes, but this is not guaranteed by the C99 standard.)

strptime turns character representations into an object of class "POSIXlt". The time zone is used to set the isdst component and to set the "tzname" attribute if tz != "". If the specified time is invalid (for example "2010-02-30 08:00") all the components of the result are NA. (NB: this does means exactly what it says – if it is an invalid time, not just a time that does not exist in some time zone.)

Printing years

Everyone agrees that years from 1000 to 9999 should be printed with 4 digits, but the standards do not define what is to be done outside that range. For years 0 to 999 most OSes pad with zeros or spaces to 4 characters, and Linux outputs just the number.

OS facilities will probably not print years before 1 CE (aka 1 AD) ‘correctly’ (they tend to assume the existence of a year 0: see https://en.wikipedia.org/wiki/0_(year), and some OSes get them completely wrong). Common formats are -45 and -045.

Years after 9999 and before -999 are normally printed with five or more characters.
Some platforms support modifiers from POSIX 2008 (and others). On Linux the format "%04Y" assures a minimum of four characters and zero-padding. The internal code (as used on Windows and by default on macOS) uses zero-padding by default, and formats %_4Y and %_Y can be used for space padding and no padding.

Time zone offsets

Offsets from GMT (also known as UTC) are part of the conversion between timezones and to/from class "POSIXct", but cause difficulties as they often computed incorrectly.

They conventionally have the opposite sign from time-zone specifications (see Sys.timezone): positive values are East of the meridian. Although there have been time zones with offsets like 00:09:21 (Paris in 1900), and 00:44:30 (Liberia until 1972), offsets are usually treated as whole numbers of minutes, and are most often seen in RFC 822 email headers in forms like -0800 (e.g., used on the Pacific coast of the US in winter).

Format %z can be used for input or output: it is a character string, conventionally plus or minus followed by two digits for hours and two for minutes: the standards say that an empty string should be output if the offset is unknown, but some systems use the offsets for the time zone in use for the current year.

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as "2001-02-28" and a time as "14:01:02" using leading zeroes as here. (The ISO form uses no space to separate dates and times: R does by default.)

For strftime the input string need not specify the date completely: it is assumed that unspecified seconds, minutes or hours are zero, and an unspecified year, month or day is the current one. (However, if a month is specified, the day of that month has to be specified by %d or %e since the current day of the month need not be valid for the specified month.) Some components may be returned as NA (but an unknown tzone component is represented by an empty string).

If the time zone specified is invalid on your system, what happens is system-specific but it will probably be ignored.

Remember that in most time zones some times do not occur and some occur twice because of transitions to/from ‘daylight saving’ (also known as ‘summer’) time. strftime does not validate such times (it does not assume a specific time zone), but conversion by as.POSIXct will do so. Conversion by strftime and formatting/printing uses OS facilities and may return nonsensical results for non-existent times at DST transitions.

In a C locale %c is required to be "%a %b %e %H:%M:%S %Y". As Windows does not comply (and uses a date format not understood outside N. America), that format is used by R on Windows in all locales.

References

The POSIX 1003.1 standard, which is in some respects stricter than ISO 8601.
See Also

DateTimeClasses for details of the date-time classes; locales to query or set a locale.

Your system’s help page on strftime to see how to specify their formats. (On some systems, including Windows, strftime is replaced by more comprehensive internal code.)

Examples

## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y %Z")

## time to sub-second accuracy (if supported by the OS)
format(Sys.time(), "%H:%M:%OS3")

## read in date info in format 'ddmmmyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- strptime(x, "%d%b%Y")
## Sys.setlocale("LC_TIME", lct)
z

## read in date/time info in format 'm/d/y h:m:s'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
x <- paste(dates, times)
strptime(x, "%m/%d/%y %H:%M:%S")

## time with fractional seconds
z <- strptime("20/2/06 11:16:16.683", "%d/%m/%y %H:%M:%OS")
z # prints without fractional seconds
op <- options(digits.secs = 3)
z
options(op)

## time zones name are not portable, but 'EST5EDT' comes pretty close.
(x <- strptime(c("2006-01-08 10:07:52", "2006-08-07 19:33:02"),
  "%Y-%m-%d %H:%M:%S", tz = "EST5EDT"))
attr(x, "tzone")

## An RFC 822 header (Eastern Canada, during DST)
strptime("Tue, 23 Mar 2010 14:36:38 -0400", "%a, %d %b %Y %H:%M:%S %z")

## Make sure you know what the abbreviated names are for you if you wish
## to use them for input (they are matched case-insensitively):
format(seq.Date(as.Date("1978-01-01"), by = 'day', len = 7), "%a")
format(seq.Date(as.Date("2000-01-01"), by = 'month', len = 12), "%b")

---

### strep

Repeat the Elements of a Character Vector

**Description**

Repeat the character strings in a character vector a given number of times (i.e., concatenate the respective numbers of copies of the strings).
Usage

`strrep(x, times)`

Arguments

- `x`: a character vector, or an object which can be coerced to a character vector using `as.character`.
- `times`: an integer vector giving the (non-negative) numbers of times to repeat the respective elements of `x`.

Details

The elements of `x` and `times` will be recycled as necessary (if one has no elements, and empty character vector is returned). Missing elements in `x` or `times` result in missing elements of the return value.

Value

A character vector with the elements of the given character vector repeated the given numbers of times.

Examples

```r
strrep("ABC", 2)
strrep(c("A", "B", "C"), 1 : 3)
## Create vectors with the given numbers of spaces:
strrep(" ", 1 : 5)
```

strsplit

`strsplit` *Split the Elements of a Character Vector*

Description

Split the elements of a character vector `x` into substrings according to the matches to substring `split` within them.

Usage

`strsplit(x, split, fixed = FALSE, perl = FALSE, useBytes = FALSE)`

Arguments

- `x`: character vector, each element of which is to be split. Other inputs, including a factor, will give an error.
- `split`: character vector (or object which can be coerced to such) containing regular expression(s) (unless `fixed = TRUE`) to use for splitting. If empty matches occur, in particular if `split` has length 0, `x` is split into single characters. If `split` has length greater than 1, it is re-cycled along `x`.
- `fixed`: logical. If `TRUE` match `split` exactly, otherwise use regular expressions. Has priority over `perl`.
- `perl`: logical. Should Perl-compatible regexps be used?
useBytes logical. If TRUE the matching is done byte-by-byte rather than character-by-character, and inputs with marked encodings are not converted. This is forced (with a warning) if any input is found which is marked as "bytes" (see Encoding).

Details

Argument split will be coerced to character, so you will see uses with split = NULL to mean split = character(0), including in the examples below.

Note that splitting into single characters can be done via split = character(0) or split = ""; the two are equivalent. The definition of ‘character’ here depends on the locale: in a single-byte locale it is a byte, and in a multi-byte locale it is the unit represented by a ‘wide character’ (almost always a Unicode code point).

A missing value of split does not split the corresponding element(s) of x at all.

The algorithm applied to each input string is

   repeat {
      if the string is empty
         break.
      if there is a match
         add the string to the left of the match to the output.
         remove the match and all to the left of it.
      else
         add the string to the output.
         break.
   }

Note that this means that if there is a match at the beginning of a (non-empty) string, the first element of the output is "", but if there is a match at the end of the string, the output is the same as with the match removed.

Invalid inputs in the current locale are warned about up to 5 times.

Value

A list of the same length as x, the i-th element of which contains the vector of splits of x[i].

If any element of x or split is declared to be in UTF-8 (see Encoding), all non-ASCII character strings in the result will be in UTF-8 and have their encoding declared as UTF-8. For perl = TRUE, useBytes = FALSE all non-ASCII strings in a multibyte locale are translated to UTF-8.

See Also

paste for the reverse, grep and sub for string search and manipulation; also nchar, substr.

‘regular expression’ for the details of the pattern specification.

Option PCRE_use_JIT controls the details when perl = TRUE.

Examples

   noquote(strsplit("A text I want to display with spaces", NULL)[[1]])

   x <- c(as = "asfef", qu = "qwerty", "yuiop[", "b", "stuff.blah.yech")
   # split x on the letter e
strsplit(x, "e")

unlist(strsplit("a.b.c", "."))

## [1] "" "" "" "" ""

## Note that 'split' is a regexp!
## If you really want to split on '.', use
unlist(strsplit("a.b.c", "[.]"))

## [1] "a" "b" "c"

## or
unlist(strsplit("a.b.c", ".", fixed = TRUE))

## a useful function: rev() for strings
strReverse <- function(x)
  sapply(lapply(strsplit(x, NULL), rev), paste, collapse = "")
strReverse(c("abc", "Statistics"))

## get the first names of the members of R-core
a <- readLines(file.path(R.home("doc"),"AUTHORS"))[-(1:8)]
a <- a[(0:2)-length(a)]
(a <- sub(" .*" , "", a))
# and reverse them
strReverse(a)

## Note that final empty strings are not produced:
strsplit(paste(c("", "a", ""), collapse="#"), split="#")[[1]]

## [1] "" "" "" "" ""

## and also an empty string is only produced before a definite match:
strsplit("", "")[[1]] # character(0)
strsplit("", "")[[1]] # [1] ""

---

### strtoi

#### Convert Strings to Integers

**Description**

Convert strings to integers according to the given base using the C function `strtol`, or choose a suitable base following the C rules.

**Usage**

```r
strtoi(x, base = 0L)
```

**Arguments**

- `x` a character vector, or something coercible to this by `as.character`.
- `base` an integer which is between 2 and 36 inclusive, or zero (default).

**Details**

Conversion is based on the C library function `strtol`.

For the default `base = 0L`, the base chosen from the string representation of that element of `x`, so different elements can have different bases (see the first example). The standard C rules for choosing
the base are that octal constants (prefix \texttt{0} not followed by \texttt{x} or \texttt{X}) and hexadecimal constants (prefix \texttt{0x} or \texttt{0X}) are interpreted as base 8 and 16; all other strings are interpreted as base 10.

For a base greater than 10, letters a to z (or A to Z) are used to represent 10 to 35.

**Value**

An integer vector of the same length as \texttt{x}. Values which cannot be interpreted as integers or would overflow are returned as \texttt{NA\_integer\_}.

**See Also**

For decimal strings \texttt{as.integer} is equally useful.

**Examples**

```r
strtoi(c("0xff", "077", "123"))
strtoi(c("ffff", "FFFF"), 16L)
strtoi(c("177", "377"), 8L)
```

---

### strtrim

**Trim Character Strings to Specified Display Widths**

**Description**

Trim character strings to specified display widths.

**Usage**

`strtrim(x, width)`

**Arguments**

- \texttt{x} : a character vector, or an object which can be coerced to a character vector by \texttt{as.character}.
- \texttt{width} : Positive integer values: recycled to the length of \texttt{x}.

**Details**

‘Width’ is interpreted as the display width in a monospaced font. What happens with non-printable characters (such as backspace, tab) is implementation-dependent and may depend on the locale (e.g., they may be included in the count or they may be omitted).

Using this function rather than \texttt{substr} is important when there might be double-width (e.g., Chinese/Japanese/Korean) characters in the character vector.

**Value**

A character vector of the same length and with the same attributes as \texttt{x} (after possible coercion). Elements of the result will have the encoding declared as that of the current locale (see \texttt{Encoding}) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8.

**Examples**

```r
strtrim(c("abcdef", "abcdef", "abcdef"), c(1,5,10))
```
**structure**

**Attribute Specification**

**Description**

`structure` returns the given object with further attributes set.

**Usage**

`structure(.Data, ...)`

**Arguments**

- `.Data` an object which will have various attributes attached to it.
- `...` attributes, specified in `tag = value` form, which will be attached to data.

**Details**

Adding a class "factor" will ensure that numeric codes are given integer storage mode.

For historical reasons (these names are used when deparsing), attributes ".Dim", ".Dimnames", ".Names", ".Tsp" and ".Label" are renamed to "dim", "dimnames", "names", "tsp" and "levels".

It is possible to give the same tag more than once, in which case the last value assigned wins. As with other ways of assigning attributes, using `tag = NULL` removes attribute tag from `.Data` if it is present.

**References**

**See Also**

`attributes, attr`.

**Examples**

`structure(1:6, dim = 2:3)`
**strwrap**

*Wrap Character Strings to Format Paragraphs*

**Description**

Each character string in the input is first split into paragraphs (or lines containing whitespace only). The paragraphs are then formatted by breaking lines at word boundaries. The target columns for wrapping lines and the indentation of the first and all subsequent lines of a paragraph can be controlled independently.

**Usage**

\[
\text{strwrap}(x, \text{width} = 0.9 \times \text{getOption("width")}, \text{indent} = 0, \\
\text{exdent} = 0, \text{prefix} = ",\text{ simplify} = \text{TRUE}, \text{initial} = \text{prefix})
\]

**Arguments**

- **x**: a character vector, or an object which can be converted to a character vector by `as.character`
- **width**: a positive integer giving the target column for wrapping lines in the output.
- **indent**: a non-negative integer giving the indentation of the first line in a paragraph.
- **exdent**: a non-negative integer specifying the indentation of subsequent lines in paragraphs.
- **prefix, initial**: a character string to be used as prefix for each line except the first, for which `initial` is used.
- **simplify**: a logical. If `TRUE`, the result is a single character vector of line text; otherwise, it is a list of the same length as `x` the elements of which are character vectors of line text obtained from the corresponding element of `x`. (Hence, the result in the former case is obtained by unlisting that of the latter.)

**Details**

Whitespace (space, tab or newline characters) in the input is destroyed. Double spaces after periods, question and explanation marks (thought as representing sentence ends) are preserved. Currently, possible sentence ends at line breaks are not considered specially.

Indentation is relative to the number of characters in the prefix string.

**Value**

A character vector (if `simplify` is `TRUE`), or a list of such character vectors, with declared input encodings preserved.

**Examples**

```r
## Read in file 'THANKS'.
x <- paste(readLines(file.path(R.home("doc"), "THANKS")), collapse = "\n")
## Split into paragraphs and remove the first three ones
x <- unlist(strsplit(x, "\n\[ \t\n\]*\n")[-c(1:3)]
## Join the rest
```
x <- paste(x, collapse = "\n\n")
## Now for some fun:
writeLines(strwrap(x, width = 60))
writeLines(strwrap(x, width = 60, indent = 5))
writeLines(strwrap(x, width = 60, exdent = 5))
writeLines(strwrap(x, prefix = "THANKS> "))

## Note that messages are wrapped AT the target column indicated by
## 'width' (and not beyond it).
## From an R-devel posting by J. Hosking <jh910@juno.com>.
x <- paste(sapply(sample(10, 100, replace = TRUE),
    function(x) substring("aaaaaaaaaa", 1, x)), collapse = " ")
sapply(10:40,
    function(m)
    c(target = m, actual = max(nchar(strwrap(x, m)))))

subset

Subsetting Vectors, Matrices and Data Frames

Description

Return subsets of vectors, matrices or data frames which meet conditions.

Usage

subset(x, ...)

## Default S3 method:
subset(x, subset, ...)

## S3 method for class 'matrix'
subset(x, subset, select, drop = FALSE, ...)

## S3 method for class 'data.frame'
subset(x, subset, select, drop = FALSE, ...)

Arguments

x

object to be subsetted.

subset

logical expression indicating elements or rows to keep: missing values are taken as false.

select

expression, indicating columns to select from a data frame.

drop

passed on to [ indexing operator.

...

further arguments to be passed to or from other methods.

Details

This is a generic function, with methods supplied for matrices, data frames and vectors (including lists). Packages and users can add further methods.

For ordinary vectors, the result is simply x[subset & !is.na(subset)].
For data frames, the `subset` argument works on the rows. Note that `subset` will be evaluated in the data frame, so columns can be referred to (by name) as variables in the expression (see the examples).

The `select` argument exists only for the methods for data frames and matrices. It works by first replacing column names in the selection expression with the corresponding column numbers in the data frame and then using the resulting integer vector to index the columns. This allows the use of the standard indexing conventions so that for example ranges of columns can be specified easily, or single columns can be dropped (see the examples).

The `drop` argument is passed on to the indexing method for matrices and data frames: note that the default for matrices is different from that for indexing.

Factors may have empty levels after subsetting; unused levels are not automatically removed. See `droplevels` for a way to drop all unused levels from a data frame.

Value

An object similar to `x` contain just the selected elements (for a vector), rows and columns (for a matrix or data frame), and so on.

Warning

This is a convenience function intended for use interactively. For programming it is better to use the standard subsetting functions like `[`, and in particular the non-standard evaluation of argument `subset` can have unanticipated consequences.

Author(s)

Peter Dalgaard and Brian Ripley

See Also

`[`, `transform`, `droplevels`

Examples

```r
subset(airquality, Temp > 80, select = c(Ozone, Temp))
subset(airquality, Day == 1, select = -Temp)
subset(airquality, select = Ozone:Wind)
with(airquality, subset(Ozone, Temp > 80))
```

```r
## sometimes requiring a logical 'subset' argument is a nuisance
nm <- rownames(state.x77)
start_with_M <- nm %in% grep("^M", nm, value = TRUE)
subset(state.x77, start_with_M, Illiteracy:Murder)
# but in recent versions of R this can simply be
subset(state.x77, grepl("^M", nm), Illiteracy:Murder)
```
substitute

Substituting and Quoting Expressions

Description

substitute returns the parse tree for the (unevaluated) expression expr, substituting any variables bound in env.

quote simply returns its argument. The argument is not evaluated and can be any R expression.

enquote is a simple one-line utility which transforms a call of the form Foo(...) into the call quote(Foo(...)). This is typically used to protect a call from early evaluation.

Usage

substitute(expr, env)
quote(expr)
enquote(cl)

Arguments

expr any syntactically valid R expression
cl a call, i.e., an R object of class (and mode) "call".
env an environment or a list object. Defaults to the current evaluation environment.

Details

The typical use of substitute is to create informative labels for data sets and plots. The myplot example below shows a simple use of this facility. It uses the functions deparse and substitute to create labels for a plot which are character string versions of the actual arguments to the function myplot.

Substitution takes place by examining each component of the parse tree as follows: If it is not a bound symbol in env, it is unchanged. If it is a promise object, i.e., a formal argument to a function or explicitly created using delayedAssign(), the expression slot of the promise replaces the symbol. If it is an ordinary variable, its value is substituted, unless env is .GlobalEnv in which case the symbol is left unchanged.

Both quote and substitute are 'special' primitive functions which do not evaluate their arguments.

Value

The mode of the result is generally "call" but may in principle be any type. In particular, single-variable expressions have mode "name" and constants have the appropriate base mode.

Note

substitute works on a purely lexical basis. There is no guarantee that the resulting expression makes any sense.

Substituting and quoting often cause confusion when the argument is expression(...). The result is a call to the expression constructor function and needs to be evaluated with eval to give the actual expression object.
References

See Also

`missing` for argument ‘missingness’, `bquote` for partial substitution, `sQuote` and `dQuote` for adding quotation marks to strings, `all.names` to retrieve the symbol names from an expression or call.

Examples

```r
require(graphics)
(s.e <- substitute(expression(a + b), list(a = 1))) #> expression(1 + b)
(s.s <- substitute( a + b, list(a = 1))) #> 1 + b
c(mode(s.e), typeof(s.e)) # "call", "language"
c(mode(s.s), typeof(s.s)) # (the same)
# but:
(e.s.e <- eval(s.e)) #> expression(1 + b)
c(mode(e.s.e), typeof(e.s.e)) # "expression", "expression"

substr(x <- x + 1, list(x = 1)) # nonsense

myplot <- function(x, y)
  plot(x, y, xlab = deparse(substitute(x)),
       ylab = deparse(substitute(y)))

## Simple examples about lazy evaluation, etc:

f1 <- function(x, y = x) { x <- x + 1; y }
s1 <- function(x, y = substitute(x)) { x <- x + 1; y }
s2 <- function(x, y) { if(missing(y)) y <- substitute(x); x <- x + 1; y }
a <- 10
f1(a) # 11
s1(a) # 11
s2(a) # a
typeof(s2(a)) # "symbol"
```

### substr

**Substrings of a Character Vector**

**Description**

Extract or replace substrings in a character vector.

**Usage**

```r
substr(x, start, stop)
substring(text, first, last = 1000000L)
substr(x, start, stop) <- value
substring(text, first, last = 1000000L) <- value
```
Arguments

- **x, text**: a character vector.
- **start, first**: integer. The first element to be replaced.
- **stop, last**: integer. The last element to be replaced.
- **value**: a character vector, recycled if necessary.

Details

substring is compatible with S, with first and last instead of start and stop. For vector arguments, it expands the arguments cyclically to the length of the longest provided none are of zero length.

When extracting, if start is larger than the string length then "" is returned.

For the extraction functions, x or text will be converted to a character vector by `as.character` if it is not already one.

For the replacement functions, if start is larger than the string length then no replacement is done.

If the portion to be replaced is longer than the replacement string, then only the portion the length of the string is replaced.

If any argument is an NA element, the corresponding element of the answer is NA.

Elements of the result will be have the encoding declared as that of the current locale (see `Encoding` if the corresponding input had a declared Latin-1 or UTF-8 encoding and the current locale is either Latin-1 or UTF-8.

If an input element has declared "bytes" encoding (see `Encoding`, the subsetting is done in units of bytes not characters.

Value

For substr, a character vector of the same length and with the same attributes as x (after possible coercion).

For substring, a character vector of length the longest of the arguments. This will have names taken from x (if it has any after coercion, repeated as needed), and other attributes copied from x if it is the longest of the arguments).

Elements of x with a declared encoding (see `Encoding`) will be returned with the same encoding.

Note

The S4 version of substrings<- ignores last; this version does not.

These functions are often used with nchar to truncate a display. That does not really work (you want to limit the width, not the number of characters, so it would be better to use `strtrim`), but at least make sure you use the default nchar(type = "c").

References

See Also

`strsplit, paste, nchar`. 

**sum**

**Examples**

```r
substr("abcdef", 2, 4)
substring("abcdef", 1:6, 1:6)
## strsplit is more efficient ...
substr(rep("abcdef", 4), 1:4, 4:5)
```

```r
x <- c("asfef", "qwerty", "yuiop[", "b", "stuff.blah.yech")
substr(x, 2, 5)
substring(x, 2, 4:6)
```

```r
substring(x, 2) <- c("..", "+++")
x
```

**Description**

`sum` returns the sum of all the values present in its arguments.

**Usage**

```r
sum(..., na.rm = FALSE)
```

**Arguments**

- `...`: numeric or complex or logical vectors.
- `na.rm`: logical. Should missing values (including NaN) be removed?

**Details**

This is a generic function: methods can be defined for it directly or via the `Summary` group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

If `na.rm` is `FALSE` an `NA` or `NaN` value in any of the arguments will cause a value of `NA` or `NaN` to be returned, otherwise `NA` and `NaN` values are ignored.

Logical true values are regarded as one, false values as zero. For historical reasons, `NULL` is accepted and treated as if it were `integer(0)`.

Loss of accuracy can occur when summing values of different signs: this can even occur for sufficiently long integer inputs if the partial sums would cause integer overflow. Where possible extended-precision accumulators are used, but this is platform-dependent.

**Value**

The sum. If all of `...` are of type integer or logical, then the sum is integer, and in that case the result will be `NA` (with a warning) if integer overflow occurs. Otherwise it is a length-one numeric or complex vector.

**NB:** the sum of an empty set is zero, by definition.
S4 methods

This is part of the S4 Summary group generic. Methods for it must use the signature x, ..., na.rm.

‘plotmath’ for the use of sum in plot annotation.

References

See Also

colSums for row and column sums.

Examples

## Pass a vector to sum, and it will add the elements together.
sum(1:5)

## Pass several numbers to sum, and it also adds the elements.
sum(1, 2, 3, 4, 5)

## In fact, you can pass vectors into several arguments, and everything gets added.
sum(1:2, 3:5)

## If there are missing values, the sum is unknown, i.e., also missing, ....
sum(1:5, NA)

## ... unless we exclude missing values explicitly:
sum(1:5, NA, na.rm = TRUE)

summary Object Summaries

Description

summary is a generic function used to produce result summaries of the results of various model fitting functions. The function invokes particular methods which depend on the class of the first argument.

Usage

summary(object, ...)

## Default S3 method:
summary(object, ..., digits)

## S3 method for class 'data.frame'
summary(object, maxsum = 7, digits = max(3, getOption("digits")-3), ...)

## S3 method for class 'factor'
summary(object, maxsum = 100, ...)

## S3 method for class 'matrix'
### Arguments

- **object**: an object for which a summary is desired.
- **x**: a result of the `default` method of `summary()`.
- **maxsum**: integer, indicating how many levels should be shown for factors.
- **digits**: integer, used for number formatting with `signif()` (for `summary.default`) or `format()` (for `summary.data.frame`). In `summary.default`, if not specified (i.e., `missing()`), `signif()` will not be called anymore (since R >= 3.4.0, where the default has been changed to only round in the print and format methods).
- **...**: additional arguments affecting the summary produced.

### Details

For factors, the frequency of the first `maxsum - 1` most frequent levels is shown, and the less frequent levels are summarized in "(Others)" (resulting in at most `maxsum` frequencies).

The functions `summary.lm` and `summary.glm` are examples of particular methods which summarize the results produced by `lm` and `glm`.

### Value

The form of the value returned by `summary` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

The default method returns an object of class `c("summaryDefault", "table")` which has specialized `format` and `print` methods. The `factor` method returns an integer vector.

The matrix and data frame methods return a matrix of class "table", obtained by applying `summary` to each column and collating the results.

### References

### See Also

`anova`, `summary.glm`, `summary.lm`.

### Examples

```r
summary(attenu, digits = 4) #-> summary.data.frame(...), default precision
summary(attenu$station, maxsum = 20) #-> summary.factor(...)

lst <- unclass(attenu$station) > 20 # logical with NAs
## summary.default() for logicals -- different from *.factor:
summary(lst)
summary(as.factor(lst))
```
Singular Value Decomposition of a Matrix

Description
Compute the singular-value decomposition of a rectangular matrix.

Usage
```r
svd(x, nu = min(n, p), nv = min(n, p), LINPACK = FALSE)
La.svd(x, nu = min(n, p), nv = min(n, p))
```

Arguments
- **x**: a numeric or complex matrix whose SVD decomposition is to be computed. Logical matrices are coerced to numeric.
- **nu**: the number of left singular vectors to be computed. This must be between 0 and \( n = \text{nrow}(x) \).
- **nv**: the number of right singular vectors to be computed. This must be between 0 and \( p = \text{ncol}(x) \).
- **LINPACK**: logical. Defunct and ignored.

Details
The singular value decomposition plays an important role in many statistical techniques. `svd` and `La.svd` provide two interfaces which differ in their return values.

Computing the singular vectors is the slow part for large matrices. The computation will be more efficient if both \( nu \leq \min(n, p) \) and \( nv \leq \min(n, p) \), and even more so if both are zero.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code (most often 1): these can only be interpreted by detailed study of the FORTRAN code but mean that the algorithm failed to converge.

Value
The SVD decomposition of the matrix as computed by LAPACK,

\[
X = UDV',
\]

where \( U \) and \( V \) are orthogonal, \( V' \) means \( V \) transposed (and conjugated for complex input), and \( D \) is a diagonal matrix with the singular values \( D_{ii} \). Equivalently, \( D = U'XV \), which is verified in the examples.

The returned value is a list with components
- **d**: a vector containing the singular values of \( x \), of length \( \min(n, p) \).
- **u**: a matrix whose columns contain the left singular vectors of \( x \), present if \( nu > 0 \). Dimension \( c(n, nu) \).
- **v**: a matrix whose columns contain the right singular vectors of \( x \), present if \( nv > 0 \). Dimension \( c(p, nv) \).
Recall that the singular vectors are only defined up to sign (a constant of modulus one in the complex case). If a left singular vector has its sign changed, changing the sign of the corresponding right vector gives an equivalent decomposition.

For `la.svd` the return value replaces `v` by `vt`, the (conjugated if complex) transpose of `v`.

**Source**

The main functions used are the LAPACK routines DGESDD and ZGESDD.

LAPACK is from [http://www.netlib.org/lapack](http://www.netlib.org/lapack) and its guide is listed in the references.

**References**

**See Also**

eigen, qr.

**Examples**

```r
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "*") }
X <- hilbert(9)[, 1:6]
(s <- svd(X))
D <- diag(s$d)
s$u %*% D %*% t(s$v) # X = U D V'
t(s$u) %*% X %*% s$v # D = U' X V
```

**sweep**  
Sweep out Array Summaries

**Description**

Return an array obtained from an input array by sweeping out a summary statistic.

**Usage**

`sweep(x, MARGIN, STATS, FUN = "+", check.margin = TRUE, ...)`

**Arguments**

- `x`: an array.
- `MARGIN`: a vector of indices giving the extent(s) of `x` which correspond to `STATS`.
- `STATS`: the summary statistic which is to be swept out.
- `FUN`: the function to be used to carry out the sweep.
- `check.margin`: logical. If TRUE (the default), warn if the length or dimensions of `STATS` do not match the specified dimensions of `x`. Set to FALSE for a small speed gain when you know that dimensions match.
- `...`: optional arguments to `FUN`. 
Details

FUN is found by a call to `match.fun`. As in the default, binary operators can be supplied if quoted or backquoted.

FUN should be a function of two arguments: it will be called with arguments x and an array of the same dimensions generated from STATS by `aperm`.

The consistency check among STATS, MARGIN and x is stricter if STATS is an array than if it is a vector. In the vector case, some kinds of recycling are allowed without a warning. Use `sweep(x, MARGIN, as.array(STATS))` if STATS is a vector and you want to be warned if any recycling occurs.

Value

An array with the same shape as x, but with the summary statistics swept out.

References

See Also

`apply` on which `sweep` used to be based; `scale` for centering and scaling.

Examples

```r
require(stats) # for median
med.att <- apply(attitude, 2, median)
sweep(data.matrix(attitude), 2, med.att) # subtract the column medians

## More sweeping:
A <- array(1:24, dim = 4:2)

## no warnings in normal use
sweep(A, 1, 5)
(A.min <- apply(A, 1, min)) # == 1:4
sweep(A, 1, A.min)
sweep(A, 1:2, apply(A, 1:2, median))

## warnings when mismatch
sweep(A, 1, 1:3) # STATS does not recycle
sweep(A, 1, 6:1) # STATS is longer

## exact recycling:
sweep(A, 1, 1:2) # no warning
sweep(A, 1, as.array(1:2)) # warning
```

switch

Select One of a List of Alternatives

Description

`switch` evaluates `EXPR` and accordingly chooses one of the further arguments (in . . .).
**switch**

**Usage**

```
switch(EXPR, ...
```

**Arguments**

**EXPR**

an expression evaluating to a number or a character string.

**...**

the list of alternatives. If it is intended that **EXPR** has a character-string value these will be named, perhaps except for one alternative to be used as a ‘default’ value.

**Details**

`switch` works in two distinct ways depending whether the first argument evaluates to a character string or a number.

If the value of **EXPR** is not a character string it is coerced to integer. Note that this also happens for `factor`s, with a warning, as typically the character level is meant. If the integer is between 1 and `nargs()`-1 then the corresponding element of `...` is evaluated and the result returned: thus if the first argument is 3 then the fourth argument is evaluated and returned.

If **EXPR** evaluates to a character string then that string is matched (exactly) to the names of the elements in `...`. If there is a match then that element is evaluated unless it is missing, in which case the next non-missing element is evaluated, so for example `switch("cc", a = 1, cc =, cd =, d = 2)` evaluates to 2. If there is more than one match, the first matching element is used. In the case of no match, if there is a unnamed element of `...` its value is returned. (If there is more than one such argument an error is signaled.)

The first argument is always taken to be **EXPR**: if it is named its name must (partially) match.

A warning is signaled if no alternatives are provides, as this is usually a coding error.

This is implemented as a **primitive** function that only evaluates its first argument and one other if one is selected.

**Value**

The value of one of the elements of `...` or **NULL**, invisibly (whenever no element is selected).

The result has the visibility (see **invisible**) of the element evaluated.

**Warning**

It is possible to write calls to `switch` that can be confusing and may not work in the same way in earlier versions of **R**. For compatibility (and clarity), always have **EXPR** as the first argument, naming it if partial matching is a possibility. For the character-string form, have a single unnamed argument as the default after the named values.

**References**

Syntax

Examples

```r
require(stats)
centre <- function(x, type) {
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
centre(x, "mean")
centre(x, "median")
centre(x, "trimmed")

ccc <- c("b","QQ","a","A","bb")
# note: cat() produces no output for NULL
for(ch in ccc)
  cat(ch,":", switch(EXPR = ch, a = 1, b = 2:3), "\n")
for(ch in ccc)
  cat(ch,":", switch(EXPR = ch, a =, A = 1, b = 2:3, "Otherwise: last"),"\n")

## switch(f, *) with a factor f
ff <- gl(3,1, labels=LETTERS[3:1])
ff[1] # C
## so one might expect " is C" here, but
switch(ff[1], A = "I am A", B="Bb..", C=" is C")# -> "I am A"
## so we give a warning
## Numeric EXPR does not allow a default value to be specified
## -- it is always NULL
for(i in c(-1:3, 9)) print(switch(i, 1, 2, 3, 4))

## visibility
switch(1, invisible(pi), pi)
switch(2, invisible(pi), pi)
```

Description

Outlines R syntax and gives the precedence of operators.

Details

The following unary and binary operators are defined. They are listed in precedence groups, from highest to lowest.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>:: :: ::</td>
<td>access variables in a namespace</td>
</tr>
<tr>
<td>$ @</td>
<td>component / slot extraction</td>
</tr>
<tr>
<td>[ []</td>
<td>indexing</td>
</tr>
<tr>
<td>^</td>
<td>exponentiation (right to left)</td>
</tr>
<tr>
<td>- +</td>
<td>unary minus and plus</td>
</tr>
<tr>
<td>:</td>
<td>sequence operator</td>
</tr>
</tbody>
</table>
Syntax

special operators (including % and %/%)
multiply, divide
(binary) add, subtract
ordering and comparison
negation
and
or
as in formulae
rightwards assignment
assignment (right to left)
assignment (right to left)
help (unary and binary)

Within an expression operators of equal precedence are evaluated from left to right except where indicated. (Note that = is not necessarily an operator.)
The binary operators ::, :::, $ and @ require names or string constants on the right hand side, and the first two also require them on the left.

The links in the See Also section cover most other aspects of the basic syntax.

Note

There are substantial precedence differences between R and S. In particular, in S ? has the same precedence as (binary) + - and & & | || have equal precedence.

References

See Also

Arithmetic, Comparison, Control, Extract, Logic, NumericConstants, Paren, Quotes, Reserved.

The ‘R Language Definition’ manual.

Examples

## Logical AND ("&&") has higher precedence than OR ("||"):
TRUE || TRUE && FALSE  # is the same as
TRUE || (TRUE && FALSE) # and different from
(TRUE || TRUE) && FALSE

## Special operators have higher precedence than "!" (logical NOT).
# You can use this for %in% :
! 1:10 %in% c(2, 3, 5, 7) # same as !(1:10 %in% c(2, 3, 5, 7))
## but we strongly advise to use the "!( ... )" form in this case!

## '=' has lower precedence than '<=' ... so you should not mix them
## (and '<=' is considered better style anyway):
## Consequently, this gives a ("non-catchable") error
x <- y = 5  #=> Error in (x <- y) = 5 : ....
Sys.getenv

Get Environment Variables

Description

Sys.getenv obtains the values of the environment variables.

Usage

Sys.getenv(x = NULL, unset = "", names = NA)

Arguments

x  a character vector, or NULL.
unset  a character string.
names  logical: should the result be named? If NA (the default) single-element results are not named whereas multi-element results are.

Details

Both arguments will be coerced to character if necessary.

Setting unset = NA will enable unset variables and those set to the value "" to be distinguished, if the OS does. POSIX requires the OS to distinguish, and all known current R platforms do.

Value

A vector of the same length as x, with (if names == TRUE) the variable names as its names attribute. Each element holds the value of the environment variable named by the corresponding component of x (or the value of unset if no environment variable with that name was found).

On most platforms Sys.getenv() will return a named vector giving the values of all the environment variables, sorted in the current locale. It may be confused by names containing = which some platforms allow but POSIX does not. (Windows is such a platform: there names including = are truncated just before the first =.)

When x is missing and names is not false, the result is of class "Dlist" in order to get a nice print method.

See Also

Sys.setenv, Sys.getlocale for the locale in use, getwd for the working directory.

The help for 'environment variables' lists many of the environment variables used by R.

Examples

## whether HOST is set will be shell-dependent e.g. Solaris' csh does not.
Sys.getenv(c("R_HOME", "R_PAPERSIZE", "R_PRINTCMD", "HOST"))

names(s <- Sys.getenv()) # all settings (the values could be very long)
head(s, 12)# using the Dlist print() method

## Language and Locale settings -- but rather use Sys.getlocale()
s[grep("L(C|ANG)", names(s))]
Sys.getpid  Get the Process ID of the R Session

Description
Get the process ID of the R Session. It is guaranteed by the operating system that two R sessions running simultaneously will have different IDs, but it is possible that R sessions running at different times will have the same ID.

Usage
Sys.getpid()

Value
An integer, often between 1 and 32767 under Unix-alikes (but for example FreeBSD and macOS use IDs up to 99999) and a positive integer (up to 32767) under Windows.

Examples
Sys.getpid()

## Show files opened from this R process
if(.Platform$OS.type == "unix") ## on Unix-alikes such Linux, macOS, FreeBSD:
  system(paste("lsof -p", Sys.getpid()))

Sys.glob  Wildcard Expansion on File Paths

Description
Function to do wildcard expansion (also known as 'globbing') on file paths.

Usage
Sys.glob(paths, dirmark = FALSE)

Arguments
paths character vector of patterns for relative or absolute filepaths. Missing values will be ignored.
dirmark logical: should matches to directories from patterns that do not already end in / have a slash appended? May not be supported on all platforms.
Details

This expands wildcards in file paths. For precise details, see your system’s documentation on the glob system call. There is a POSIX 1003.2 standard (see http://pubs.opengroup.org/onlinepubs/9699919799/functions/glob.html) but some OSes will go beyond this. The R implementation will always do tilde expansion.

All systems should interpret * (match zero or more characters), ? (match a single character) and (probably) [ (begin a character class or range). The handling of paths ending with a separator is system-dependent. On a POSIX-2008 compliant OS they will match directories (only), but as they are not valid filepaths on Windows, they match nothing there. (Earlier POSIX standards allowed them to match files.)

The rest of these details are indicative (and based on the POSIX standard).

If a filename starts with . this may need to be matched explicitly: for example Sys.glob("*.RData") may or may not match `.RData’ but will not usually match `.aa.RData’.

Note that this is platform-dependent: e.g. on Solaris Sys.glob("*.S") matches ‘.’ and ‘.’.

[ begins a character class. If the first character in [...] is not !, this is a character class which matches a single character against any of the characters specified. The class cannot be empty, so ] can be included provided it is first. If the first character is !, the character class matches a single character which is none of the specified characters. Whether . in a character class matches a leading . in the filename is OS-dependent.

Character classes can include ranges such as [A-Z]: include − as a character by having it first or last in a class. (The interpretation of ranges should be locale-specific, so the example is not a good idea in an Estonian locale.)

One can remove the special meaning of ?, * and [ by preceding them by a backslash (except within a character class).

Value

A character vector of matched file paths. The order is system-specific (but in the order of the elements of paths): it is normally collated in either the current locale or in byte (ASCII) order; however, on Windows collation is in the order of Unicode points.

Directory errors are normally ignored, so the matches are to accessible file paths (but not necessarily accessible files).

See Also

path.expand.

Quotes for handling backslashes in character strings.

Examples

Sys.glob(file.path(R.home(), "library", "*", "R", "*.rdx"))
Description

Reports system and user information.

Usage

Sys.info()

Details

This uses POSIX or Windows system calls. Note that OS names might not be what you expect: for example macOS identifies itself as ‘Darwin’ and Solaris as ‘SunOS’.

Sys.info() returns details of the platform \texttt{R} is running on, whereas \texttt{R.version} gives details of the platform \texttt{R} was built on: the release and version may well be different.

Value

A character vector with fields

\begin{itemize}
\item \texttt{sysname} The operating system name.
\item \texttt{release} The OS release.
\item \texttt{version} The OS version.
\item \texttt{nodename} A name by which the machine is known on the network (if any).
\item \texttt{machine} A concise description of the hardware, often the CPU type.
\item \texttt{login} The user’s login name, or "unknown" if it cannot be ascertained.
\item \texttt{user} The name of the real user ID, or "unknown" if it cannot be ascertained. This may differ from the real user in ‘set-user-ID’ processes.
\item \texttt{effective_user} The name of the effective user ID, or "unknown" if it cannot be ascertained. This may differ from the real user in ‘set-user-ID’ processes.
\end{itemize}

The first five fields come from the \texttt{uname(2)} system call. The login name comes from \texttt{getlogin(2)}, and the user names from \texttt{getpwuid(getuid())} and \texttt{getpwuid(geteuid())}

Note

The meaning of release and version is system-dependent: on a Unix-alike they normally refer to the kernel. There, usually release contains a numeric version and version gives additional information. Examples for release:

\begin{itemize}
\item "4.1.3-100.fc21.x86_64" # Linux (Fedora)
\item "3.2.0-4-amd64" # Linux (Debian)
\item "14.5.0" # macOS 10.10.5
\item "5.11" # Solaris
\end{itemize}

There is no guarantee that the node or login or user names will be what you might reasonably expect. (In particular on some Linux distributions the login name is unknown from sessions with re-directed inputs.)

The use of alternatives such as \texttt{system("whoami")} is not portable: the POSIX command \texttt{system("id")} is much more portable on Unix-alikes, provided only the POSIX options are used (and not the many BSD and GNU extensions).
See Also

`.Platform`, and `R.version`. `sessionInfo()` gives a synopsis of both your system and the R session (and gives the OS version in a human-readable form).

Examples

```r
Sys.info()
## An alternative (and probably better) way to get the login name on Unix
Sys.getenv("LOGNAME")
```

### Sys.localeconv

Find Details of the Numerical and Monetary Representations in the Current Locale

**Description**

Get details of the numerical and monetary representations in the current locale.

**Usage**

```r
Sys.localeconv()
```

**Details**

Normally R is run without looking at the value of `LC_NUMERIC`, so the decimal point remains `.`. So the first three of these components will only be useful if you have set the locale category `LC_NUMERIC` using `Sys.setlocale` in the current R session (when R may not work correctly). The monetary components will only be set to non-default values (see the ‘Examples’ section if the `LC_MONETARY` category is set. It often is not set: set the examples for how to trigger setting it.

**Value**

A character vector with 18 named components. See your ISO C documentation for details of the meaning.

It is possible to compile R without support for locales, in which case the value will be `NULL`.

**See Also**

`Sys.setlocale` for ways to set locales.

**Examples**

```r
Sys.localeconv()
## The results in the C locale are
## decimal_point thousands_sep grouping int_curr_symbol
## "." "" ""
## currency_symbol mon_decimal_point mon_thousands_sep mon_grouping
## "" "" ""
## positive_sign negative_sign int_frac_digits frac_digits
## "" "" "" ""127" "127"
## p_cs_precedes p_sep_by_space n_cs_precedes n_sep_by_space
## "127" "127" "127" "127"
```
## p_sign_posn  n_sign_posn
## "127"     "127"

## Now try your default locale (which might be "C").
old <- Sys.getlocale()
## The category may not be set:
## the following may do so, but it might not be supported.
Sys.setlocale("LC_MONETARY", locale = "")
Sys.localeconv()
## or set an appropriate value yourself, e.g.
Sys.setlocale("LC_MONETARY", "de_AT")
Sys.localeconv()
Sys.setlocale(locale = old)

## Not run: read.table("foo", dec=Sys.localeconv()["decimal_point"])

---

### Functions to Access the Function Call Stack

**Description**

These functions provide access to environments (‘frames’ in S terminology) associated with functions further up the calling stack.

**Usage**

```r
sys.call(which = 0)
sys.frame(which = 0)
sys.nframe()
sys.function(which = 0)
sys.parent(n = 1)

sys.calls()
sys.frames()
sys.parents()
sys.on.exit()
sys.status()
parent.frame(n = 1)
```

**Arguments**

- `which` the frame number if non-negative, the number of frames to go back if negative.
- `n` the number of generations to go back. (See the ‘Details’ section.)

**Details**

`.GlobalEnv` is given number 0 in the list of frames. Each subsequent function evaluation increases the frame stack by 1 and the call, function definition and the environment for evaluation of that function are returned by `sys.call`, `sys.function` and `sys.frame` with the appropriate index. `sys.call`, `sys.frame` and `sys.function` accept integer values for the argument which. Non-negative values of which are frame numbers whereas negative values are counted back from the frame number of the current evaluation.
The parent frame of a function evaluation is the environment in which the function was called. It is not necessarily numbered one less than the frame number of the current evaluation, nor is it the environment within which the function was defined. `sys.parent` returns the number of the parent frame if \( n = 1 \) (the default), the grandparent if \( n = 2 \), and so on. See also the ‘Note’.

`sys.nframe` returns an integer, the number of the current frame as described in the first paragraph.

`sys.calls` and `sys.frames` give a pair list of all the active calls and frames, respectively, and `sys.parents` returns an integer vector of indices of the parent frames of each of those frames.

Notice that even though the `sys.xxx` functions (except `sys.status`) are interpreted, their contexts are not counted nor are they reported. There is no access to them.

`sys.status()` returns a list with components `sys.calls`, `sys.parents` and `sys.frames`, the results of calls to those three functions (which this will include the call to `sys.status`: see the first example).

`sys.on.exit()` returns the expression stored for use by `on.exit` in the function currently being evaluated. (Note that this differs from S, which returns a list of expressions for the current frame and its parents.)

`parent.frame(n)` is a convenient shorthand for `sys.frame(sys.parent(n))` (implemented slightly more efficiently).

Value

`sys.call` returns a call, `sys.function` a function definition, and `sys.frame` and `parent.frame` return an environment.

For the other functions, see the ‘Details’ section.

Note

Strictly, `sys.parent` and `parent.frame` refer to the context of the parent interpreted function. So internal functions (which may or may not set contexts and so may or may not appear on the call stack) may not be counted, and S3 methods can also do surprising things.

Beware of the effect of lazy evaluation: these two functions look at the call stack at the time they are evaluated, not at the time they are called. Passing calls to them as function arguments is unlikely to be a good idea.

References

See Also

`eval` for a usage of `sys.frame` and `parent.frame`.

Examples

```r
require(utils)

## Note: the first two examples will give different results
## if run by example()
ff <- function(x) gg(x)
gg <- function(y) sys.status()
str(ff(1))
```
Sys.readlink

Sys.readlink

Read File Symbolic Links

Description

Find out if a file path is a symbolic link, and if so what it is linked to, via the system call readlink.
Symbolic links are a POSIX concept, not implemented on Windows but for most filesystems on Unix-alikes.

Usage

Sys.readlink(paths)

Arguments

paths character vector of file paths. Tilde expansion is done: see path.expand.

Value

A character vector of the same length as paths. The entries are the path of the file linked to, "" if the path is not a symbolic link, and NA if there is an error (e.g., the path does not exist).

On platforms without the readlink system call, all elements are "".

See Also

c file.symlink for the creation of symbolic links (and their Windows analogues), file.info

Sys.setenv

Set or Unset Environment Variables

Description

Sys.setenv sets environment variables (for other processes called from within R or future calls to
Sys.getenv from this R process).
Sys.unsetenv removes environment variables.

Usage

Sys.setenv(...)  
Sys.unsetenv(x)

Arguments

... named arguments with values coercible to a character string.

x a character vector, or an object coercible to character.

Details

Non-standard R names must be quoted in Sys.setenv: see the examples. Most platforms (and POSIX) do not allow names containing "=". Windows does, but the facilities provided by R may not handle these correctly so they should be avoided. Most platforms allow setting an environment variable to "", but Windows does not, and there Sys.setenv(F00 = "") unsets F00.

There may be system-specific limits on the maximum length of the values of individual environment variables or of all environment variables.
Value

A logical vector, with elements being true if (un)setting the corresponding variable succeeded. (For `Sys.unsetenv` this includes attempting to remove a non-existent variable.)

Note

If `Sys.unsetenv` is not supported, it will at least try to set the value of the environment variable to "", with a warning.

See Also

`Sys.getenv`, `Startup` for ways to set environment variables for the R session.

`setwd` for the working directory.

The help for ‘environment variables’ lists many of the environment variables used by R.

Examples

```r
print(Sys.setenv(R_TEST = "testit", "A+C" = 123))  # `A+C` could also be used
Sys.getenv("R_TEST")
Sys.unsetenv("R_TEST")  # may warn and not succeed
Sys.getenv("R_TEST", unset = NA)
```

### Sys.setFileTime

#### Description

Uses system calls to set the times on a file or directory.

#### Usage

```r
Sys.setFileTime(path, time)
```

#### Arguments

- **path**: A length-one character vector specifying the path to a file or directory.
- **time**: A date-time of class "POSIXct" or an object which can be coerced to one. Fractions of a second may be ignored.

#### Details

This attempts sets the file time to the value specified.

On a Unix-alike it uses the system call `utimensat` if that is available, otherwise `utimes` or `utime`. On a POSIX file system it sets both the last-access and modification times. Fractional seconds will set as from R 3.4.0 on OSes with the requisite system calls and suitable filesystems.

On Windows it uses the system call `SetFileTime` to set the ‘last write time’. Some Windows file systems only record the time at a resolution of two seconds.

#### Value

Logical, invisibly. An indication if the operation succeeded.
Sys.sleep

Suspend Execution for a Time Interval

Description

Suspend execution of \texttt{R} expressions for a specified time interval.

Usage

\texttt{Sys.sleep(time)}

Arguments

time \hspace{1em} The time interval to suspend execution for, in seconds.

Details

Using this function allows \texttt{R} to temporarily be given very low priority and hence not to interfere with more important foreground tasks. A typical use is to allow a process launched from \texttt{R} to set itself up and read its input files before \texttt{R} execution is resumed.

The intention is that this function suspends execution of \texttt{R} expressions but wakes the process up often enough to respond to GUI events, typically every half second. It can be interrupted (e.g. by ‘\texttt{Ctrl-C}’ or ‘\texttt{Esc}’ at the \texttt{R} console).

There is no guarantee that the process will sleep for the whole of the specified interval (sleep might be interrupted), and it may well take slightly longer in real time to resume execution.

time must be non-negative (and not \texttt{NA} nor \texttt{NaN}): \texttt{Inf} is allowed (and might be appropriate if the intention is to wait indefinitely for an interrupt). The resolution of the time interval is system-dependent, but will normally be 20ms or better. (On modern Unix-alikes it will be better than 1ms.)

Value

Invisible \texttt{NULL}.

Note

Despite its name, this is not currently implemented using the \texttt{sleep} system call (although on Windows it does make use of \texttt{Sleep}).

Examples

\begin{verbatim}
  testit <- function(x)
  {
    p1 <- proc.time()
    Sys.sleep(x)
    proc.time() - p1 \# The cpu usage should be negligible
  }
testit(3.7)
\end{verbatim}
sys.source  Parse and Evaluate Expressions from a File

**Description**

Parses expressions in the given file, and then successively evaluates them in the specified environment.

**Usage**

```r
sys.source(file, envir = baseenv(), chdir = FALSE,
keep.source = getOption("keep.source.pkgs"),
toplevel.env = as.environment(envir))
```

**Arguments**

- `file` a character string naming the file to be read from
- `envir` an R object specifying the environment in which the expressions are to be evaluated. May also be a list or an integer. The default value NULL corresponds to evaluation in the base environment. This is probably not what you want; you should typically supply an explicit envir argument.
- `chdir` logical; if TRUE, the R working directory is changed to the directory containing file for evaluating.
- `keep.source` logical. If TRUE, functions keep their source including comments, see `options(keep.source = *)` for more details.
- `toplevel.env` an R environment to be used as top level while evaluating the expressions. This argument is useful for frameworks running package tests; the default should be used in other cases

**Details**

For large files, `keep.source = FALSE` may save quite a bit of memory.

In order for the code being evaluated to use the correct environment (for example, in global assignments), source code in packages should call `topenv()`, which will return the namespace, if any, the environment set up by `sys.source`, or the global environment if a saved image is being used.

**See Also**

`source`, and `library` which uses `sys.source`.

**Examples**

```r
## a simple way to put some objects in an environment
## high on the search path
tmp <- tempfile()
writeLines("aaa <- pi", tmp)
env <- attach(NULL, name = "myenv")
sys.source(tmp, env)
unlink(tmp)
search()
aaa
detach("myenv")
```
**Sys.time**

**Get Current Date and Time**

**Description**

Sys.time and Sys.Date returns the system's idea of the current date with and without time.

**Usage**

```r
Sys.time()
Sys.Date()
```

**Details**

Sys.time returns an absolute date-time value which can be converted to various time zones and may return different days.

Sys.Date returns the current day in the current time zone.

**Value**

Sys.time returns an object of class "POSIXct" (see DateTimeClasses). On almost all systems it will have sub-second accuracy, possibly microseconds or better. On Windows it increments in clock ticks (usually 1/60 of a second) reported to millisecond accuracy.

Sys.Date returns an object of class "Date" (see Date).

**Note**

Sys.time may return fractional seconds, but they are ignored by the default conversions (e.g., printing) for class "POSIXct". See the examples and format.POSIXct for ways to reveal them.

**See Also**

date for the system time in a fixed-format character string.

Sys.timezone.

system.time for measuring elapsed/CPU time of expressions.

**Examples**

```r
Sys.time()
## print with possibly greater accuracy:
op <- options(digits.secs = 6)
Sys.time()
options(op)

## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y")
```

```r
Sys.Date()
```
Sys.which

Find Full Paths to Executables

Description

This is an interface to the system command which, or to an emulation on Windows.

Usage

Sys.which(names)

Arguments

names  Character vector of names or paths of possible executables.

Details

The system command which reports on the full path names of an executable (including an executable script) as would be executed by a shell, accepting either absolute paths or looking on the path.

On Windows an ‘executable’ is a file with extension ‘.exe’, ‘.com’, ‘.cmd’ or ‘.bat’. Such files need not actually be executable, but they are what system tries.

On a Unix-alike the full path to which (usually ‘/usr/bin/which’) is found when R is installed.

Value

A character vector of the same length as names, named by names. The elements are either the full path to the executable or some indication that no executable of that name was found. Typically the indication is "", but this does depend on the OS (and the known exceptions are changed to ""). Missing values in names have missing return values.

On Windows the paths will be short paths (8+3 components, no spaces) with \ as the path delimiter.

Note

Except on Windows this calls the system command which: since that is not part of e.g. the POSIX standards, exactly what it does is OS-dependent. It will usually do tilde-expansion and it may make use of csh aliases.

Examples

## the first two are likely to exist everywhere
## texi2dvi exists on most Unix-alikes and under MiKTeX
Sys.which(c("ftp", "ping", "texi2dvi", "this-does-not-exist"))
system **Invoke a System Command**

**Description**

system invokes the OS command specified by command.

**Usage**

```r
system(command, intern = FALSE,
       ignore.stdout = FALSE, ignore.stderr = FALSE,
       wait = TRUE, input = NULL, show.output.on.console = TRUE,
       minimized = FALSE, invisible = TRUE, timeout = 0)
```

**Arguments**

- **command**
  - the system command to be invoked, as a character string.
- **intern**
  - a logical (not NA) which indicates whether to capture the output of the command
    as an R character vector.
- **ignore.stdout, ignore.stderr**
  - a logical (not NA) indicating whether messages written to ‘stdout’ or ‘stderr’
    should be ignored.
- **wait**
  - a logical (not NA) indicating whether the R interpreter should wait for the command
    to finish, or run it asynchronously. This will be ignored (and the interpreter
    will always wait) if intern = TRUE.
- **input**
  - if a character vector is supplied, this is copied one string per line to a temporary
    file, and the standard input of command is redirected to the file.
- **timeout**
  - timeout in seconds, ignored if 0. This is a limit for the elapsed time running
    command in a separate process. Fractions of seconds are ignored.
- **show.output.on.console, minimized, invisible**
  - arguments that are accepted on Windows but ignored on this platform, with a
    warning.

**Details**

This interface has become rather complicated over the years: see `system2` for a more portable and
flexible interface which is recommended for new code.

command is parsed as a command plus arguments separated by spaces. So if the path to the command
(or a single argument such as a file path) contains spaces, it must be quoted e.g. by `shQuote`. Unix-
alikes pass the command line to a shell (normally `/bin/sh`, and POSIX requires that shell), so
command can be anything the shell regards as executable, including shell scripts, and it can contain
multiple commands separated by ;.

On Windows, system does not use a shell and there is a separate function `shell` which passes
command lines to a shell.

If intern is TRUE then `popen` is used to invoke the command and the output collected, line by line,
into an R character vector. If intern is FALSE then the C function `system` is used to invoke the
command.

wait is implemented by appending & to the command: this is in principle shell-dependent, but
required by POSIX and so widely supported.
When timeout is non-zero, the command is terminated after the given number of seconds. The termination works for typical commands, but it is not guaranteed: it is possible to write a program that would keep running after the time is out. Timeouts can only be set with wait = TRUE. The timeout option is currently experimental.

Timeouts cannot be used with interactive commands: the command is run with standard input redirected from /dev/null and it must not modify terminal settings. As long as tty tostop option is disabled, which it usually is by default, the executed command may write to standard output and standard error. One cannot rely on that the execution time of the child processes will be included into user.child and sys.child element of proc.time returned by proc.time. For the time to be included, all child processes have to be waited for by their parents, which has to be implemented in the parent applications.

The ordering of arguments after the first two has changed from time to time: it is recommended to name all arguments after the first.

There are many pitfalls in using system to ascertain if a command can be run — Sys.which is more suitable.

Value

If intern = TRUE, a character vector giving the output of the command, one line per character string. (Output lines of more than 8095 bytes will be split.) If the command could not be run an R error is generated. If command runs but gives a non-zero exit status this will be reported with a warning and in the attribute "status" of the result: an attribute "errmsg" may also be available.

If intern = FALSE, the return value is an error code (0 for success), given the invisible attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is 127 and a warning is issued (as from R 3.5.0). Otherwise if wait = TRUE the value is the exit status returned by the command, and if wait = FALSE it is 0 (the conventional success value).

If the command times out, a warning is reported and the exit status is 124.

Stdout and stderr

For command-line R, error messages written to 'stderr' will be sent to the terminal unless ignore.stderr = TRUE. They can be captured (in the most likely shells) by

```r
system("some command 2>&1", intern = TRUE)
```

For GUIs, what happens to output sent to 'stdout' or 'stderr' if intern = FALSE is interface-specific, and it is unsafe to assume that such messages will appear on a GUI console (they do on the macOS GUI’s console, but not on some others).

Differences between Unix and Windows

How processes are launched differs fundamentally between Windows and Unix-alike operating systems, as do the higher-level OS functions on which this R function is built. So it should not be surprising that there are many differences between OSes in how system behaves. For the benefit of programmers, the more important ones are summarized in this section.

- The most important difference is that on a Unix-alike system launches a shell which then runs command. On Windows the command is run directly – use shell for an interface which runs command via a shell (by default the Windows shell cmd.exe, which has many differences from a POSIX shell).
  This means that it cannot be assumed that redirection or piping will work in system (redirection sometimes does), but we have seen cases where it stopped working after a Windows security patch), and system2 (or shell) must be used on Windows.
What happens to stdout and stderr when not captured depends on how R is running: Windows batch commands behave like a Unix-alike, but from the Windows GUI they are generally lost. system(intern = TRUE) captures ‘stderr’ when run from the Windows GUI console unless ignore.stderr = TRUE.

The behaviour on error is different in subtle ways (and has differed between R versions).

The quoting conventions for command differ, but shQuote is a portable interface.

Arguments show.output.on.console, minimized, invisible only do something on Windows (and are most relevant to Rgui there).

See Also

man system and man sh for how this is implemented on the OS in use.

.Platform for platform-specific variables.

pipe to set up a pipe connection.

Examples

# list all files in the current directory using the -F flag
## Not run: system("ls -F")

# t1 is a character vector, each element giving a line of output from who
# (if the platform has who)
t1 <- try(system("who", intern = TRUE))

try(system("ls fizzlipuzzli", intern = TRUE, ignore.stderr = TRUE))
# zero-length result since file does not exist, and will give warning.

system.file

Find Names of R System Files

Description

Finds the full file names of files in packages etc.

Usage

system.file(..., package = "base", lib.loc = NULL,
  mustWork = FALSE)

Arguments

... character vectors, specifying subdirectory and file(s) within some package. The default, none, returns the root of the package. Wildcards are not supported.

package a character string with the name of a single package. An error occurs if more than one package name is given.

lib.loc a character vector with path names of R libraries. See ‘Details’ for the meaning of the default value of NULL.

mustWork logical. If TRUE, an error is given if there are no matching files.
Details

This checks the existence of the specified files with `file.exists`. So file paths are only returned if there are sufficient permissions to establish their existence.

The unnamed arguments in . . . are usually character strings, but if character vectors they are recycled to the same length.

This uses `find.package` to find the package, and hence with the default `lib.loc = NULL` looks first for attached packages then in each library listed in `.libPaths()`. Note that if a namespace is loaded but the package is not attached, this will look only on `.libPaths()`.

Value

A character vector of positive length, containing the file paths that matched . . ., or the empty string, "", if none matched (unless `mustWork = TRUE`).

If matching the root of a package, there is no trailing separator.

`system.file()` with no arguments gives the root of the `base` package.

See Also

`R.home` for the root directory of the R installation, `list.files`.

`Sys.glob` to find paths via wildcards.

Examples

```r
system.file()  # The root of the 'base' package
system.file(package = "stats")  # The root of package 'stats'
system.file("INDEX")
system.file("help", "AnIndex", package = "splines")
```

---

**system.time**

**CPU Time Used**

Description

Return CPU (and other) times that `expr` used.

Usage

```r
system.time(expr, gcFirst = TRUE)
```

Arguments

- `expr` Valid R expression to be timed.
- `gcFirst` Logical - should a garbage collection be performed immediately before the timing? Default is TRUE.
Details

system.time calls the function proc.time, evaluates expr, and then calls proc.time once more, returning the difference between the two proc.time calls.

unix.time has been an alias of system.time, for compatibility with S, and has finally been deprecated in 2016.

Timings of evaluations of the same expression can vary considerably depending on whether the evaluation triggers a garbage collection. When gcFirst is TRUE a garbage collection (gc) will be performed immediately before the evaluation of expr. This will usually produce more consistent timings.

Value

A object of class "proc_time": see proc.time for details.

See Also

proc.time, time which is for time series.
Sys.time to get the current date & time.

Examples

require(stats)
system.time(for(i in 1:100) mad(runif(1000)))
## Not run:
exT <- function(n = 10000) {
  # Purpose: Test if system.time works ok; n: loop size
  system.time(for(i in 1:n) x <- mean(rt(1000, df = 4)))
}
#-- Try to interrupt one of the following (using Ctrl-C / Escape):
exT()  # about 4 secs on a 2.5GHz Xeon
system.time(exT())  # +/- same
## End(Not run)

system2

Invoke a System Command

Description

system2 invokes the OS command specified by command.

Usage

system2(command, args = character(),
  stdout = "", stderr = "", stdin = "", input = NULL,
  env = character(), wait = TRUE,
  minimized = FALSE, invisible = TRUE, timeout = 0)
Arguments

command  the system command to be invoked, as a character string.
args     a character vector of arguments to command.
stdout, stderr  where output to ‘stdout’ or ‘stderr’ should be sent. Possible values are “”, to
              the R console (the default), NULL or FALSE (discard output), TRUE (capture the
              output in a character vector) or a character string naming a file.
stdin     should input be diverted? “” means the default, alternatively a character string
          naming a file. Ignored if input is supplied.
input     if a character vector is supplied, this is copied one string per line to a temporary
          file, and the standard input of command is redirected to the file.
env       character vector of name=value strings to set environment variables.
wait      a logical (not NA) indicating whether the R interpreter should wait for the com-
          mand to finish, or run it asynchronously. This will be ignored (and the interpreter
          will always wait) if stdout = TRUE.
timeout   timeout in seconds, ignored if 0. This is a limit for the elapsed time running
          command in a separate process. Fractions of seconds are ignored.
minimized, invisible arguments that are accepted on Windows but ignored on this platform, with a
                  warning.

Details

Unlike system, command is always quoted by shQuote, so it must be a single command without
arguments.

For details of how command is found see system.

On Windows, env is only supported for commands such as R and make which accept environment
variables on their command line.

Some Unix commands (such as some implementations of ls) change their output if they consider
it to be piped or redirected: stdout = TRUE uses a pipe whereas stdout = “some_file_name”
uses redirection.

Because of the way it is implemented, on a Unix-alike stderr = TRUE implies stdout = TRUE:
a warning is given if this is not what was specified.

When timeout is non-zero, the command is terminated after the given number of seconds. The
termination works for typical commands, but is not guaranteed: it is possible to write a program
that would keep running after the time is out. Timeouts can only be set with wait = TRUE. The
timeout option is currently experimental.

Timeouts cannot be used with interactive commands: the command is run with standard input
redirected from /dev/null and it must not modify terminal settings. As long as tty tostop option
is disabled, which it usually is by default, the executed command may write to standard output and
standard error.

Value

If stdout = TRUE or stderr = TRUE, a character vector giving the output of the command, one
line per character string. (Output lines of more than 8095 bytes will be split.) If the command could
not be run an R error is generated. If command runs but gives a non-zero exit status this will be
reported with a warning and in the attribute "status" of the result: an attribute "errmsg" may also
be available.
In other cases, the return value is an error code (0 for success), given the invisible attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is 127 and a warning is issued (as from R 3.5.0). Otherwise if wait = TRUE the value is the exit status returned by the command, and if wait = FALSE it is 0 (the conventional success value).

If the command times out, a warning is issued and the exit status is 124.

Note

system2 is a more portable and flexible interface than system. It allows redirection of output without needing to invoke a shell on Windows, a portable way to set environment variables for the execution of command, and finer control over the redirection of stdout and stderr. Conversely, system (and shell on Windows) allows the invocation of arbitrary command lines.

There is no guarantee that if stdout and stderr are both TRUE or the same file that the two streams will be interleaved in order. This depends on both the buffering used by the command and the OS.

system.

---

### t Matrix Transpose

**Description**

Given a matrix or data.frame x, t returns the transpose of x.

**Usage**

```r
t(x)
```

**Arguments**

- `x` a matrix or data frame, typically.

**Details**

This is a generic function for which methods can be written. The description here applies to the default and "data.frame" methods.

A data frame is first coerced to a matrix: see as.matrix. When x is a vector, it is treated as a column, i.e., the result is a 1-row matrix.

**Value**

A matrix, with dim and dimnames constructed appropriately from those of x, and other attributes except names copied across.

**Note**

The conjugate transpose of a complex matrix A, denoted $A^H$ or $A^*$, is computed as Conj(t(A)).
References

Brooks/Cole.

See Also

aperm for permuting the dimensions of arrays.

Examples

```r
a <- matrix(1:30, 5, 6)
ta <- t(a) # i.e., a[i, j] == ta[j, i] for all i, j :
for(j in seq(ncol(a)))
  if(! all(a[, j] == ta[j, ])) stop("wrong transpose")
```

**Description**

table uses the cross-classifying factors to build a contingency table of the counts at each combination of factor levels.

**Usage**

table(...,
       exclude = if (useNA == "no") c(NA, NaN),
       useNA = c("no", "ifany", "always"),
       dnn = list.names(...), deparse.level = 1)

as.table(x, ...)
is.table(x)

## S3 method for class 'table'
as.data.frame(x, row.names = NULL, ...,
              responseName = "Freq", stringsAsFactors = TRUE,
              sep = "", base = list(LETTERS))

**Arguments**

... one or more objects which can be interpreted as factors (including character
strings), or a list (or data frame) whose components can be so interpreted. (For
as.table, arguments passed to specific methods; for as.data.frame, unused.)

exclude levels to remove for all factors in .... If it does not contain NA and useNA is not
specifed, it implies useNA = "ifany". See 'Details' for its interpretation for
non-factor arguments.

useNA whether to include NA values in the table. See 'Details'. Can be abbreviated.

dnn the names to be given to the dimensions in the result (the dimnames names).
deparse.level controls how the default dnn is constructed. See 'Details'.
x an arbitrary \( \mathbb{R} \) object, or an object inheriting from class "table" for the as.data.frame method. Note that as.data.frame.table(x, *) may be called explicitly for non-table x for “reshaping” arrays.

row.names a character vector giving the row names for the data frame.

responseName The name to be used for the column of table entries, usually counts.

stringsAsFactors logical: should the classifying factors be returned as factors (the default) or character vectors?

sep, base passed to provideDimnames.

Details

If the argument dnn is not supplied, the internal function list.names is called to compute the ‘dimname names’. If the arguments in \( \ldots \) are named, those names are used. For the remaining arguments, deparse.level = 0 gives an empty name, deparse.level = 1 uses the supplied argument if it is a symbol, and deparse.level = 2 will deparse the argument.

Only when exclude is specified (i.e., not by default) and non-empty, will table potentially drop levels of factor arguments.

useNA controls if the table includes counts of NA values: the allowed values correspond to never ("no"), only if the count is positive ("ifany") and even for zero counts ("always"). Note the somewhat “pathological” case of two different kinds of NAs which are treated differently, depending on both useNA and exclude, see d.patho in the ‘Examples’ below.

Both exclude and useNA operate on an “all or none” basis. If you want to control the dimensions of a multiway table separately, modify each argument using factor or addNA.

Non-factor arguments a are coerced factor(a, exclude=exclude). Since R 3.4.0, care is taken not to count the excluded values (where they were included in the NA count, previously).

The summary method for class "table" (used for objects created by table or xtabs) which gives basic information and performs a chi-squared test for independence of factors (note that the function chisq.test currently only handles 2-d tables).

Value

table() returns a contingency table, an object of class "table", an array of integer values. Note that unlike S the result is always an array, a 1D array if one factor is given.

as.table and is.table coerce to and test for contingency table, respectively.

The as.data.frame method for objects inheriting from class "table" can be used to convert the array-based representation of a contingency table to a data frame containing the classifying factors and the corresponding entries (the latter as component named by responseName). This is the inverse of xtabs.

References

See Also

tabulate is the underlying function and allows finer control.

Use ftable for printing (and more) of multidimensional tables. margin.table, prop.table, addmargins.
addNA for constructing factors with NA as a level.
xtabs for cross tabulation of data frames with a formula interface.

Examples

```
require(stats) # for rpois and xtabs
## Simple frequency distribution
table(rpois(100, 5))
## Check the design:
with(warpbreaks, table(wool, tension))
table(state.division, state.region)

# simple two-way contingency table
with(airquality, table(cut(Temp, quantile(Temp)), Month))
```

```
a <- letters[1:3]
table(a, sample(a))
  # dnn is c("a","")
table(a, sample(a), deparse.level = 0)
  # dnn is c("","")
table(a, sample(a), deparse.level = 2)
  # dnn is c("a","sample(a)")
```

```
## xtabs() <-> as.data.frame.table():
UCBAdmissions # already a contingency table
DF <- as.data.frame(UCBAdmissions)
class(tab <- xtabs(Freq ~ ., DF)) # xtabs & table
## tab *is* "the same" as the original table:
all(tab == UCBAdmissions)
all.equal(dimnames(tab), dimnames(UCBAdmissions))
a <- rep(c(NA, 1/0:3), 10)
table(a)
  # does not report NA's
b <- factor(rep(c("A","B","C"), 10))
table(b)
a <- rep(c(NA, 1/0:3), 10)
table(a, exclude = NULL)
  # reports NA's

```

```
## NA counting:
is.na(d) <- 3:4
d.<- addNA(d)
d.[1:7]
table(d.) # ", exclude = NULL" is not needed
## i.e., if you want to count the NA's of 'd', use
table(d, useNA = "ifany")
```

```
## "pathological" case:
d.patho <- addNA(c(1,NA,1:2,1:3))[-7]; is.na(d.patho) <- 3:4
d.patho
## just 3 consecutive NA's? --- well, have *two* kinds of NAs here:
  as.integer(d.patho) # 1 4 NA NA 1 2
##
## In R >= 3.4.0, table() allows to differentiate:
table(d.patho)
  # counts the "usual" NA
table(d.patho, useNA = "ifany")
  # counts all three
table(d.patho, exclude = NULL)
  # (ditto)
table(d.patho, exclude = NA) # counts none
```
## Two-way tables with NA counts. The 3rd variant is absurd, but shows something that cannot be done using exclude or useNA.

```r
with(airquality,
    table(OzHi = Ozone > 80, Month, useNA = "ifany"))
with(airquality,
    table(OzHi = Ozone > 80, Month, useNA = "always"))
with(airquality,
    table(OzHi = Ozone > 80, addNA(Month)))
```

### Tabulation for Vectors

**Description**

`tabulate` takes the integer-valued vector `bin` and counts the number of times each integer occurs in it.

**Usage**

```r
tabulate(bin, nbins = max(1, bin, na.rm = TRUE))
```

**Arguments**

- `bin`: a numeric vector (of positive integers), or a factor. Long vectors are supported.
- `nbins`: the number of bins to be used.

**Details**

`tabulate` is the workhorse for the `table` function.

If `bin` is a factor, its internal integer representation is tabulated.

If the elements of `bin` are numeric but not integers, they are truncated by `as.integer`.

**Value**

An integer valued `integer` or `double` vector (without names). There is a bin for each of the values 1, ..., `nbins`; values outside that range and NAs are (silently) ignored.

On 64-bit platforms `bin` can have $2^{31}$ or more elements (i.e., `length(bin) > .Machine$integer.max`), and hence a count could exceed the maximum integer. For this reason, the return value is of type double for such long `bin` vectors.

**See Also**

`table`, `factor`.

**Examples**

```r
tabulate(c(2,3,5))
tabulate(c(2,3,3,5), nbins = 10)
tabulate(c(-2,0,2,3,5)) # -2 and 0 are ignored
tabulate(c(-2,0,2,3,5), nbins = 3)
tabulate(factor(letters[1:10]))
```
Apply a Function Over a Ragged Array

Description

Apply a function to each cell of a ragged array, that is to each (non-empty) group of values given by a unique combination of the levels of certain factors.

Usage

tapply(X, INDEX, FUN = NULL, ..., default = NA, simplify = TRUE)

Arguments

- **X**: an R object for which a `split` method exists. Typically vector-like, allowing subsetting with `[`.
- **INDEX**: a list of one or more factors, each of same length as X. The elements are coerced to factors by `as.factor`.
- **FUN**: the function to be applied, or NULL. In the case of functions like `+`, `%*%`, etc., the function name must be backquoted or quoted. If FUN is NULL, tapply returns a vector which can be used to subscript the multi-way array tapply normally produces.
- **...**: optional arguments to FUN; the Note section.
- **default** (only in the case of simplification to an array) the value with which the array is initialized as `array(default, dim = ...)`. Before R 3.4.0, this was hard coded to `array()`’s default NA. If it is NA (the default), the missing value of the answer type, e.g. `NA_real_`, is chosen (as.raw(0) for "raw"). In a numerical case, it may be set, e.g., to `FUN(integer(0))`, e.g., in the case of `FUN = sum` to 0 or `0L`.
- **simplify** logical; if FALSE, tapply always returns an array of mode "list"; in other words, a list with a `dim` attribute. If TRUE (the default), then if FUN always returns a scalar, tapply returns an array with the mode of the scalar.

Value

If FUN is not NULL, it is passed to `match.fun`, and hence it can be a function or a symbol or character string naming a function.

When FUN is present, tapply calls FUN for each cell that has any data in it. If FUN returns a single atomic value for each such cell (e.g., functions `mean` or `var`) and when simplify is TRUE, tapply returns a multi-way array containing the values, and NA for the empty cells. The array has the same number of dimensions as INDEX has components; the number of levels in a dimension is the number of levels (`nlevels()`) in the corresponding component of INDEX. Note that if the return value has a class (e.g., an object of class "Date") the class is discarded.

Note that contrary to S, `simplify = TRUE` always returns an array, possibly 1-dimensional.

If FUN does not return a single atomic value, tapply returns an array of mode `list` whose components are the values of the individual calls to FUN, i.e., the result is a list with a `dim` attribute.

When there is an array answer, its `dimnames` are named by the names of INDEX and are based on the levels of the grouping factors (possibly after coercion).

For a list result, the elements corresponding to empty cells are NULL.
Note

Optional arguments to \texttt{FUN} supplied by the \ldots argument are not divided into cells. It is therefore inappropriate for \texttt{FUN} to expect additional arguments with the same length as \texttt{X}.

Examples

\begin{verbatim}
require(stats)

groups <- as.factor(rbinom(32, n = 5, prob = 0.4))
tapply(groups, groups, length) #-> is almost the same as table(groups)

## contingency table from data.frame : array with named dimnames
tapply(warpbreaks$breaks, warpbreaks[, -1], sum)
tapply(warpbreaks$breaks, warpbreaks[, 3, drop = FALSE], sum)

n <- 17; fac <- factor(rep_len(1:3, n), levels = 1:5)
table(fac)
tapply(1:n, fac, sum)
tapply(1:n, fac, sum, default = 0) # maybe more desirable
tapply(1:n, fac, sum, simplify = FALSE)
tapply(1:n, fac, range)
tapply(1:n, fac, quantile)
tapply(1:n, fac, length) # NA's
tapply(1:n, fac, length, default = 0) # == table(fac)

## example of ... argument: find quarterly means

ind <- list(c(1, 2, 2), c("A", "A", "B"))
table(ind)
tapply(1:3, ind) #-> the split vector

## Some assertions (not held by all patch propsals):
	nq <- names(quantile(1:5))

stopifnot(
  identical(tapply(1:3, ind), c(1L, 2L, 4L)),
  identical(tapply(1:3, ind, sum),
    matrix(c(1L, 2L, NA, 3L), 2, dimnames = list(c("1", "2"), c("A", "B")))),
  identical(tapply(1:n, fac, quantile)[-1],
    array(list("2" = structure(c(2, 5.75, 9.5, 13.25, 17), .Names = nq),
      "3" = structure(c(3, 6, 9, 12, 15), .Names = nq),
      "4" = NULL, "5" = NULL), dim=4, dimnames=list(as.character(2:5))))
\end{verbatim}
taskCallback

Add or Remove a Top-Level Task Callback

Description

addTaskCallback registers an R function that is to be called each time a top-level task is completed. removeTaskCallback un-registers a function that was registered earlier via addTaskCallback. These provide low-level access to the internal/native mechanism for managing task-completion actions. One can use taskCallbackManager at the S-language level to manage S functions that are called at the completion of each task. This is easier and more direct.

Usage

addTaskCallback(f, data = NULL, name = character())
removeTaskCallback(id)

Arguments

f
the function that is to be invoked each time a top-level task is successfully completed. This is called with 5 or 4 arguments depending on whether data is specified or not, respectively. The return value should be a logical value indicating whether to keep the callback in the list of active callbacks or discard it.
data
if specified, this is the 5-th argument in the call to the callback function f.
id
a string or an integer identifying the element in the internal callback list to be removed. Integer indices are 1-based, i.e. the first element is 1. The names of currently registered handlers is available using getTaskCallbackNames and is also returned in a call to addTaskCallback.
name
character: names to be used.

Details

Top-level tasks are individual expressions rather than entire lines of input. Thus an input line of the form expression1 ; expression2 will give rise to 2 top-level tasks.

A top-level task callback is called with the expression for the top-level task, the result of the top-level task, a logical value indicating whether it was successfully completed or not (always TRUE at present), and a logical value indicating whether the result was printed or not. If the data argument was specified in the call to addTaskCallback, that value is given as the fifth argument.

The callback function should return a logical value. If the value is FALSE, the callback is removed from the task list and will not be called again by this mechanism. If the function returns TRUE, it is kept in the list and will be called on the completion of the next top-level task.

Value

addTaskCallback returns an integer value giving the position in the list of task callbacks that this new callback occupies. This is only the current position of the callback. It can be used to remove the entry as long as no other values are removed from earlier positions in the list first.
removeTaskCallback returns a logical value indicating whether the specified element was removed. This can fail (i.e., return FALSE) if an incorrect name or index is given that does not correspond to the name or position of an element in the list.
Note

There is also C-level access to top-level task callbacks to allow C routines rather than R functions be used.

getcallbackNames  taskCallbackManager  https://developer.r-project.org/TaskHandlers.pdf

Examples

times <- function(total = 3, str = "Task a") {
  ctr <- 0
  function(expr, value, ok, visible) {
    ctr <<- ctr + 1
    cat(str, ctr, "\n")
    keep.me <- (ctr < total)
    if (!keep.me)
      cat("handler removing itself\n")

    # return
    keep.me
  }
}

# add the callback that will work for
# 4 top-level tasks and then remove itself.
n <- addTaskCallback(times(4))

# now remove it, assuming it is still first in the list.
removeTaskCallback(n)

## See how the handler is called every time till "self destruction":

addTaskCallback(times(4)) # counts as once already

sum(1:10); mean(1:3) # two more
sinpi(1) # 4th and "done"
cospi(1)
tanpi(1)
taskCallbackManager

Usage

taskCallbackManager(handlers = list(), registered = FALSE, verbose = FALSE)

Arguments

handlers  this can be a list of callbacks in which each element is a list with an element named "f" which is a callback function, and an optional element named "data" which is the 5-th argument to be supplied to the callback when it is invoked. Typically this argument is not specified, and one uses add to register callbacks after the manager is created.

registered  a logical value indicating whether the evaluate function has already been registered with the internal task callback mechanism. This is usually FALSE and the first time a callback is added via the add function, the evaluate function is automatically registered. One can control when the function is registered by specifying TRUE for this argument and calling addTaskCallback manually.

verbose  a logical value, which if TRUE, causes information to be printed to the console about certain activities this dispatch manager performs. This is useful for debugging callbacks and the handler itself.

Value

A list containing 6 functions:

add  register a callback with this manager, giving the function, an optional 5-th argument, an optional name by which the callback is stored in the list, and a register argument which controls whether the evaluate function is registered with the internal C-level dispatch mechanism if necessary.

remove  remove an element from the manager’s collection of callbacks, either by name or position/index.

evaluate  the ‘real’ callback function that is registered with the C-level dispatch mechanism and which invokes each of the R-level callbacks within this manager’s control.

suspend  a function to set the suspend state of the manager. If it is suspended, none of the callbacks will be invoked when a task is completed. One sets the state by specifying a logical value for the status argument.

register  a function to register the evaluate function with the internal C-level dispatch mechanism. This is done automatically by the add function, but can be called manually.

callbacks  returns the list of callbacks being maintained by this manager.

Examples

# create the manager
h <- taskCallbackManager()
# add a callback

```r
cat("In handler\n")
return(TRUE)
```

add(function(expr, value, ok, visible)

# look at the internal callbacks.

getTaskCallbackNames()

# look at the R-level callbacks

names(h$callbacks())

getTaskCallbackNames()

removeTaskCallback("R-taskCallbackManager")

---

**taskCallbackNames**

*Query the Names of the Current Internal Top-Level Task Callbacks*

**Description**

This provides a way to get the names (or identifiers) for the currently registered task callbacks that are invoked at the conclusion of each top-level task. These identifiers can be used to remove a callback.

**Usage**

getTaskCallbackNames()

**Value**

A character vector giving the name for each of the registered callbacks which are invoked when a top-level task is completed successfully. Each name is the one used when registering the callbacks and returned as the in the call to `addTaskCallback`.

**Note**

One can use `taskCallbackManager` to manage user-level task callbacks, i.e., S-language functions, entirely within the S language and access the names more directly.

**See Also**

`addTaskCallback`, `removeTaskCallback`, `taskCallbackManager`

https://developer.r-project.org/TaskHandlers.pdf

**Examples**

```r
n <- addTaskCallback(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")

getTaskCallbackNames()

  # now remove it by name
```
removeTaskCallback("simpleHandler")

h <- taskCallbackManager()
h$add(function(expr, value, ok, visible) {
cat("In handler\n")
return(TRUE)
}, name = "simpleHandler")
getTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")

tempfile

Create Names for Temporary Files

Description

tempfile returns a vector of character strings which can be used as names for temporary files.

Usage

tempfile(pattern = "file", tmpdir = tempdir(), fileext = ")
tempdir(check = FALSE)

Arguments

pattern a non-empty character vector giving the initial part of the name.
tmpdir a non-empty character vector giving the directory name
fileext a non-empty character vector giving the file extension
check logical indicating if tmpdir() should be checked and recreated if no longer valid.

Details

The length of the result is the maximum of the lengths of the three arguments; values of shorter arguments are recycled.

The names are very likely to be unique among calls to tempfile in an R session and across simultaneous R sessions (unless tmpdir is specified). The filenames are guaranteed not to be currently in use.

The file name is made by concatenating the path given by tmpdir, the pattern string, a random string in hex and a suffix of fileext.

By default, tmpdir will be the directory given by tempdir(). This will be a subdirectory of the per-session temporary directory found by the following rule when the R session is started. The environment variables TMPDIR, TMP and TEMP are checked in turn and the first found which points to a writable directory is used: if none succeeds ‘/tmp’ is used. The path should not contain spaces. Note that setting any of these environment variables in the R session has no effect on tempdir(): the per-session temporary directory is created before the interpreter is started.
Value

For `tempfile` a character vector giving the names of possible (temporary) files. Note that no files are generated by `tempfile`.

For `tempdir`, the path of the per-session temporary directory. The value will be an absolute path (unless `tmpdir` is set to a relative path), but it need not be canonical (see `normalizePath`) and on macOS usually is not.

Note on parallel

R processes forked by functions such as `mclapply` and `makeForkCluster` in package `parallel` share a per-session temporary directory. Further, the 'guaranteed not to be currently in use' applies only at the time of asking, and two children could ask simultaneously. This is circumvented by ensuring that `tempfile` calls in different children try different names.

Source

The final component of `tempdir()` is created by the POSIX system call `mkdtmp`, or if this is not available (e.g. on Windows) a version derived from the source code of GNU glibc.

It will be of the form `RtmpXXXXXX` where the last 6 characters are replaced in a platform-specific way. POSIX only requires that the replacements be ASCII, which allows . (so the value may appear to have a file extension) and regexp metacharacters such as ., Most commonly the replacements are from the `regexp` pattern `[A-Za-z0-9]`, but . has been seen.

References

See Also

`unlink` for deleting files.

Examples

tempfile(c("ab", "a b c"))  # give file name with spaces in!
tempfile("plot", fileext = c(".ps", ".pdf"))
tempdir()  # works on all platforms with a platform-dependent result

## Show how 'check' is working on some platforms:
if(exists("I'm brave") && 'I'm brave' && identical(.Platform$OS.type, "unix") && grepl("/tmp/", tempdir())) {
cat("Current tempdir(): ", tempdir(), "\n")
cat("Removing it : ", file.remove(tempdir()), ", dir.exists(tempdir()): ", dir.exists(tempdir()), "\n")
cat("and now tempdir(check = TRUE): ", tempdir(check = TRUE),"\n")
}
Description

Input and output text connections.

Usage

textConnection(object, open = "r", local = FALSE,
               encoding = c("", "bytes", "UTF-8"))

textConnectionValue(con)

Arguments

object character. A description of the connection. For an input this is an R character vector object, and for an output connection the name for the R character vector to receive the output, or NULL (for none).
open character string. Either "r" (or equivalently ") for an input connection or "w" or "a" for an output connection.
local logical. Used only for output connections. If TRUE, output is assigned to a variable in the calling environment. Otherwise the global environment is used.
encoding character string, partially matched. Used only for input connections. How marked strings in object should be handled: converted to the current locale, used byte-by-byte or translated to UTF-8.
con An output text connection.

Details

An input text connection is opened and the character vector is copied at time the connection object is created, and close destroys the copy. object should be the name of a character vector: however, short expressions will be accepted provided they deparse to less than 60 bytes.

An output text connection is opened and creates an R character vector of the given name in the user’s workspace or in the calling environment, depending on the value of the local argument. This object will at all times hold the completed lines of output to the connection, and isIncomplete will indicate if there is an incomplete final line. Closing the connection will output the final line, complete or not. (A line is complete once it has been terminated by end-of-line, represented by "\n" in R.) The output character vector has locked bindings (see lockBinding) until close is called on the connection. The character vector can also be retrieved via textConnectionValue, which is the only way to do so if object = NULL. If the current locale is detected as Latin-1 or UTF-8, non-ASCII elements of the character vector will be marked accordingly (see Encoding).

Opening a text connection with mode = "a" will attempt to append to an existing character vector with the given name in the user’s workspace or the calling environment. If none is found (even if an object exists of the right name but the wrong type) a new character vector will be created, with a warning.

You cannot seek on a text connection, and seek will always return zero as the position.

Text connections have slightly unusual semantics: they are always open, and throwing away an input text connection without closing it (so it get garbage-collected) does not give a warning.
For `textConnection`, a connection object of class "textConnection" which inherits from class "connection".
For `textConnectionValue`, a character vector.

Note
As output text connections keep the character vector up to date line-by-line, they are relatively expensive to use, and it is often better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

close(zz)
cat(foo, sep = "\n")
```
tilde

Tilde Operator

Description

Tilde is used to separate the left- and right-hand sides in a model formula.

Usage

y ~ model

Arguments

y, model symbolic expressions.

Details

The left-hand side is optional, and one-sided formulae are used in some contexts.

A formula has mode call. It can be subsetted by [[: the components are ~, the left-hand side (if present) and the right-hand side in that order.

timezones

Time Zones

Description

Information about time zones in R. Sys.timezone returns the name of the current time zone.

Usage

Sys.timezone(location = TRUE)

OlsonNames()

Arguments

location logical: should an attempt be made to find the location name as used in the Olson/IANA database? (See ‘Time zone names’ below.)
Details

Time zones are a system-specific topic, but these days almost all R platforms use similar underlying code, used by Linux, macOS, Solaris, AIX, FreeBSD, Sun Java >= 1.4 and Tcl >= 8.5, and installed with R on Windows. Unfortunately there are many system-specific errors in the implementations. It is possible to use R’s own version of the code on Unix-alikes as well as on Windows: this is the default for macOS and recommended for Solaris.

It should be possible to set the time zone via the environment variable TZ: see the section on ‘Time zone names’ for suitable values. Sys.timezone() will return the value of TZ if set (and on some OSes it is always set), otherwise it will try to retrieve a value which if set for TZ would give the current time zone. This is not in general possible, and then Sys.timezone(FALSE) will retrieve the abbreviation used for the current time.

If TZ is set but empty or invalid, most platforms default to ‘UTC’, the time zone colloquially known as ‘GMT’ (see https://en.wikipedia.org/wiki/Coordinated_Universal_Time). (Some but not all platforms will give a warning for invalid time zones.)

Time zones did not come into use until the second half of the nineteenth century and were not widely adopted until the twentieth, and daylight saving time (DST, also known as summer time) was first introduced in the early twentieth century, most widely in 1916. Over the last 100 years places have changed their affiliation between major time zones, have opted out of (or in to) DST in various years or adopted DST rule changes late or not at all.

A quite common system implementation of POSIXct is as signed 32-bit integers and so only goes back to the end of 1901: on such systems R assumes that dates prior to that are in the same time zone as they were in 1902. Most of the world had not adopted time zones by 1902 (so used local ‘mean time’ based on longitude) but for a few places there had been time-zone changes before then. 64-bit representations are becoming common; unfortunately on some 64-bit OSes (notably macOS) the database information is 32-bit and so only available for the range 1901–2038, and incompletely for the end years.

Value

Sys.timezone returns an OS-specific character string, possibly NA or an empty string (which on some OSes means ‘UTC’). For the default location = TRUE this will be a location such as "Europe/London" if one can be ascertained. For location = FALSE this may be an abbreviation such as "EST" or "CEST".

OlsonNames returns a character vector, see the examples for typical cases.

Time zone names

Names "UTC" and its synonym "GMT" are accepted on all platforms.

Where OSes describe their valid time zones can be obscure. The help for the C function tzset can be helpful, but it can also be inaccurate. There is a cumbersome POSIX specification (listed under environment variable TZ at http://pubs.opengroup.org/onlinepubs/9699919799/basedefs/V1_chap08.html#tag_08), which is often at least partially supported, but there are other more user-friendly ways to specify time zones.

Almost all R platforms make use of a time-zone database originally compiled by Arthur David Olson and now managed by IANA, in which the preferred way to refer to a time zone is by a location (typically of a city), e.g., Europe/London, America/Los_Angeles, Pacific/Easter. Some traditional designations are also allowed such as EST5EDT or GB. (Beware that some of these designations may not be what you expect: in particular EST is a time zone used in Canada without daylight saving time, and not EST5EDT nor (Australian) Eastern Standard Time.) The designation can also be an optional colon prepended to the path to a file giving complied zone information (and the examples
above are all files in a system-specific location). See http://www.twinsun.com/tz/tz-link.htm for more details and references. By convention, regions with a unique time-zone history since 1970 have specific names in the database, but those with different earlier histories may not. Each time zone has one or two (the second for DST) **abbreviations** used when formatting times.

The abbreviations used have changed over the years: for example France used ‘PMT’ (‘Paris Mean Time’) from 1891 to 1911 then ‘WET/WEST’ up to 1940 and ‘CET/CEST’ from 1946. (In almost all time zones the abbreviations have been stable since 1970.) The POSIX standard allows only one or two abbreviations per time zone, so you may see the current abbreviation(s) used for older times.

The function `OlsonNames` returns the time-zone names known to the Olson/IANA database on the current system. The system-specific location in the file system varies, e.g. ‘/usr/share/zoneinfo’ (Linux, macOS, FreeBSD), ‘/usr/share/lib/zoneinfo’ (Solaris, AIX), … It is likely that there is a file named something like ‘zone.tab’ under that directory listing the locations known as time-zone names (but not for example EST5EDT): this is read by OlsonNames. See also https://en.wikipedia.org/wiki/Zone.tab.

Where `R` was configured with option ‘--with-internal-tzcode’ (the default on macOS and Windows: recommended on Solaris), the database at `file.path(R.home("share"), "zoneinfo")` is used by default: file ‘VERSION’ in that directory states the version. Environment variable `TZDIR` can be used to point to a different ‘zoneinfo’ directory: this is also supported by the native services on some OSes, e.g. Linux).

Most platforms support time zones of the form ‘GMT+n’ and ‘GMT-n’, which assume at a fixed offset from UTC (hence no DST). Contrary to some expectations (but consistent with names such as ‘PST8PDT’), negative offsets are times ahead of (east of) UTC, positive offsets are times behind (west of) UTC.

Immediately prior to the advent of legislated time zones, most people used time based on their longitude (or that of a nearby town), known as ‘Local Mean Time’ and abbreviated as ‘LMT’ in the databases: in many countries that was codified with a specific name before the switch to a standard time. For example, Paris codified its LMT as ‘Paris Mean Time’ in 1891 (to be used throughout mainland France) and switched to ‘GMT+0’ in 1911.

Some systems (notably Linux) have a `tzselect` command which allows the interactive selection of a supported time zone name.

**Warning**

There is a system-specific upper limit on the number of bytes in (abbreviated) time-zone names which can be as low as 6 (as required by POSIX). Some OSes allow the setting of time zones with names which exceed their limit, and that can crash the `R` session.

`OlsonNames` tries to find an Olson database in known locations. It might not succeed (when it returns an empty vector with a warning) and even if it does it might not locate the database used by the date-time code linked into `R`. Fortunately names are added rarely and most databases are pretty complete.

**Note**

Since 2007 there has been considerable disruption over changes to the timings of the DST transitions, aimed at energy conservation. These often have short notice and time-zone databases may not be up to date. (Morocco in 2013 announced a change to the end of DST at a days notice, and in 2015 North Korea gave imprecise information about a change a week in advance.)

On platforms with case-insensitive file systems, time zone names will be case-insensitive. They may or may not be on other platforms and so, for example, "gmt" is valid on some platforms and not on others.
Note that except where replaced, the operation of time zones is an OS service, and even where replaced a third-party database is used and can be updated (see the section on 'Time zone names'). Incorrect results will never be an R issue, so please ensure that you have the courtesy not to blame R for them.

toString

Convert an R Object to a Character String

Description

This is a helper function for format to produce a single character string describing an R object.

Usage

toString(x, ...)

## Default S3 method:
toString(x, width = NULL, ...)

Arguments

x

The object to be converted.

width

Suggestion for the maximum field width. Values of NULL or 0 indicate no maximum. The minimum value accepted is 6 and smaller values are taken as 6.

... Optional arguments passed to or from methods.
Details

This is a generic function for which methods can be written: only the default method is described here. Most methods should honor the width argument to specify the maximum display width (as measured by \texttt{nchar(type = "width")} of the result.

The default method first converts \( x \) to character and then concatenates the elements separated by ",". If \( width \) is supplied and is not \texttt{NULL}, the default method returns the first \( width - 4 \) characters of the result with \ldots{} appended, if the full result would use more than \( width \) characters.

Value

A character vector of length 1 is returned.

trace Interactive Tracing and Debugging of Calls to a Function or Method

Description

A call to \texttt{trace} allows you to insert debugging code (e.g., a call to \texttt{browser} or \texttt{recover}) at chosen places in any function. A call to \texttt{untrace} cancels the tracing. Specified methods can be traced the same way, without tracing all calls to the generic function. Trace code (\texttt{tracer}) can be any \texttt{R} expression. Tracing can be temporarily turned on or off globally by calling \texttt{tracingState}.

Usage

\begin{verbatim}
trace(what, tracer, exit, at, print, signature,
     where = topenv(parent.frame()), edit = FALSE)
untrace(what, signature = NULL, where = topenv(parent.frame()))
	
.tracingState(on = NULL)
   .doTrace(expr, msg)
   returnValue(default = NULL)
\end{verbatim}
Arguments

what: The name (quoted or not) of a function to be traced or untraced. For untrace or for trace with more than one argument, more than one name can be given in the quoted form, and the same action will be applied to each one.

tracer: either a function or an unevaluated expression. The function will be called or the expression will be evaluated either at the beginning of the call, or before those steps in the call specified by the argument at. See the details section.

exit: either a function or an unevaluated expression. The function will be called or the expression will be evaluated on exiting the function. See the details section.

at: optional numeric vector or list. If supplied, tracer will be called just before the corresponding step in the body of the function. See the details section.

print: If TRUE (as per default), a descriptive line is printed before any trace expression is evaluated.

signature: If this argument is supplied, it should be a signature for a method for function what. In this case, the method, and not the function itself, is traced.

edit: For complicated tracing, such as tracing within a loop inside the function, you will need to insert the desired calls by editing the body of the function. If so, supply the edit argument either as TRUE, or as the name of the editor you want to use. Then trace() will call edit and use the version of the function after you edit it. See the details section for additional information.

where: where to look for the function to be traced; by default, the top-level environment of the call to trace.

An important use of this argument is to trace a function when it is called from a package with a namespace. The current namespace mechanism imports the functions to be called (with the exception of functions in the base package). The functions being called are not the same objects seen from the top-level (in general, the imported packages may not even be attached). Therefore, you must ensure that the correct versions are being traced. The way to do this is to set argument where to a function in the namespace. The tracing computations will then start looking in the environment of that function (which will be the namespace of the corresponding package). (Yes, it’s subtle, but the semantics here are central to how namespaces work in R.)

on: logical; a call to the support function tracingState returns TRUE if tracing is globally turned on, FALSE otherwise. An argument of one or the other of those values sets the state. If the tracing state is FALSE, none of the trace actions will actually occur (used, for example, by debugging functions to shut off tracing during debugging).

expr, msg: arguments to the support function .doTrace, calls to which are inserted into the modified function or method: expr is the tracing action (such as a call to browser()), and msg is a string identifying the place where the trace action occurs.

default: If returnValue finds no return value (e.g. a function exited because of an error, restart or as a result of evaluating a return from a caller function), it will return default instead.

Details

The trace function operates by constructing a revised version of the function (or of the method, if signature is supplied), and assigning the new object back where the original was found. If only
the what argument is given, a line of trace printing is produced for each call to the function (back compatible with the earlier version of trace).

The object constructed by trace is from a class that extends “function” and which contains the original, untraced version. A call to untrace re-assigns this version.

If the argument tracer or exit is the name of a function, the tracing expression will be a call to that function, with no arguments. This is the easiest and most common case, with the functions browser and recover the likeliest candidates; the former browses in the frame of the function being traced, and the latter allows browsing in any of the currently active calls.

The tracer or exit argument can also be an unevaluated expression (such as returned by a call to quote or substitute). This expression itself is inserted in the traced function, so it will typically involve arguments or local objects in the traced function. An expression of this form is useful if you only want to interact when certain conditions apply (and in this case you probably want to supply print = FALSE in the call to trace also).

When the at argument is supplied, it can be a vector of integers referring to the substeps of the body of the function (this only works if the body of the function is enclosed in { ...}). In this case tracer is not called on entry, but instead just before evaluating each of the steps listed in at. (Hint: you don’t want to try to count the steps in the printed version of a function; instead, look at as.list(body(f)) to get the numbers associated with the steps in function f.)

The at argument can also be a list of integer vectors. In this case, each vector refers to a step nested within another step of the function. For example, at = list(c(3,4)) will call the tracer just before the fourth step of the third step of the function. See the example below.

Using setBreakpoint (from package utils) may be an alternative, calling trace(...., at, ...).

The exit argument is called during on.exit processing. In an on.exit expression, the experimental returnValue() function may be called to obtain the value about to be returned by the function. Calling this function in other circumstances will give undefined results.

An intrinsic limitation in the exit argument is that it won’t work if the function itself uses on.exit with add= FALSE (the default), since the existing calls will override the one supplied by trace.

Tracing does not nest. Any call to trace replaces previously traced versions of that function or method (except for edited versions as discussed below), and untrace always restores an untraced version. (Allowing nested tracing has too many potentials for confusion and for accidentally leaving traced versions behind.)

When the edit argument is used repeatedly with no call to untrace on the same function or method in between, the previously edited version is retained. If you want to throw away all the previous tracing and then edit, call untrace before the next call to trace. Editing may be combined with automatic tracing; just supply the other arguments such as tracer, and the edit argument as well. The edit = TRUE argument uses the default editor (see edit).

Tracing primitive functions (builtins and specials) from the base package works, but only by a special mechanism and not very informatively. Tracing a primitive causes the primitive to be replaced by a function with argument ...(only). You can get a bit of information out, but not much. A warning message is issued when trace is used on a primitive.

The practice of saving the traced version of the function back where the function came from means that tracing carries over from one session to another, if the traced function is saved in the session image. (In the next session, untrace will remove the tracing.) On the other hand, functions that were in a package, not in the global environment, are not saved in the image, so tracing expires with the session for such functions.

Tracing a method is basically just like tracing a function, with the exception that the traced version is stored by a call to setMethod rather than by direct assignment, and so is the untraced version after a call to untrace.
The version of `trace` described here is largely compatible with the version in S-Plus, although the two work by entirely different mechanisms. The S-Plus `trace` uses the session frame, with the result that tracing never carries over from one session to another (R does not have a session frame). Another relevant distinction has nothing directly to do with `trace`: The browser in S-Plus allows changes to be made to the frame being browsed, and the changes will persist after exiting the browser. The R browser allows changes, but they disappear when the browser exits. This may be relevant in that the S-Plus version allows you to experiment with code changes interactively, but the R version does not. (A future revision may include a ‘destructive’ browser for R.)

**Value**

In the simple version (just the first argument), `trace` returns an invisible `NULL`. Otherwise, the traced function(s) name(s). The relevant consequence is the assignment that takes place.

`untrace` returns the function name invisibly.

`tracingState` returns the current global tracing state, and possibly changes it.

When called during on.exit processing, `returnValue` returns the value about to be returned by the exiting function. Behaviour in other circumstances is undefined.

**Note**

Using `trace()` is conceptually a generalization of `debug`, implemented differently. Namely by calling `browser` via its tracer or exit argument.

The version of function tracing that includes any of the arguments except for the function name requires the `methods` package (because it uses special classes of objects to store and restore versions of the traced functions).

If methods dispatch is not currently on, `trace` will load the methods namespace, but will not put the methods package on the `search` list.

**See Also**

`browser` and `recover`, the likeliest tracing functions; also, `quote` and `substitute` for constructing general expressions.

**Examples**

```r
require(stats)

## Very simple use
trace(sum)
hist(rnorm(100)) # shows about 3-4 calls to sum()
untrace(sum)

## Show how pt() is called from inside power.t.test():
if(FALSE)
  trace(pt) ## would show ~20 calls, but we want to see more:
  trace(pt, tracer = quote(cat(sprintf("tracing pt(*, ncp = %.15g)\n", ncp))),
              print = FALSE) # <- not showing typical extra
power.t.test(20, 1, power=0.8, sd=NULL) ##--> showing the ncp root finding:
```
f <- function(x, y) {
    y <- pmax(y, 0.001)
    if (x > 0) x ^ y else stop("x must be positive")
}

## arrange to call the browser on entering and exiting
## function f
trace("f", quote(browser(skipCalls = 4)),
       exit = quote(browser(skipCalls = 4)))

## instead, conditionally assign some data, and then browse
## on exit, but only then. Don’t bother me otherwise
trace("f", quote(if(any(y < 0)) yOrig <- y),
       exit = quote(if(exists("yOrig")) browser(skipCalls = 4)),
                   print = FALSE)

## Enter the browser just before stop() is called. First, find
## the step numbers
as.list(body(f))
as.list(body(f)[[3]])

## Now call the browser there
trace("f", quote(browser(skipCalls = 4)), at = list(c(3,4)))

## trace a utility function, with recover so we
## can browse in the calling functions as well.
trace("as.matrix", recover)

## turn off the tracing
untrace(c("f", "as.matrix"))

## Not run:
## trace calls to the function lm() that come from
## the nlme package.
## (The function nlme is in that package, and the package
## has a namespace, so the where= argument must be used
## to get the right version of lm)
trace(lm, exit = recover, where = asNamespace("nlme"))

## End(Not run)

---

**traceback**  
*Get and Print Call Stacks*
Description

By default traceback() prints the call stack of the last uncaught error, i.e., the sequence of calls that lead to the error. This is useful when an error occurs with an unidentifiable error message. It can also be used to print the current stack or arbitrary lists of deparsed calls.

`.traceback()` now returns the above call stack (and `traceback(x, *)` can be regarded as convenience function for printing the result of `.traceback()`).

Usage

```r
traceback(x = NULL, max.lines = getOption("deparse.max.lines"))
.traceback(x = NULL)
```

Arguments

- `x` NULL (default, meaning `.Traceback`), or an integer count of calls to skip in the current stack, or a list or pairlist of deparsed calls. See the details.
- `max.lines` The maximum number of lines to be printed per call. The default is unlimited.

Details

The default display is of the stack of the last uncaught error as stored as a list of deparsed calls in `.Traceback`, which traceback prints in a user-friendly format. The stack of deparsed calls always contains all function calls and all foreign function calls (such as `.Call`): if profiling is in progress it will include calls to some primitive functions. (Calls to builtins are included, but not to specials.) Errors which are caught via `try` or `tryCatch` do not generate a traceback, so what is printed is the call sequence for the last uncaught error, and not necessarily for the last error.

If `x` is numeric, then the current stack is printed, skipping `x` entries at the top of the stack. For example, `options(error = function() traceback(2))` will print the stack at the time of the error, skipping the call to `traceback()` and the error function that called it.

Otherwise, `x` is assumed to be a list or pairlist of deparsed calls and will be displayed in the same way.

Value

`traceback()` prints the deparsed call stack deepest call first, and returns it invisibly. The calls may print on more than one line, and the first line for each call is labelled by the frame number. The number of lines printed per call can be limited via `max.lines`.

Warning

It is undocumented where `.Traceback` is stored nor that it is visible, and this is subject to change.

References

Examples

```r
foo <- function(x) { print(1); bar(2) }
bar <- function(x) { x + a.variable.which.does.not.exist }
## Not run:
foo(2) # gives a strange error
traceback()
## End(Not run)
## 2: bar(2)
## 1: foo(2)
bar
## Ah, this is the culprit ...
## This will print the stack trace at the time of the error.
options(error = function() traceback(2))
```

```
tracemem  Trace Copying of Objects
```

Description

This function marks an object so that a message is printed whenever the internal code copies the object. It is a major cause of hard-to-predict memory use in R.

Usage

```r
tracemem(x)
untracemem(x)
retracemem(x, previous = NULL)
```

Arguments

- `x` An R object, not a function or environment or `NULL`.
- `previous` A value as returned by `tracemem` or `retracemem`.

Details

This functionality is optional, determined at compilation, because it makes R run a little more slowly even when no objects are being traced. `tracemem` and `untracemem` give errors when R is not compiled with memory profiling; `retracemem` does not (so it can be left in code during development).

It is enabled in the CRAN macOS and Windows builds of R.

When an object is traced any copying of the object by the C function `duplicate` produces a message to standard output, as does type coercion and copying when passing arguments to `.C` or `.Fortran`.

The message consists of the string `tracemem`, the identifying strings for the object being copied and the new object being created, and a stack trace showing where the duplication occurred. `retracemem()` is used to indicate that a variable should be considered a copy of a previous variable (e.g., after subscripting).

The messages can be turned off with `tracingState`.

It is not possible to trace functions, as this would conflict with `trace` and it is not useful to trace `NULL`, environments, promises, weak references, or external pointer objects, as these are not duplicated.

These functions are `primitive`.

---

**tracemem**

Tracemem

Trace Copying of Objects

This function marks an object so that a message is printed whenever the internal code copies the object. It is a major cause of hard-to-predict memory use in R.

Usage

```r
tracemem(x)
untracemem(x)
retracemem(x, previous = NULL)
```

Arguments

- `x` An R object, not a function or environment or `NULL`.
- `previous` A value as returned by `tracemem` or `retracemem`.

Details

This functionality is optional, determined at compilation, because it makes R run a little more slowly even when no objects are being traced. `tracemem` and `untracemem` give errors when R is not compiled with memory profiling; `retracemem` does not (so it can be left in code during development).

It is enabled in the CRAN macOS and Windows builds of R.

When an object is traced any copying of the object by the C function `duplicate` produces a message to standard output, as does type coercion and copying when passing arguments to `.C` or `.Fortran`.

The message consists of the string `tracemem`, the identifying strings for the object being copied and the new object being created, and a stack trace showing where the duplication occurred. `retracemem()` is used to indicate that a variable should be considered a copy of a previous variable (e.g., after subscripting).

The messages can be turned off with `tracingState`.

It is not possible to trace functions, as this would conflict with `trace` and it is not useful to trace `NULL`, environments, promises, weak references, or external pointer objects, as these are not duplicated.

These functions are `primitive`. 
Value

A character string for identifying the object in the trace output (an address in hex enclosed in angle brackets), or NULL (invisibly).

tracemem(d)
lm(d ~ a+log(b))

## f is not a copy and is not traced
f <- d[-1]
f+1
## indicate that f should be traced as a copy of d
retracemem(f, retracemem(d))
f+1

## End(Not run)

transform

Transform an Object, for Example a Data Frame

Description

transform is a generic function, which—at least currently—only does anything useful with data frames. transform.default converts its first argument to a data frame if possible and calls transform.data.frame.

Usage

transform(\_data\, ...)  

Arguments

\_data  The object to be transformed

...  Further arguments of the form tag=value
Details

The arguments to transform.data.frame are tagged vector expressions, which are evaluated in the data frame _data_. The tags are matched against names(_data_), and for those that match, the value replace the corresponding variable in _data_, and the others are appended to _data_.

Value

The modified value of _data_.

Warning

This is a convenience function intended for use interactively. For programming it is better to use the standard subsetting arithmetic functions, and in particular the non-standard evaluation of argument transform can have unanticipated consequences.

Note

If some of the values are not vectors of the appropriate length, you deserve whatever you get!

Trig

Trigonometric Functions

Description

These functions give the obvious trigonometric functions. They respectively compute the cosine, sine, tangent, arc-cosine, arc-sine, arc-tangent, and the two-argument arc-tangent. cospi(x), sinpi(x), and tanpi(x), compute cos(pi*x), sin(pi*x), and tan(pi*x).
Usage

\[
\begin{align*}
\cos(x) \\
\sin(x) \\
\tan(x) \\
\acos(x) \\
\asin(x) \\
\atan(x) \\
\atan2(y, x) \\
\cospi(x) \\
\sinpi(x) \\
\tanpi(x)
\end{align*}
\]

Arguments

\[x, y\] numeric or complex vectors.

Details

The arc-tangent of two arguments \( \atan2(y, x) \) returns the angle between the x-axis and the vector from the origin to \((x, y)\), i.e., for positive arguments \( \atan2(y, x) = \atan(y/x) \).

Angles are in radians, not degrees, for the standard versions (i.e., a right angle is \( \pi/2 \)), and in ‘half-rotations’ for \( \cospi \) etc.

\( \cospi(x), \sinpi(x), \) and \( \tanpi(x) \) are accurate for \( x \) values which are multiples of a half.

All except \( \atan2 \) are internal generic primitive functions: methods can be defined for them individually or via the \texttt{Math} group generic.

These are all wrappers to system calls of the same name (with prefix \texttt{c} for complex arguments) where available. (\texttt{cospi}, \texttt{sinpi}, and \texttt{tanpi} are part of a C11 extension and provided by e.g. macOS and Solaris: where not yet available call to \texttt{cos} etc are used, with special cases for multiples of a half.)

Value

\( \tanpi(0.5) \) is \texttt{NaN}. Similarly for other inputs with fractional part \( 0.5 \).

Complex values

For the inverse trigonometric functions, branch cuts are defined as in Abramowitz and Stegun, figure 4.4, page 79.

For \( \asin \) and \( \acos \), there are two cuts, both along the real axis: \((-\infty, -1] \) and \([1, \infty) \).

For \( \atan \) there are two cuts, both along the pure imaginary axis: \((-\infty i, -1i] \) and \([1i, \infty i) \).

The behaviour actually on the cuts follows the C99 standard which requires continuity coming round the endpoint in a counter-clockwise direction.

Complex arguments for \( \cospi, \sinpi, \) and \( \tanpi \) are not yet implemented, and they are a ‘future direction’ of ISO/IEC TS 18661-4.

S4 methods

All except \( \atan2 \) are S4 generic functions: methods can be defined for them individually or via the \texttt{Math} group generic.

options(op)
```

trimws

Remove Leading/Trailing Whitespace

Description

Remove leading and/or trailing whitespace from character strings.

Usage

```R
trimws(x, which = c("both", "left", "right"))
```

Arguments

- `x`: a character vector
- `which`: a character string specifying whether to remove both leading and trailing whitespace (default), or only leading ("left") or trailing ("right"). Can be abbreviated.

Details

For portability, ‘whitespace’ is taken as the character class `[ \t\r\n]` (space, horizontal tab, line feed, carriage return).

Examples

```R
x <- " Some text. 
trimws(x)
trimws(x, "l")
trimws(x, "r")
```
try

Try an Expression Allowing Error Recovery

Description

try is a wrapper to run an expression that might fail and allow the user’s code to handle error-recovery.

Usage

```r
try(expr, silent = FALSE,
    outFile = getOption("try.outFile", default = stderr()))
```

Arguments

- `expr`: an R expression to try.
- `silent`: logical: should the report of error messages be suppressed?
- `outFile`: a connection, or a character string naming the file to print to (via `cat(*, file = outFile)`); used only if `silent` is false, as by default.

Details

try evaluates an expression and traps any errors that occur during the evaluation. If an error occurs then the error message is printed to the stderr connection unless `options("show.error.messages")` is false or the call includes `silent = TRUE`. The error message is also stored in a buffer where it can be retrieved by `geterrmessage`. (This should not be needed as the value returned in case of an error contains the error message.)

try is implemented using `tryCatch`; for programming, instead of `try(expr, silent = TRUE)`, something like `tryCatch(expr, error = function(e) e)` (or other simple error handler functions) may be more efficient and flexible.

It may be useful to set the default for `outFile` to `stdout()`, i.e.,

```r
options(try.outFile = stdout())
```

instead of the default `stderr()`, notably when `try()` is used inside a Sweave code chunk and the error message should appear in the resulting document.

Value

The value of the expression if `expr` is evaluated without error, but an invisible object of class "try-error" containing the error message, and the error condition as the "condition" attribute, if it fails.

See Also

- `options` for setting error handlers and suppressing the printing of error messages; `geterrmessage` for retrieving the last error message. The underlying `tryCatch` provides more flexible means of catching and handling errors.
- `assertCondition` in package `tools` is related and useful for testing.
Examples

```r
## this example will not work correctly in example(try), but
## it does work correctly if pasted in
options(show.error.messages = FALSE)
try(log("a"))
print(.Last.value)
options(show.error.messages = TRUE)

## alternatively,
print(try(log("a"), TRUE))

## run a simulation, keep only the results that worked.
set.seed(123)
x <- stats::rnorm(50)
doit <- function(x)
{
  x <- sample(x, replace = TRUE)
  if(length(unique(x)) > 30) mean(x)
  else stop("too few unique points")
}
## alternative 1
res <- lapply(1:100, function(i) try(doit(x), TRUE))
## alternative 2
## Not run: res <- vector("list", 100)
for(i in 1:100) res[[i]] <- try(doit(x), TRUE)
## End(Not run)
unlist(res[sapply(res, function(x) !inherits(x, "try-error"))])
```

typeof

The Type of an Object

Description
typeof determines the (R internal) type or storage mode of any object

Usage
`typeof(x)`

Arguments

x
any R object.

Value
A character string. The possible values are listed in the structure TypeTable in `src/main/util.c`. Current values are the vector types "logical", "integer", "double", "complex", "character", 
"raw" and "list", "NULL", "closure" (function), "special" and "builtin" (basic functions and operators), "environment", "S4" (some S4 objects) and others that are unlikely to be seen at user level ("symbol", "pairlist", "promise", "language", "char", "...", "any", "expression", "externalptr", "bytecode" and "weakref").
See Also

mode, storage.mode.

isS4 to determine if an object has an S4 class.

Examples

typeof(2)
mode(2)

unique  Extract Unique Elements

Description

unique returns a vector, data frame or array like x but with duplicate elements/rows removed.

Usage

unique(x, incomparables = FALSE, ...)

## Default S3 method:
unique(x, incomparables = FALSE, fromLast = FALSE,
        nmax = NA, ...)

## S3 method for class 'matrix'
unique(x, incomparables = FALSE, MARGIN = 1,
        fromLast = FALSE, ...)

## S3 method for class 'array'
unique(x, incomparables = FALSE, MARGIN = 1,
        fromLast = FALSE, ...)

Arguments

x  a vector or a data frame or an array or NULL.
incomparables  a vector of values that cannot be compared. FALSE is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as x.
fromLast  logical indicating if duplication should be considered from the last, i.e., the last (or rightmost) of identical elements will be kept. This only matters for names or dimnames.
nmax  the maximum number of unique items expected (greater than one). See duplicated.
...  arguments for particular methods.
MARGIN  the array margin to be held fixed: a single integer.
**Details**

This is a generic function with methods for vectors, data frames and arrays (including matrices). The array method calculates for each element of the dimension specified by `MARGIN` if the remaining dimensions are identical to those for an earlier element (in row-major order). This would most commonly be used for matrices to find unique rows (the default) or columns (with `MARGIN = 2`).

Note that unlike the Unix command `uniq` this omits *duplicated* and not just *repeated* elements/rows. That is, an element is omitted if it is equal to any previous element and not just if it is equal the immediately previous one. (For the latter, see `rle`).

Missing values ("NA") are regarded as equal, numeric and complex ones differing from NaN; character strings will be compared in a "common encoding"; for details, see `match` (and `duplicated`) which use the same concept.

Values in `incomparables` will never be marked as duplicated. This is intended to be used for a fairly small set of values and will not be efficient for a very large set.

When used on a data frame with more than one column, or an array or matrix when comparing dimensions of length greater than one, this tests for identity of character representations. This will catch people who unwisely rely on exact equality of floating-point numbers!

**Value**

For a vector, an object of the same type of `x`, but with only one copy of each duplicated element. No attributes are copied (so the result has no names).

For a data frame, a data frame is returned with the same columns but possibly fewer rows (and with row names from the first occurrences of the unique rows).

A matrix or array is subsetted by `[, drop = FALSE]`, so dimensions and dimnames are copied appropriately, and the result always has the same number of dimensions as `x`.

**Warning**

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see `vector`) or differ only in their attributes. In the worst case it is $O(n^2)$.

**References**

**See Also**

duplicated which gives the indices of duplicated elements.

rle which is the equivalent of the Unix uniq -c command.

**Examples**

```r
x <- c(3:5, 11:8, 8 + 0:5)
(ux <- unique(x))
(u2 <- unique(x, fromLast = TRUE)) # different order
stopifnot(identical(sort(ux), sort(u2)))

length(unique(sample(100, 100, replace = TRUE)))
## approximately 100(1 - 1/e) = 63.21

unique(iris)
```
unlink

Delete Files and Directories

Description

unlink deletes the file(s) or directories specified by x.

Usage

unlink(x, recursive = FALSE, force = FALSE)

Arguments

x a character vector with the names of the file(s) or directories to be deleted. Wildcards (normally '*' and '?') are allowed.

recursive logical. Should directories be deleted recursively?

force logical. Should permissions be changed (if possible) to allow the file or directory to be removed?

Details

Tilde-expansion (see path.expand) is done on x.

If recursive = FALSE directories are not deleted, not even empty ones.

On most platforms 'file' includes symbolic links, fifos and sockets.

unlink(x, recursive = TRUE) deletes the just symbolic link if the target of such a link is a directory.

Wildcard expansion is done by the internal code of Sys.glob. Wildcards never match a leading '.' in the filename, and files '.', and '..' will never be considered for deletion. Wildcards will only be expanded if the system supports it. Most systems will support not only '*' and '?' but also character classes such as '[a-z]' (see the man pages for the system call glob on your OS).

The metacharacters * ? [ can occur in Unix filenames, and this makes it difficult to use unlink to delete such files (see file.remove), although escaping the metacharacters by backslashes usually works. If a metacharacter matches nothing it is considered as a literal character.

recursive = TRUE might not be supported on all platforms, when it will be ignored, with a warning: however there are no known current examples.

Value

0 for success, 1 for failure, invisibly. Not deleting a non-existent file is not a failure, nor is being unable to delete a directory if recursive = FALSE. However, missing values in x are regarded as failures.

References

See Also

file.remove.
Description

Given a list structure \( x \), `unlist` simplifies it to produce a vector which contains all the atomic components which occur in \( x \).

Usage

```r
unlist(x, recursive = TRUE, use.names = TRUE)
```

Arguments

- **x**: an \( R \) object, typically a list or vector.
- **recursive**: logical. Should unlisting be applied to list components of \( x \)?
- **use.names**: logical. Should names be preserved?

Details

`unlist` is generic: you can write methods to handle specific classes of objects, see `InternalMethods`, and note, e.g., `relist` with the `unlist` method for `relistable` objects.

If `recursive = FALSE`, the function will not recurse beyond the first level items in \( x \).

Factors are treated specially. If all non-list elements of \( x \) are factors (or ordered factors) then the result will be a factor with levels the union of the level sets of the elements, in the order the levels occur in the level sets of the elements (which means that if all the elements have the same level set, that is the level set of the result).

\( x \) can be an atomic vector, but then `unlist` does nothing useful, not even drop names.

By default, `unlist` tries to retain the naming information present in \( x \). If `use.names = FALSE` all naming information is dropped.

Where possible the list elements are coerced to a common mode during the unlisting, and so the result often ends up as a character vector. Vectors will be coerced to the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`: pairlists are treated as lists.

A list is a (generic) vector, and the simplified vector might still be a list (and might be unchanged). Non-vector elements of the list (for example language elements such as names, formulas and calls) are not coerced, and so a list containing one or more of these remains a list. (The effect of unlisting an `lm` fit is a list which has individual residuals as components.) Note that `unlist(x)` now returns \( x \) unchanged also for non-vector \( x \), instead of signalling an error in that case.

Value

`NULL` or an expression or a vector of an appropriate mode to hold the list components.

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < double < complex < character < list < expression`, after coercion of pairlists to lists.
References

c, as.list, relist.

Examples

unlist(options())
unlist(options(), use.names = FALSE)

l.ex <- list(a = list(1:5, LETTERS[1:5]), b = "Z", c = NA)
unlist(l.ex, recursive = FALSE)
unlist(l.ex, recursive = TRUE)

l1 <- list(a = "a", b = 2, c = pi+2i)
unlist(l1) # a character vector
l2 <- list(a = "a", b = as.name("b"), c = pi+2i)
unlist(l2) # remains a list

ll <- list(as.name("sinc"), quote( a + b ), 1:10, letters, expression(1+x))
utils::str(ll)
for(x in ll)
  stopifnot(identical(x, unlist(x)))

---

**unname**

*Remove names or dimnames*

Description

Remove the `names` or `dimnames` attribute of an `R` object.

Usage

`unname(obj, force = FALSE)`

Arguments

- **obj**: an `R` object.
- **force**: logical; if true, the `dimnames` (names and row names) are removed even from `data.frames`.

Value

Object as `obj` but without `names` or `dimnames`.  

Examples

```r
require(graphics); require(stats)

## Answering a question on R-help (14 Oct 1999):
col3 <- 750 + 100*rt(1500, df = 3)
breaks <- factor(cut(col3, breaks = 360+5*(0:155)))
z <- table(breaks)
z[1:5]  # The names are larger than the data ...
barplot(unname(z), axes = FALSE)
```

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class(es) of the first argument to the generic function or of the object supplied as an argument to `UseMethod` or `NextMethod`.

Usage

```r
UseMethod(generic, object)

NextMethod(generic = NULL, object = NULL, ...)
```

Arguments

generic a character string naming a function (and not a built-in operator). Required for `UseMethod`.

object for `UseMethod`: an object whose class will determine the method to be dispatched. Defaults to the first argument of the enclosing function.

... further arguments to be passed to the next method.

Details

An R object is a data object which has a class attribute (and this can be tested by `is.object`). A class attribute is a character vector giving the names of the classes from which the object inherits. If the object does not have a class attribute, it has an implicit class. Matrices and arrays have class "matrix" or "array" followed by the class of the underlying vector. Most vectors have class the result of `mode(x)`, except that integer vectors have class c("integer", "numeric") and real vectors have class c("double", "numeric").

When a function calling `UseMethod("fun")` is applied to an object with class attribute c("first", "second"), the system searches for a function called fun.first and, if it finds it, applies it to the object. If no such function is found a function called fun.default is used, if it exists, or an error results.

Function methods can be used to find out about the methods for a particular generic function or class.

`UseMethod` is a primitive function but uses standard argument matching. It is not the only means of dispatch of methods, for there are internal generic and group generic functions. UseMethod
UseMethod currently dispatches on the implicit class even for arguments that are not objects, but the other means of dispatch do not.

NextMethod invokes the next method (determined by the class vector, either of the object supplied to the generic, or of the first argument to the function containing NextMethod if a method was invoked directly). Normally NextMethod is used with only one argument, generic, but if further arguments are supplied these modify the call to the next method.

NextMethod should not be called except in methods called by UseMethod or from internal generics (see InternalGenerics). In particular it will not work inside anonymous calling functions (e.g., get("print.ts")(AirPassengers)).

Namespaces can register methods for generic functions. To support this, UseMethod and NextMethod search for methods in two places: first in the environment in which the generic function is called, and then in the registration data base for the environment in which the generic is defined (typically a namespace). So methods for a generic function need to be available in the environment of the call to the generic, or they must be registered. (It does not matter whether they are visible in the environment in which the generic is defined.)

Technical Details

Now for some obscure details that need to appear somewhere. These comments will be slightly different than those in Chambers(1992). (See also the draft ‘R Language Definition’.) UseMethod creates a new function call with arguments matched as they came in to the generic. Any local variables defined before the call to UseMethod are retained (unlike S). Any statements after the call to UseMethod will not be evaluated as UseMethod does not return. UseMethod can be called with more than two arguments: a warning will be given and additional arguments ignored. (They are not completely ignored in S.) If it is called with just one argument, the class of the first argument of the enclosing function is used as object: unlike S this is the first actual argument passed and not the current value of the object of that name.

NextMethod works by creating a special call frame for the next method. If no new arguments are supplied, the arguments will be the same in number, order and name as those to the current method but their values will be promises to evaluate their name in the current method and environment. Any named arguments matched to ... are handled specially: they either replace existing arguments of the same name or are appended to the argument list. They are passed on as the promise that was supplied as an argument to the current environment. (S does this differently!) If they have been evaluated in the current (or a previous environment) they remain evaluated. (This is a complex area, and subject to change: see the draft ‘R Language Definition’.)

The search for methods for NextMethod is slightly different from that for UseMethod. Finding no fun.default is not necessarily an error, as the search continues to the generic itself. This is to pick up an internal generic like [ which has no separate default method, and succeeds only if the generic is a primitive function or a wrapper for a .Internal function of the same name. (When a primitive is called as the default method, argument matching may not work as described above due to the different semantics of primitives.)

You will see objects such as .Generic, .Method, and .Class used in methods. These are set in the environment within which the method is evaluated by the dispatch mechanism, which is as follows:

1. Find the context for the calling function (the generic): this gives us the unevaluated arguments for the original call.
2. Evaluate the object (usually an argument) to be used for dispatch, and find a method (possibly the default method) or throw an error.
3. Create an environment for evaluating the method and insert special variables (see below) into that environment. Also copy any variables in the environment of the generic that are not formal (or actual) arguments.
4. Fix up the argument list to be the arguments of the call matched to the formals of the method.

.Generic is a length-one character vector naming the generic function.
.Method is a character vector (normally of length one) naming the method function. (For functions in the group generic Ops it is of length two.)
.Class is a character vector of classes used to find the next method. NextMethod adds an attribute "previous" to .Class giving the .Class last used for dispatch, and shifts .Class along to that used for dispatch.
.GenericCallEnv and .GenericDefEnv are the environments of the call to be generic and defining the generic respectively. (The latter is used to find methods registered for the generic.)

Note that .Class is set when the generic is called, and is unchanged if the class of the dispatching argument is changed in a method. It is possible to change the method that NextMethod would dispatch by manipulating .Class, but 'this is not recommended unless you understand the inheritance mechanism thoroughly' (Chambers & Hastie, 1992, p. 469).

Note
This scheme is called S3 (S version 3). For new projects, it is recommended to use the more flexible and robust S4 scheme provided in the methods package.

---

### userhooks

**Functions to Get and Set Hooks for Load, Attach, Detach and Unload**

**Description**

These functions allow users to set actions to be taken before packages are attached/detached and namespaces are (un)loaded.

**Usage**

```r
getchook(hookName)

sethook(hookName, value,
    action = c("append", "prepend", "replace"))

packageEvent(pkgname,
    event = c("onLoad", "attach", "detach", "onUnload"))
```
Arguments

hookName  character string: the hook name
pkgname   character string: the package/namespace name
event     character string: an event for the package. Can be abbreviated.
value     A function or a list of functions, or for action = "replace", NULL
action    The action to be taken. Can be abbreviated.

Details

setHook provides a general mechanism for users to register hooks, a list of functions to be called from system (or user) functions. The initial set of hooks was associated with events on packages/namespaces: these hooks are named via calls to packageEvent.

To remove a hook completely, call setHook(hookName, NULL, "replace").

When an R package is attached by library or loaded by other means, it can call initialization code. See .onLoad for a description of the package hook functions called during initialization. Users can add their own initialization code via the hooks provided by setHook(), functions which will be called as funname(pkgname, pkgpath) inside a try call.

The sequence of events depends on which hooks are defined, and whether a package is attached or just loaded. In the case where all hooks are defined and a package is attached, the order of initialization events is as follows:

1. The package namespace is loaded.
2. The package's .onLoad function is run.
3. If S4 methods dispatch is on, any actions set by setLoadAction are run.
4. The namespace is sealed.
5. The user's "onLoad" hook is run.
6. The package is added to the search path.
7. The package's .onAttach function is run.
8. The package environment is sealed.
9. The user's "attach" hook is run.

A similar sequence (but in reverse) is run when a package is detached and its namespace unloaded:

1. The user's "detach" hook is run.
2. The package's .Last.lib function is run.
3. The package is removed from the search path.
4. The user's "onUnload" hook is run.
5. The package's .onUnload function is run.
6. The package namespace is unloaded.

Note that when an R session is finished, packages are not detached and namespaces are not unloaded, so the corresponding hooks will not be run.

Also note that some of the user hooks are run without the package being on the search path, so in those hooks objects in the package need to be referred to using the double (or triple) colon operator, as in the example.

If multiple hooks are added, they are normally run in the order shown by getHook, but the "detach" and "onUnload" hooks are run in reverse order so the default for package events is to add hooks ‘inside’ existing ones.

The hooks are stored in the environment .userHooksEnv in the base package, with ‘mangled’ names.
For `getHook` function, a list of functions (possibly empty). For `setHook` function, no return value. For packageEvent, the derived hook name (a character string).

**Note**

Hooks need to be set before the event they modify: for standard packages this can be problematic as `methods` is loaded and attached early in the startup sequence. The usual place to set hooks such as the example below is in the `.Rprofile` file, but that will not work for `methods`.

**See Also**

`library`, `detach`, `loadNamespace`.

See `::` for a discussion of the double and triple colon operators.

Other hooks may be added later: functions `plot.new` and `persp` already have them.

**Examples**

```r
setHook(packageEvent("grDevices", "onLoad"),
         function(...) grDevices::ps.options(horizontal = FALSE))
```

---

**utf8Conversion**

**Convert Integer Vectors to or from UTF-8-encoded Character Vectors**

**Description**

Conversion of UTF-8 encoded character vectors to and from integer vectors representing a UTF-32 encoding.

**Usage**

```r
utf8ToInt(x)
intToUtf8(x, multiple = FALSE, allow_surrogate_pairs = FALSE)
```

**Arguments**

- `x` object to be converted.
- `multiple` logical: should the conversion be to a single character string or multiple individual characters?
- `allow_surrogate_pairs` logical: should interpretation of surrogate pairs be attempted? (See ‘Details’.) Only supported for `multiple = FALSE` and in R 3.5.0 and later.
Details

These will work in any locale, including on platforms that do not otherwise support multi-byte character sets.

Unicode defines a name and a number of all of the glyphs it encompasses: the numbers are called code points: since RFC3629 they run from \(0\) to \(0x10FFFF\) (with about 12% being assigned by version 10.0 of the Unicode standard).

`intToUtf8` does not by default handle surrogate pairs: inputs in the surrogate ranges are mapped to NA. They might occur if a UTF-16 byte stream has been read as 2-byte integers (in the correct byte order), in which case `allow_surrogate_pairs = TRUE` will try to interpret them (with unmatched surrogate values still treated as NA).

Value

`utf8ToInt` converts a length-one character string encoded in UTF-8 to an integer vector of Unicode code points.

`intToUtf8` converts a numeric vector of Unicode code points either (default) to a single character string or a character vector of single characters. Non-integral numeric values are truncated to integers. For output to a single character string \(0\) is silently omitted: otherwise \(0\) is mapped to "". The Encoding of a non-NA return value is declared as "UTF-8".

Invalid and NA inputs are mapped to NA output.

Validity

Which code points are regarded as valid has changed over the lifetime of UTF-8. Originally all 32-bit unsigned integers were potentially valid and could be converted to up to 6 bytes in UTF-8. Since 2003 it has been stated that there will never be valid code points larger than \(0x10FFFF\), and so valid UTF-8 encodings are never more than 4 bytes.

The code points in the surrogate-pair range \(0xD000\) to \(0xDFFF\) are prohibited in UTF-8 and so are regarded as invalid by `utf8ToInt` and by default by `intToUtf8`.

The position of ‘noncharacters’ (notably \(0xFFFE\) and \(0xFFFF\)) was clarified by ‘Corrigendum 9’ in 2013. These are valid but will never be given an official interpretation. (In some earlier versions of R `utf8ToInt` treated them as invalid.)

References

Examples

```r
## will only display in some locales and fonts
intToUtf8(0x03B2L) # Greek beta
utf8ToInt("bi\u00dfchen")
utf8ToInt("\xfa\xb4\xbfb\x9f")

## A valid UTF-16 surrogate pair (for U+10437)
x <- c(0x0081, 0xDC37)
intToUtf8(x)
intToUtf8(x, TRUE)
(xx <- intToUtf8(x, TRUE)) # will only display in some locales and fonts
charToRaw(xx)
```
validUTF8

## Not run: ## An example of how surrogate pairs might occur
x <- "\U10437"
charToRaw(x)
foo <- tempfile()
writeLines(x, file(foo, encoding = "UTF-16LE"))
## next two are OS-specific, but are mandated by POSIX
system(paste("od -x", foo)) # 2-byte units, correct on little-endian platform
system(paste("od -t x1", foo)) # single bytes as hex
y <- readBin(foo, "integer", 2, 2, FALSE, endian = "little")
sprintf("%X", y)
intToUtf8(y, , TRUE)
## End(Not run)

validUTF8 Check if a Character Vector is Validly Encoded

Description
Check if each element of a character vector is valid in its implied encoding.

Usage
validUTF8(x)
validEnc(x)

Arguments
x A character vector.

Details
These use similar checks to those used by functions such as grep.
validUTF8 ignores any marked encoding (see Encoding) and so looks directly if the bytes in each string are valid UTF-8.
validEnc regards character strings as validly encoded unless their encodings are marked as UTF-8 or they are unmarked and the R session is in a UTF-8 or other multi-byte locale. (The checks in other multi-byte locales depend on the OS and as with iconv not all invalid inputs may be detected.)

Value
A logical vector of the same length as x. NA elements are regarded as validly encoded.

Note
It would be possible to check for the validity of character strings in a Latin-1 encoding, but extensions such as CP1252 are widely accepted as ‘Latin-1’ and 8-bit encodings rarely need to be checked for validity.
Examples

```r
x <-
## from example(text)
c("Jetz", "no", "chli", "\Z\xc3\xbcrit\xc3\xbcbc\xc3\xbctsch:\", 
   "(noch", "ein", "\bi\xc3\x9fchen", "\Z\xc3\xbc", "deutsch"), 
## from a CRAN check log
   "\xfa\xb4\xbf\xbf\x9f")
validUTF8(x)
validEnc(x) # depends on the locale
Encoding(x) <-"UTF-8"
validEnc(x)
```

Description

vector produces a vector of the given length and mode.

as.vector, a generic, attempts to coerce its argument into a vector of mode mode (the default is to coerce to whichever vector mode is most convenient): if the result is atomic all attributes are removed.

is.vector returns TRUE if x is a vector of the specified mode having no attributes other than names. It returns FALSE otherwise.

Usage

```r
vector(mode = "logical", length = 0)
as.vector(x, mode = "any")
is.vector(x, mode = "any")
```

Arguments

- **mode**: character string naming an atomic mode or "list" or "expression" or (except for vector) "any". Currently, is.vector() allows any type (see typeof) for mode, and when mode is not "any", is.vector(x, mode) is almost the same as typeof(x) == mode.
- **length**: a non-negative integer specifying the desired length. For a long vector, i.e., length > .Machine$integer.max, it has to be of type "double". Supplying an argument of length other than one is an error.
- **x**: an R object.

Details

The atomic modes are "logical", "integer", "numeric" (synonym "double"), "complex", "character" and "raw".

If mode = "any", is.vector may return TRUE for the atomic modes, list and expression. For any mode, it will return FALSE if x has any attributes except names. (This is incompatible with S.) On the other hand, as.vector removes all attributes including names for results of atomic mode (but not those of mode "list" nor "expression").

Note that factors are not vectors; is.vector returns FALSE and as.vector converts a factor to a character vector for mode = "any".
Value

For `vector`, a vector of the given length and mode. Logical vector elements are initialized to `FALSE`, numeric vector elements to 0, character vector elements to "", raw vector elements to null bytes and list/expression elements to `NULL`.

For `as.vector`, a vector (atomic or of type list or expression). All attributes are removed from the result if it is of an atomic mode, but not in general for a list result. The default method handles 24 input types and 12 values of type: the details of most coercions are undocumented and subject to change.

For `is.vector`, TRUE or FALSE. `is.vector(x, mode = "numeric")` can be true for vectors of types "integer" or "double" whereas `is.vector(x, mode = "double")` can only be true for those of type "double".

Methods for `as.vector()`

Writers of methods for `as.vector` need to take care to follow the conventions of the default method. In particular

- Argument `mode` can be "any", any of the atomic modes, "list", "expression", "symbol", "pairlist" or one of the aliases "double" and "name".
- The return value should be of the appropriate mode. For `mode = "any"` this means an atomic vector or list.
- Attributes should be treated appropriately: in particular when the result is an atomic vector there should be no attributes, not even names.
- `is.vector(as.vector(x, m), m)` should be true for any mode `m`, including the default "any".

Note

`as.vector` and `is.vector` are quite distinct from the meaning of the formal class "vector" in the `methods` package, and hence `as(x, "vector")` and `is(x, "vector")`.

Note that `as.vector(x)` is not necessarily a null operation if `is.vector(x)` is true: any names will be removed from an atomic vector.

Non-vector modes "symbol" (synonym "name") and "pairlist" are accepted but have long been undocumented: they are used to implement `as.name` and `as.pairlist`, and those functions should preferably be used directly. None of the description here applies to those modes: see the help for the preferred forms.

`c`, `is.numeric`, `is.list`, etc.

Examples

def <- data.frame(x = 1:3, y = 5:7)
## Error: try(as.vector(data.frame(x = 1:3, y = 5:7), mode = "numeric"))
Vectorize

Vectorize creates a function wrapper that vectorizes the action of its argument FUN.

Usage

Vectorize(FUN, vectorize.args = arg.names, SIMPLIFY = TRUE,
USE.NAMES = TRUE)

Arguments

- **FUN**: function to apply, found via `match.fun`.
- **vectorize.args**: a character vector of arguments which should be vectorized. Defaults to all arguments of FUN.
- **SIMPLIFY**: logical or character string; attempt to reduce the result to a vector, matrix or higher dimensional array; see the simplify argument of `sapply`.
- **USE.NAMES**: logical; use names if the first ... argument has names, or if it is a character vector, use that character vector as the names.

Details

The arguments named in the `vectorize.args` argument to Vectorize are the arguments passed in the ... list to `mapply`. Only those that are actually passed will be vectorized; default values will not. See the examples.

Vectorize cannot be used with primitive functions as they do not have a value for `formals`.

It also cannot be used with functions that have arguments named FUN, vectorize.args, SIMPLIFY or USE.NAMES, as they will interfere with the Vectorize arguments. See the `combn` example below for a workaround.

Value

A function with the same arguments as FUN, wrapping a call to `mapply`.
Examples

# We use rep.int as rep is primitive
vrep <- Vectorize(rep.int)
vrep(1:4, 4:1)
vrep(times = 1:4, x = 4:1)

vrep <- Vectorize(rep.int, "times")
vrep(times = 1:4, x = 42)

f <- function(x = 1:3, y) c(x, y)
vf <- Vectorize(f, SIMPLIFY = FALSE)
f(1:3, 1:3)
vf(1:3, 1:3)
vf(y = 1:3) # Only vectorizes y, not x

# Nonlinear regression contour plot, based on nls() example
require(graphics)
SS <- function(Vm, K, resp, conc) {
    pred <- (Vm * conc)/(K + conc)
    sum((resp - pred)^2 / pred)
}
vSS <- Vectorize(SS, c("Vm", "K"))
Treated <- subset(Puromycin, state == "treated")

Vm <- seq(140, 310, length.out = 50)
K <- seq(0, 0.15, length.out = 40)
SSvals <- outer(Vm, K, vSS, Treated$rate, Treated$conc)
contour(Vm, K, SSvals, levels = (1:10)^2, xlab = "Vm", ylab = "K")

# combn() has an argument named FUN
combnV <- Vectorize(function(x, m, FUNV = NULL) combn(x, m, FUN = FUNV),
    vectorize.args = c("x", "m"))
combnV(4, 1:4)
combnV(4, 1:4, sum)

Description

Generates a warning message that corresponds to its argument(s) and (optionally) the expression or function from which it was called.

Usage

warning(..., call. = TRUE, immediate. = FALSE, noBreaks. = FALSE, domain = NULL)
suppressWarnings(expr)

Arguments

... zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
warning

call. logical, indicating if the call should become part of the warning message.
immediate. logical, indicating if the call should be output immediately, even if
getOption("warn") <= 0.
noBreaks. logical, indicating as far as possible the message should be output as a single
line when options(warn = 1).
expr expression to evaluate.
domain see gettext. If NA, messages will not be translated, see also the note in stop.

Details

The result depends on the value of options("warn") and on handlers established in the executing
code.

If a condition object is supplied it should be the only argument, and further arguments will be
ignored, with a message.

warning signals a warning condition by (effectively) calling signalCondition. If there are no
handlers or if all handlers return, then the value of warn = getOption("warn") is used to determine
the appropriate action. If warn is negative warnings are ignored; if it is zero they are stored and
printed after the top-level function has completed; if it is one they are printed as they occur and
if it is 2 (or larger) warnings are turned into errors. Calling warning(immediate. = TRUE) turns
warn <= 0 into warn = 1 for this call only.

If warn is zero (the default), a read-only variable last.warning is created. It contains the warnings
which can be printed via a call to warnings.

Warnings will be truncated to getOption("warning.length") characters, default 1000, indicated
by [... truncated].

While the warning is being processed, a muffleWarning restart is available. If this restart is invoked
with invokeRestart, then warning returns immediately.

An attempt is made to coerce other types of inputs to warning to character vectors.
suppressWarnings evaluates its expression in a context that ignores all warnings.

Value

The warning message as character string, invisibly.

References

Brooks/Cole.

See Also

stop for fatal errors, message for diagnostic messages, warnings, and options with argument
warn=.

ggettext for the mechanisms for the automated translation of messages.

Examples

testit <- function() warning("testit")
testit() ## shows call
testit <- function() warning("problem in testit", call. = FALSE)
testit() ## no call
suppressWarnings(warning("testit"))

warnings

Print Warning Messages

Description

warnings and its print method print the variable last.warning in a pleasing form.

Usage

warnings(...)

## S3 method for class 'warnings'
summary(object, ...)

## S3 method for class 'warnings'
print(x, tags,
       header = ngettext(n, "Warning message:
", "Warning messages:
"),
       ...)  

## S3 method for class 'summary.warnings'
print(x, ...)

Arguments

... arguments to be passed to cat (for warnings()).
object a "warnings" object as returned by warnings().
x a "warnings" or "summary.warnings" object.
tags if not missing, a character vector of the same length as x, to "label" the messages. Defaults to paste0(seq_len(n), " ", " ") for n ≥ 2 where n <- length(x).
header a character string cat()ed before the messages are printed.

Details

See the description of options("warn") for the circumstances under which there is a last.warning object and warnings() is used. In essence this is if options(warn = 0) and warning has been called at least once.

Note that the length(last.warning) is maximallygetOption("nwarnings") (at the time the warnings are generated) which is 50 by default. To increase, use something like

```R
options(nwarnings = 10000)
```

It is possible that last.warning refers to the last recorded warning and not to the last warning, for example if options(warn) has been changed or if a catastrophic error occurred.

Value

warnings() returns an object of S3 class "warnings", basically a named list.
summary(<warnings>) returns a "summary.warnings" object which is basically the list of unique warnings (unique(object)) with a "counts" attribute, somewhat experimentally.
weekdays

Extract Parts of a POSIXt or Date Object

Description

Extract the weekday, month or quarter, or the Julian time (days since some origin). These are
generic functions: the methods for the internal date-time classes are documented here.

Usage

weekdays(x, abbreviate)
## S3 method for class 'POSIXt'
weekdays(x, abbreviate = FALSE)
## S3 method for class 'Date'
weekdays(x, abbreviate = FALSE)

months(x, abbreviate)
## S3 method for class 'POSIXt'
months(x, abbreviate = FALSE)

Warning

It is undocumented where last.warning is stored nor that it is visible, and this is subject to change.

References

Brooks/Cole.

See Also

warning.

Examples

## NB this example is intended to be pasted in,
## rather than run by example()
ow <- options("warn")
for(w in -1:1) {
    options(warn = w); cat("\n warn =", w, "\n")
    for(i in 1:3) { cat(i,"..\n"); m <- matrix(1:7, 3, 4) }
    cat("---------\n")
}## at the end prints all three warnings, from the 'option(warn = 0)' above
options(ow) # reset to previous, typically 'warn = 0'
tail(warnings(), 2) # see the last two warnings only (via '[' method)

## Often the most useful way to look at many warnings:
summary(warnings())
op <- options(nwarnings = 10000) ## <- get "full statistics"
x <- 1:36; for(n in 1:13) for(m in 1:12) A <- matrix(x, n,m) # There were 105 warnings ...
summary(warnings())
options(op) # revert to previous (keeping 50 messages by default)
## S3 method for class 'Date'
months(x, abbreviate = FALSE)

quarters(x, abbreviate)
## S3 method for class 'POSIXt'
quarters(x, ...)
## S3 method for class 'Date'
quarters(x, ...)

julian(x, ...)
## S3 method for class 'POSIXt'
julian(x, origin = as.POSIXct("1970-01-01", tz = "GMT"), ...)
## S3 method for class 'Date'
julian(x, origin = as.Date("1970-01-01"), ...)

### Arguments

- **x**
a  
an object inheriting from class "POSIXt" or "Date".

- **abbreviate**
  
  logical vector (possibly recycled). Should the names be abbreviated?

- **origin**
  
  an length-one object inheriting from class "POSIXt" or "Date".

- **...**
  
  arguments for other methods.

### Value

- **weekdays** and **months** return a character vector of names in the locale in use.

- **quarters** returns a character vector of "Q1" to "Q4".

- **julian** returns the number of days (possibly fractional) since the origin, with the origin as a "origin" attribute. All time calculations in R are done ignoring leap-seconds.

### Note

Other components such as the day of the month or the year are very easy to compute: just use **as.POSIXlt** and extract the relevant component. Alternatively (especially if the components are desired as character strings), use **strftime**.

### See Also

- [DateTimeClasses](#)
- [Date](#)

### Examples

```r
weekdays(.leap.seconds)
months(.leap.seconds)
quartes(.leap.seconds)
```

# is the number of days since noon UTC on the first day of 4317 BC.
# in the proleptic Julian calendar. To more recently, in
# 'Terrestrial Time' which differs from UTC by a few seconds
# See https://en.wikipedia.org/wiki/Terrestrial_Time
julian(Sys.Date(), -2440588) # from a day
floor(as.numeric(julian(Sys.time())) + 2440587.5) # from a date-time
which  

Which indices are TRUE?

Description

Give the TRUE indices of a logical object, allowing for array indices.

Usage

which(x, arr.ind = FALSE, useNames = TRUE)
arrayInd(ind, .dim, .dimnames = NULL, useNames = FALSE)

Arguments

x  
a logical vector or array. NAs are allowed and omitted (treated as if FALSE).

arr.ind  
logical; should array indices be returned when x is an array?

ind  
integer-valued index vector, as resulting from which(x).

.dim  
dim(.) integer vector

.dimnames  
optional list of character dimnames(.). If useNames is true, to be used for constructing dimnames for arrayInd() (and hence, which(*, arr.ind=TRUE)). If names(.dimnames) is not empty, these are used as column names. .dimnames[[1]] is used as row names.

useNames  
logical indicating if the value of arrayInd() should have (non-null) dimnames at all.

Value

If arr.ind == FALSE (the default), an integer vector with length equal to sum(x), i.e., to the number of TRUEs in x; Basically, the result is (1:length(x))[x].

If arr.ind == TRUE and x is an array (has a dim attribute), the result is arrayInd(which(x), dim(x), dimnames(x)), namely a matrix whose rows each are the indices of one element of x; see Examples below.

Note

Unlike most other base R functions this does not coerce x to logical: only arguments with typeof logical are accepted and others give an error.

Author(s)

Werner Stahel and Peter Holzer (ETH Zurich) proposed the arr.ind option.

See Also

Logic, which.min for the index of the minimum or maximum, and match for the first index of an element in a vector, i.e., for a scalar a, match(a, x) is equivalent to min(which(x == a)) but much more efficient.
which.min

Where is the Min() or Max() or first TRUE or FALSE?

Examples

which(LETTERS == "R")
which(ll <- c(TRUE, FALSE, TRUE, NA, FALSE, FALSE, TRUE)) #> 1 3 7
names(ll) <- letters[seq(ll)]
which(ll)
which((1:12)%2 == 0) # which are even?
which(1:10 > 3, arr.ind = TRUE)

( m <- matrix(1:12, 3, 4) )
div.3 <- m %% 3 == 0
which(div.3, arr.ind = TRUE)
rownames(m) <- paste("Case", 1:3, sep = "_")
which(m %% 5 == 0, arr.ind = TRUE)

dim(m) <- c(2, 2, 3); m
which(div.3, arr.ind = FALSE)
which(div.3, arr.ind = TRUE)

vm <- c(m)
dim(vm) <- length(vm) #-- funny thing with length(dim(...)) == 1
which(div.3, arr.ind = TRUE)

Description

Determines the location, i.e., index of the (first) minimum or maximum of a numeric (or logical) vector.

Usage

which.min(x)
which.max(x)

Arguments

x numeric (logical, integer or double) vector or an R object for which the internal coercion to double works whose min or max is searched for.

Value

Missing and NaN values are discarded.

an integer or on 64-bit platforms, if length(x) =: n ≥ 2^{31} an integer valued double of length 1 or 0 (iff x has no non-NAs), giving the index of the first minimum or maximum respectively of x.

If this extremum is unique (or empty), the results are the same as (but more efficient than) which(x == min(x, na.rm = TRUE)) or which(x == max(x, na.rm = TRUE)) respectively.
Logical x — First TRUE or FALSE

For a logical vector x with both FALSE and TRUE values, which.min(x) and which.max(x) return the index of the first FALSE or TRUE, respectively, as FALSE < TRUE. However, match(FALSE, x) or match(TRUE, x) are typically preferred, as they do indicate mismatches.

Author(s)
Martin Maechler

See Also
which, max.col, max, etc.

Use arrayInd(), if you need array/matrix indices instead of 1D vector ones.

which.is.max in package nnet differs in breaking ties at random (and having a ‘fuzz’ in the definition of ties).

Examples

```r
x <- c(1:4, 0:5, 11)
which.min(x)
which.max(x)

## it *does* work with NA's present, by discarding them:
presidents[1:30]
range(presidents, na.rm = TRUE)
which.min(presidents) # 28
which.max(presidents) # 2

## Find the first occurrence, i.e. the first TRUE, if there is at least one:
x <- rpois(10000, lambda = 10); x[sample.int(50, 20)] <- NA
## where is the first value >= 20 ?
which.max(x >= 20)

## Also works for lists (which can be coerced to numeric vectors):
which.min(list(A = 7, pi = pi)) ## -> c(pi = 2L)
```

with Evaluate an Expression in a Data Environment

Description

Evaluate an R expression in an environment constructed from data, possibly modifying (a copy of) the original data.

Usage

```r
with(data, expr, ...)
within(data, expr, ...)
```
with

Arguments

- **data**: data to use for constructing an environment. For the default with method this may be an environment, a list, a data frame, or an integer as in sys.call. For within, it can be a list or a data frame.

- **expr**: expression to evaluate.

- **...**: arguments to be passed to future methods.

Details

with is a generic function that evaluates expr in a local environment constructed from data. The environment has the caller’s environment as its parent. This is useful for simplifying calls to modeling functions. (Note: if data is already an environment then this is used with its existing parent.)

Note that assignments within expr take place in the constructed environment and not in the user’s workspace.

within is similar, except that it examines the environment after the evaluation of expr and makes the corresponding modifications to a copy of data (this may fail in the data frame case if objects are created which cannot be stored in a data frame), and returns it. within can be used as an alternative to transform.

Value

For with, the value of the evaluated expr. For within, the modified object.

Note

For interactive use this is very effective and nice to read. For programming however, i.e., in one’s functions, more care is needed, and typically one should refrain from using with(), as, e.g., variables in data may accidentally override local variables, see the reference.

Further, when using modeling or graphics functions with an explicit data argument (and typically using formulas), it is typically preferred to use the data argument of that function rather than to use with(data, ...).

References

evalq, attach, assign, transform.

Examples

```r
with(mtcars, mpg[cyl == 8 & disp > 350])
  # is the same as, but nicer than
mtcars$mpg[mtcars$cyl == 8 & mtcars$disp > 350]
```

```r
require(stats); require(graphics)
```

```r
# examples from glm:
with(data.frame(u = c(5,10,15,20,30,40,60,80,100),
    lot1 = c(118,58,42,35,27,25,21,19,18),
    lot2 = NA),
```

```r
```
lot2 = c(69,35,26,21,18,16,13,12,12)),
list(summary(glm(lot1 ~ log(u), family = Gamma)),
summary(glm(lot2 ~ log(u), family = Gamma))))

aq <- within(airquality, {# Notice that multiple vars can be changed
Ozone <- log(Ozone)
Month <- factor(month.abb[Month])
cTemp <- round((Temp - 32) * 5/9, 1) # From Fahrenheit to Celsius
S.cT <- Solar.R / cTemp # using the newly created variable
rm(Day, Temp)
})
head(aq)

# example from boxplot:
with(ToothGrowth, {
  boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
    subset = (supp == "VC"), col = "yellow",
    main = "Guinea Pigs' Tooth Growth",
    xlab = "Vitamin C dose mg",
    ylab = "tooth length", ylim = c(0, 35))
  boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
    subset = supp == "OJ", col = "orange")
  legend(2, 9, c("Ascorbic acid", "Orange juice"),
    fill = c("yellow", "orange"))
})

# alternate form that avoids subset argument:
with(subset(ToothGrowth, supp == "VC"),
  boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
    col = "yellow", main = "Guinea Pigs' Tooth Growth",
    xlab = "Vitamin C dose mg",
    ylab = "tooth length", ylim = c(0, 35)))
with(subset(ToothGrowth, supp == "OJ"),
  boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
    col = "orange")
legend(2, 9, c("Ascorbic acid", "Orange juice"),
      fill = c("yellow", "orange"))
}

---

**withVisible**  
*Return both a Value and its Visibility*

**Description**

This function evaluates an expression, returning it in a two element list containing its value and a flag showing whether it would automatically print.

**Usage**

`withVisible(x)`

**Arguments**

- `x`  
an expression to be evaluated.
Details

The argument, not an expression object, rather an (unevaluated function) call, is evaluated in the caller's context.
This is a primitive function.

Value

value The value of x after evaluation.
visible logical; whether the value would auto-print.

See Also

invisible, eval; withAutoprint() calls source() which itself uses withVisible() in order to correctly “auto print”.

Examples

x <- 1
withVisible(x <- 1) # $visible is FALSE
x
withVisible(x) # $visible is TRUE

# Wrap the call in evalq() for special handling
df <- data.frame(a = 1:5, b = 1:5)
evalq(withVisible(a + b), envir = df)

write

Write Data to a File

Description

The data (usually a matrix) x are written to file file. If x is a two-dimensional matrix you need to transpose it to get the columns in file the same as those in the internal representation.

Usage

write(x, file = "data",
      ncolumns = if(is.character(x)) 1 else 5,
      append = FALSE, sep = " ")

Arguments

x the data to be written out, usually an atomic vector.
file A connection, or a character string naming the file to write to. If "", print to the standard output connection. If it is "|cmd", the output is piped to the command given by ‘cmd’.
ncolumns the number of columns to write the data in.
append if TRUE the data x are appended to the connection.
sep a string used to separate columns. Using sep = "\t" gives tab delimited output; default is " ".

Usage

write(x, file = "data",
      ncolumns = if(is.character(x)) 1 else 5,
      append = FALSE, sep = " ")
writeLines

Write Lines to a Connection

Description

Write text lines to a connection.

Usage

`writeLines(text, con = stdout(), sep = "\n", useBytes = FALSE)`

Arguments

- **text**: A character vector
- **con**: A connection object or a character string.
- **sep**: character string. A string to be written to the connection after each line of text.
- **useBytes**: logical. See ‘Details’.

Details

If the `con` is a character string, the function calls `file` to obtain a file connection which is opened for the duration of the function call.

If the connection is open it is written from its current position. If it is not open, it is opened for the duration of the call in "wt" mode and then closed again.

Normally `writeLines` is used with a text-mode connection, and the default separator is converted to the normal separator for that platform (LF on Unix/Linux, CRLF on Windows). For more control, open a binary connection and specify the precise value you want written to the file in `sep`. For even more control, use `writeChar` on a binary connection.
useBytes is for expert use. Normally (when false) character strings with marked encodings are converted to the current encoding before being passed to the connection (which might do further re-encoding). useBytes = TRUE suppresses the re-encoding of marked strings so they are passed byte-by-byte to the connection: this can be useful when strings have already been re-encoded by e.g. `iconv`. (It is invoked automatically for strings with marked encoding "bytes".)

**See Also**

`connections, writeChar, writeBin, readLines, cat`

---

### xtfrm

**Auxiliary Function for Sorting and Ranking**

**Description**

A generic auxiliary function that produces a numeric vector which will sort in the same order as `x`.

**Usage**

```r
xtfrm(x)
```

**Arguments**

- `x` an R object.

**Details**

This is a special case of ranking, but as a less general function than `rank` is more suitable to be made generic. The default method is similar to `rank(x, ties.method = "min", na.last = "keep")`, so NA values are given rank NA and all tied values are given equal integer rank.

The `factor` method extracts the codes. The `Surv` method sorts first on times and then on status code(s), finally on `time2` if present. Note that with the conventional status codes this sorts individuals still alive before deaths.

The default method will unclass the object if `is.numeric(x)` is true but otherwise make use of `==` and `>` methods for the class of `x[i]` (for integers i), and the `is.na` method for the class of `x`, but might be rather slow when doing so.

This is an internal generic primitive, so S3 or S4 methods can be written for it.

**Value**

A numeric (usually integer) vector of the same length as `x`.

**See Also**

`rank, sort, order`. 
zapsmall  

**Rounding of Numbers**

**Description**

*zapsmall* determines a digits argument *dr* for calling `round(x, digits = dr)` such that values close to zero (compared with the maximal absolute value) are ‘zapped’, i.e., treated as 0.

**Usage**

```r
zapsmall(x, digits = getOption("digits"))
```

**Arguments**

- **x** a numeric or complex vector.
- **digits** integer indicating the precision to be used.

**References**

**Examples**

```r
x2 <- pi * 100^(-1:3)
print(x2 / 1000, digits = 4)
zapsmall(x2 / 1000, digits = 4)
zapsmall(exp(1i*0:4*pi/2))
```

---

**zpackages**  

**Listing of Packages**

**Description**

*.packages* returns information about package availability.

**Usage**

```r
.packages(all.available = FALSE, lib.loc = NULL)
```

**Arguments**

- **all.available** logical; if TRUE return a character vector of all available packages in `lib.loc`.
- **lib.loc** a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to `.libPaths()`.
Details

.packages() returns the names of the currently attached packages *invisibly* whereas
.packages(all.available = TRUE) gives (visibly) *all* packages available in the library location path lib.loc.

For a package to be regarded as being ‘available’ it must have valid metadata (and hence be an installed package). However, this will report a package as available if the metadata does not match the directory name: use `find.package` to confirm that the metadata match or `installed.packages` for a much slower but more comprehensive check of ‘available’ packages.

Value

A character vector of package base names, invisible unless all.available = TRUE.

Note

.packages(all.available = TRUE) is not a way to find out if a small number of packages are available for use: not only is it expensive when thousands of packages are installed, it is an incomplete test. See the help for `find.package` for why `require` should be used.

Author(s)

R core; Guido Masarotto for the all.available = TRUE part of .packages.

See Also

library, .libPaths, installed.packages.

Examples

```r
.packages()  # maybe just "base"
.packages(all.available = TRUE)  # return all available as character vector
require(splines)
.packages()  # "splines", too
detach("package:splines")
```

---

zutils  

**Miscellaneous Internal/Programming Utilities**

Description

Miscellaneous internal/programming utilities.

Usage

`.standard_regexps()`

Details

`.standard_regexps` returns a list of ‘standard’ regexps, including elements named `valid_package_name` and `valid_package_version` with the obvious meanings. The regexps are not anchored.
Chapter 2

The compiler package

---

### compile Byte Code Compiler

**Description**

These functions provide an interface to a byte code compiler for R.

**Usage**

- `cmpfun(f, options = NULL)`
- `compile(e, env = .GlobalEnv, options = NULL, srcref = NULL)`
- `cmpfile(infile, outfile, ascii = FALSE, env = .GlobalEnv, verbose = FALSE, options = NULL)`
- `loadcmp(file, envir = .GlobalEnv, chdir = FALSE)`
- `disassemble(code)`
- `enableJIT(level)`
- `compilePKGS(enable)`
- `getCompilerOption(name, options)`
- `setCompilerOptions(...)`

**Arguments**

- **f** a closure.
- **options** list of named compiler options: see ‘Details’.
- **env** the top level environment for the compiling.
- **srcref** initial source reference for the expression.
- **file, infile, outfile** pathnames; outfile defaults to infile with a `.Rc` extension in place of any existing extension.
- **ascii** logical; should the compiled file be saved in ascii format?
- **verbose** logical; should the compiler show what is being compiled?
- **envir** environment to evaluate loaded expressions in.
- **chdir** logical; change directory before evaluation?
code  byte code expression or compiled closure

e  expression to compile.

level  integer; the JIT level to use (0 to 3).

enable  logical; enable compiling packages if TRUE.

name  character string; name of option to return.

...  named compiler options to set.

Details

The function cmpfun compiles the body of a closure and returns a new closure with the same formals and the body replaced by the compiled body expression.

compile compiles an expression into a byte code object; the object can then be evaluated with eval.

cmpfile parses the expressions in infile, compiles them, and writes the compiled expressions to outfile. If outfile is not provided, it is formed from infile by replacing or appending a .Rc suffix.

loadcmp is used to load compiled files. It is similar to sys.source, except that its default loading environment is the global environment rather than the base environment.

disassemble produces a printed representation of the code that may be useful to give a hint of what is going on.

enableJIT enables or disables just-in-time (JIT) compilation. JIT is disabled if the argument is 0. If level is 1 then larger closures are compiled before their first use. If level is 2, then some small closures are also compiled before their second use. If level is 3 then in addition all top level loops are compiled before they are executed. JIT level 3 requires the compiler option optimize to be 2 or 3. The JIT level can also be selected by starting R with the environment variable R_ENABLE_JIT set to one of these values. Calling enableJIT with a negative argument returns the current JIT level. The default JIT level is 3.

compilePKGS enables or disables compiling packages when they are installed. This requires that the package uses lazy loading as compilation occurs as functions are written to the lazy loading data base. This can also be enabled by starting R with the environment variable _R_COMPILE_PKGS_ set to a positive integer value. This should not be enabled outside package installation, because it causes any serialized function to be compiled, which comes with time and space overhead. R_COMPILE_PKGS can be used, instead, to instruct INSTALL to enable/disable compilation of packages during installation.

Currently the compiler warns about a variety of things. It does this by using cat to print messages. Eventually this should use the condition handling mechanism.

The options argument can be used to control compiler operation. There are currently three options: optimize, suppressAll, and suppressUndefined. optimize specifies the optimization level, an integer from 0 to 3 (the current out-of-the-box default is 2). suppressAll should be a scalar logical; if TRUE no messages will be shown. suppressUndefined can be TRUE to suppress all messages about undefined variables, or it can be a character vector of the names of variables for which messages should not be shown.

getCompilerOption returns the value of the specified option. The default value is returned unless a value is supplied in the options argument; the options argument is primarily for internal use.

setCompilerOption sets the default option values. Options to set are identified by argument names, e.g. setCompilerOptions(suppressAll = TRUE, optimize = 3). It returns a named list of the previous values.

Calling the compiler a byte code compiler is actually a bit of a misnomer: the external representation of code objects currently uses int operands, and when compiled with gcc the internal representation is actually threaded code rather than byte code.

ability.cov     Ability and Intelligence Tests

Description

Six tests were given to 112 individuals. The covariance matrix is given in this object.

Usage

ability.cov
Details

The tests are described as

general: a non-verbal measure of general intelligence using Cattell’s culture-fair test.
picture: a picture-completion test
blocks: block design
maze: mazes
reading: reading comprehension
cocab: vocabulary

Bartholomew gives both covariance and correlation matrices, but these are inconsistent. Neither are in the original paper.

require(graphics)
plot(airmiles, main = "airmiles data",
     xlab = "Passenger-miles flown by U.S. commercial airlines", col = 4)
```

---

**AirPassengers**

*Monthly Airline Passenger Numbers 1949-1960*

**Description**

The classic Box & Jenkins airline data. Monthly totals of international airline passengers, 1949 to 1960.

**Usage**

AirPassengers

**Format**

A monthly time series, in thousands.

**Source**

**Examples**

```r
## Not run:
## These are quite slow and so not run by example(AirPassengers)
## The classic 'airline model', by full ML
(fit <- arima(log10(AirPassengers), c(0, 1, 1),
             seasonal = list(order = c(0, 1, 1), period = 12)))
update(fit, method = "CSS")
update(fit, x = window(log10(AirPassengers), start = 1954))
pred <- predict(fit, n.ahead = 24)
tl <- pred$pred - 1.96 * pred$se
tu <- pred$pred + 1.96 * pred$se
ts.plot(AirPassengers, 10^tl, 10^tu, log = "y", lty = c(1, 2, 2))

## full ML fit is the same if the series is reversed, CSS fit is not
ap0 <- rev(log10(AirPassengers))
attributes(ap0) <- attributes(AirPassengers)
arima(ap0, c(0, 1, 1), seasonal = list(order = c(0, 1, 1), period = 12))
```
### airquality

#### Description

#### Usage

`airquality`

#### Format

A data frame with 154 observations on 6 variables.

- Ozone: numeric, Ozone (ppb)
- Solar.R: numeric, Solar R (lang)
- Wind: numeric, Wind (mph)
- Temp: numeric, Temperature (degrees F)
- Month: numeric, Month (1–12)
- Day: numeric, Day of month (1–31)

#### Details

Daily readings of the following air quality values for May 1, 1973 (a Tuesday) to September 30, 1973.

- Ozone: Mean ozone in parts per billion from 1300 to 1500 hours at Roosevelt Island
- Solar.R: Solar radiation in Langley's in the frequency band 4000–7700 Angstroms from 0800 to 1200 hours at Central Park
- Wind: Average wind speed in miles per hour at 0700 and 1000 hours at LaGuardia Airport
- Temp: Maximum daily temperature in degrees Fahrenheit at La Guardia Airport.

#### Source

The data were obtained from the New York State Department of Conservation (ozone data) and the National Weather Service (meteorological data).
References

Examples

```r
require(graphics)
pairs(airquality, panel = panel.smooth, main = "airquality data")
```

### Anscombe’s Quartet of ‘Identical’ Simple Linear Regressions

Description

Four \( x-y \) datasets which have the same traditional statistical properties (mean, variance, correlation, regression line, etc.), yet are quite different.

Usage

`anscombe`

Format

A data frame with 11 observations on 8 variables.

- \( x_1 \equiv x_2 \equiv x_3 \) the integers 4:14, specially arranged
- \( x_4 \) values 8 and 19
- \( y_1, y_2, y_3, y_4 \) numbers in (3, 12.5) with mean 7.5 and sdev 2.03

Source

References

Examples

```r
require(stats); require(graphics)
summary(anscombe)
```

```r
##-- now some "magic" to do the 4 regressions in a loop:
ff <- y ~ x
mods <- setNames(as.list(1:4), paste0("lm", 1:4))
for(i in 1:4) {
  ff[2:3] <- lapply(paste0(c("y","x"), i), as.name)
  mods[[i]] <- lm(ff, data = anscombe)
  print(anova(mods[[i]]))
}
```
## See how close they are (numerically!)
sapply(mods, coef)
lapply(mods, function(fm) coef(summary(fm)))

## Now, do what you should have done in the first place: PLOTS
op <- par(mfrow = c(2, 2), mar = 0.1+c(4,4,1,1), oma = c(0, 0, 2, 0))
for(i in 1:4) {
  ff[2:3] <- lapply(paste0(c("y","x"), i), as.name)
  plot(ff, data = anscombe, col = "red", pch = 21, bg = "orange", cex = 1.2,
       xlim = c(3, 19), ylim = c(3, 13))
  abline(mods[[i]], col = "blue")
}
mtext("Anscombe's 4 Regression data sets", outer = TRUE, cex = 1.5)
par(op)

---

### attenu

#### The Joyner–Boore Attenuation Data

#### Description

This data gives peak accelerations measured at various observation stations for 23 earthquakes in California. The data have been used by various workers to estimate the attenuating affect of distance on ground acceleration.

#### Usage

attenu

#### Format

A data frame with 182 observations on 5 variables.

- [.1] event numeric Event Number
- [.2] mag numeric Moment Magnitude
- [.3] station factor Station Number
- [.4] dist numeric Station-hypocenter distance (km)
- [.5] accel numeric Peak acceleration (g)

#### Source

#### References

**Examples**

```r
require(graphics)
## check the data class of the variables
sapply(attenu, data.class)
summary(attenu)
pairs(attenu, main = "attenu data")
coplot(accel ~ dist | as.factor(event), data = attenu, show.given = FALSE)
coplot(log(accel) ~ log(dist) | as.factor(event),
   data = attenu, panel = panel.smooth, show.given = FALSE)
```

**attitude**

*The Chatterjee–Price Attitude Data*

**Description**

From a survey of the clerical employees of a large financial organization, the data are aggregated from the questionnaires of the approximately 35 employees for each of 30 (randomly selected) departments. The numbers give the percent proportion of favourable responses to seven questions in each department.

**Usage**

`attitude`

**Format**

A data frame with 30 observations on 7 variables. The first column are the short names from the reference, the second one the variable names in the data frame:

<p>| | | |</p>
<table>
<thead>

plot(fm2)
par(opar)

austres  Quarterly Time Series of the Number of Australian Residents

Description

Numbers (in thousands) of Australian residents measured quarterly from March 1971 to March 1994. The object is of class "ts".

Usage

austres

Source

beavers  Body Temperature Series of Two Beavers

Description

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver Castor canadensis in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

Usage

beaver1
beaver2

Format

The beaver1 data frame has 114 rows and 4 columns on body temperature measurements at 10 minute intervals.

The beaver2 data frame has 100 rows and 4 columns on body temperature measurements at 10 minute intervals.

The variables are as follows:
day  Day of observation (in days since the beginning of 1990), December 12–13 (beaver1) and November 3–4 (beaver2).

time  Time of observation, in the form 0330 for 3:30am

temp  Measured body temperature in degrees Celsius.

activ  Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing in beaver1.

Source

Examples

```r
require(graphics)
(yl <- range(beaver1$temp, beaver2$temp))

beaver.plot <- function(bdat, ...) {
  nam <- deparse(substitute(bdat))
  with(bdat, {
    # Hours since start of day:
    hours <- time %/% 100 + 24*(day - day[1]) + (time %% 100)/60
    plot(hours, temp, type = "l", ...,
         main = paste(nam, "body temperature"))
    abline(h = 37.5, col = "gray", lty = 2)
    is.act <- activ == 1
    points(hours[is.act], temp[is.act], col = 2, cex = .8)
  })
}

op <- par(mfrow = c(2, 1), mar = c(3, 3, 4, 2), mgp = 0.9 * 2:0)
beaver.plot(beaver1, ylim = yl)
beaver.plot(beaver2, ylim = yl)
par(op)
```

BJsales

Sales Data with Leading Indicator

Description

The sales time series BJsales and leading indicator BJsales.lead each contain 150 observations. The objects are of class "ts".

Usage

BJsales
BJsales.lead
Source

References

Description

The BOD data frame has 6 rows and 2 columns giving the biochemical oxygen demand versus time in an evaluation of water quality.

Usage

BOD

Format

This data frame contains the following columns:

- **Time** A numeric vector giving the time of the measurement (days).
- **demand** A numeric vector giving the biochemical oxygen demand (mg/l).

Source

Examples

```r
require(stats)
# simplest form of fitting a first-order model to these data
fm1 <- nls(demand ~ A*(1-exp(-exp(lrc)*Time)), data = BOD,
    start = c(A = 20, lrc = log(.35)))
coef(fm1)
fm1
# using the plinear algorithm
fm2 <- nls(demand ~ (1-exp(-exp(lrc)*Time)), data = BOD,
    start = c(lrc = log(.35)), algorithm = "plinear", trace = TRUE)
# using a self-starting model
fm3 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
summary(fm3)
```
Description

The data give the speed of cars and the distances taken to stop. Note that the data were recorded in the 1920s.

Usage
cars

Format

A data frame with 50 observations on 2 variables.

anova(cars.1, cars.2, cars.3, cars.4)
```
ChickWeight

Weight versus age of chicks on different diets

Description

The ChickWeight data frame has 578 rows and 4 columns from an experiment on the effect of diet on early growth of chicks.

Usage

ChickWeight

Format

An object of class c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame") containing the following columns:

weight a numeric vector giving the body weight of the chick (gm).
Time a numeric vector giving the number of days since birth when the measurement was made.
Chick an ordered factor with levels 18 < ... < 48 giving a unique identifier for the chick. The ordering of the levels groups chicks on the same diet together and orders them according to their final weight (lightest to heaviest) within diet.
Diet a factor with levels 1, ..., 4 indicating which experimental diet the chick received.

Details

The body weights of the chicks were measured at birth and every second day thereafter until day 20. They were also measured on day 21. There were four groups on chicks on different protein diets.

This dataset was originally part of package nlme, and that has methods (including for \[, as.data.frame, plot and print) for its grouped-data classes.

Source

See Also

SSlogis for models fitted to this dataset.

Examples

```r
require(graphics)
coplot(weight ~ Time | Chick, data = ChickWeight,
       type = "b", show.given = FALSE)
```
**Description**

An experiment was conducted to measure and compare the effectiveness of various feed supplements on the growth rate of chickens.

**Usage**

chickwts

**Format**

A data frame with 71 observations on the following 2 variables.

- **weight**: a numeric variable giving the chick weight.
- **feed**: a factor giving the feed type.

**Details**

Newly hatched chicks were randomly allocated into six groups, and each group was given a different feed supplement. Their weights in grams after six weeks are given along with feed types.

**Source**

**References**

**Examples**

```r
require(stats); require(graphics)
boxplot(weight ~ feed, data = chickwts, col = "lightgray",
varwidth = TRUE, notch = TRUE, main = "chickwt data",
ylab = "Weight at six weeks (gm)")
anova(fm1 <- lm(weight ~ feed, data = chickwts))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0),
mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
par(opar)
```
Carbon Dioxide Uptake in Grass Plants

Description
The CO2 data frame has 84 rows and 5 columns of data from an experiment on the cold tolerance of the grass species Echinochloa crus-galli.

Usage
CO2

Format
An object of class c("nfnGroupedData", "nGroupedData", "groupedData", "data.frame") containing the following columns:

- **Plant**: an ordered factor with levels Qn1 < Qn2 < Qn3 < ... < Mc1 giving a unique identifier for each plant.
- **Type**: a factor with levels Quebec Mississippi giving the origin of the plant
- **Treatment**: a factor with levels nonchilled chilled
- **conc**: a numeric vector of ambient carbon dioxide concentrations (mL/L).
- **uptake**: a numeric vector of carbon dioxide uptake rates (µmol/m² sec).

Details
The CO2 uptake of six plants from Quebec and six plants from Mississippi was measured at several levels of ambient CO2 concentration. Half the plants of each type were chilled overnight before the experiment was conducted.

This dataset was originally part of package nlme, and that has methods (including for [, as.data.frame, plot and print) for its grouped-data classes.

Source

Examples
```
require(stats); require(graphics)
coplot(uptake ~ conc | Plant, data = CO2, show.given = FALSE, type = "b")
## fit the data for the first plant
fm1 <- nls(uptake ~ SSasymp(conc, Asym, lrc, c0),
  data = CO2, subset = Plant == "Qn1")
summary(fm1)
## fit each plant separately
fmlist <- list()
for (pp in levels(CO2$Plant)) {
  fmlist[[pp]] <- nls(uptake ~ SSasymp(conc, Asym, lrc, c0),
```
```r
# check the coefficients by plant
print(sapply(fmlist, coef), digits = 3)
```

---

**co2**  
*Mauna Loa Atmospheric CO2 Concentration*

### Description

Atmospheric concentrations of CO\(_2\) are expressed in parts per million (ppm) and reported in the preliminary 1997 SIO manometric mole fraction scale.

### Usage

```r
c02
```

### Format

A time series of 468 observations; monthly from 1959 to 1997.

### Details

The values for February, March and April of 1964 were missing and have been obtained by interpolating linearly between the values for January and May of 1964.

### Source

     las = 1)
title(main = "co2 data set")
```
Description

Data of 3000 male criminals over 20 years old undergoing their sentences in the chief prisons of England and Wales.

Usage

\texttt{crimtab}

Format

A \texttt{table} object of \texttt{integer} counts, of dimension $42 \times 22$ with a total count, \texttt{sum(crimtab)} of 3000. The 42 \texttt{rownames} ("9.4", "9.5", ...) correspond to midpoints of intervals of finger lengths whereas the 22 column names (\texttt{colnames}) ("142.24", "144.78", ...) correspond to (body) heights of 3000 criminals, see also below.

Details

Student is the pseudonym of William Sealy Gosset. In his 1908 paper he wrote (on page 13) at the beginning of section VI entitled \textit{Practical Test of the forgoing Equations}:

"Before I had succeeded in solving my problem analytically, I had endeavoured to do so empirically. The material used was a correlation table containing the height and left middle finger measurements of 3000 criminals, from a paper by W. R. MacDonell (\textit{Biometrika}, Vol. 1., p. 219). The measurements were written out on 3000 pieces of cardboard, which were then very thoroughly shuffled and drawn at random. As each card was drawn its numbers were written down in a book, which thus contains the measurements of 3000 criminals in a random order. Finally, each consecutive set of 4 was taken as a sample—750 in all—and the mean, standard deviation, and correlation of each sample determined. The difference between the mean of each sample and the mean of the population was then divided by the standard deviation of the sample, giving us the $z$ of Section III."

The table is in fact page 216 and not page 219 in MacDonell(1902). In the MacDonell table, the middle finger lengths were given in mm and the heights in feet/inches intervals, they are both converted into cm here. The midpoints of intervals were used, e.g., where MacDonell has $4^79/16 - 8^9/16$, we have 142.24 which is $2.54 \times 56 = 2.54 \times (4.8')$.

MacDonell credited the source of data (page 178) as follows: \textit{The data on which the memoir is based were obtained, through the kindness of Dr Garson, from the Central Metric Office, New Scotland Yard...} He pointed out on page 179 that: \textit{The forms were drawn at random from the mass on the office shelves; we are therefore dealing with a random sampling.}

References

Examples

```r
require(stats)
dim(crimtab)
utils::str(crimtab)
## for nicer printing:
local({cT <- crimtab
colnames(cT) <- substring(colnames(cT), 2, 3)
print(cT, zero.print = " ")})
## Repeat Student's experiment:
# 1) Reconstitute 3000 raw data for heights in inches and rounded to
# nearest integer as in Student's paper:
(heIn <- round(as.numeric(colnames(crimtab)) / 2.54))
d.hei <- data.frame(height = rep(heIn, colSums(crimtab)))
# 2) shuffle the data:
set.seed(1)
d.hei <- d.hei[sample(1:3000), , drop = FALSE]
# 3) Make 750 samples each of size 4:
d.hei$sample <- as.factor(rep(1:750, each = 4))
# 4) Compute the means and standard deviations (n) for the 750 samples:
h.mean <- with(d.hei, tapply(height, sample, FUN = mean))
h.sd <- with(d.hei, tapply(height, sample, FUN = sd)) * sqrt(3/4)
# 5) Compute the difference between the mean of each sample and
# the mean of the population and then divide by the
# standard deviation of the sample:
zobs <- (h.mean - mean(d.hei[,"height"]))/h.sd
# 6) Replace infinite values by +/- 6 as in Student's paper:
zobs[is.infinite(zobs)] <- 6 * sign(zobs[is.infinite(zobs)])
# 7) Plot the distribution:
require(grDevices); require(graphics)
hist(x = zobs, probability = TRUE, xlab = "Student's z",
```
discoveries  

Yearly Numbers of Important Discoveries

Description
The numbers of "great" inventions and scientific discoveries in each year from 1860 to 1959.

Usage
discoveries

Format
A time series of 100 values.

Source

References

Examples
```r

DNase  

Elisa assay of DNase

Description
The DNase data frame has 176 rows and 3 columns of data obtained during development of an ELISA assay for the recombinant protein DNase in rat serum.

Usage
DNase
esoph

Description

Data from a case-control study of (o)esophageal cancer in Ille-et-Vilaine, France.

Usage

esoph

Format

A data frame with records for 88 age/alcohol/tobacco combinations.

Format

An object of class c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame") containing the following columns:

Run an ordered factor with levels 10 < ... < 3 indicating the assay run.
conc a numeric vector giving the known concentration of the protein.
density a numeric vector giving the measured optical density (dimensionless) in the assay. Duplicate optical density measurements were obtained.

Details

This dataset was originally part of package nlme, and that has methods (including for [, as.data.frame, plot and print) for its grouped-data classes.

Source

Examples

euro

Conversion Rates of Euro Currencies

Description

Conversion rates between the various Euro currencies.

Usage

euro
euro.cross

Format

euro is a named vector of length 11, euro.cross a matrix of size 11 by 11, with dimnames.

Details

The data set euro contains the value of 1 Euro in all currencies participating in the European monetary union (Austrian Schilling ATS, Belgian Franc BEF, German Mark DEM, Spanish Peseta ESP, Finnish Markka FIM, French Franc FRF, Irish Punt IEP, Italian Lira ITL, Luxembourg Franc LUF, Dutch Guilder NLG and Portuguese Escudo PTE). These conversion rates were fixed by the European Union on December 31, 1998. To convert old prices to Euro prices, divide by the respective rate and round to 2 digits.

The data set euro.cross contains conversion rates between the various Euro currencies, i.e., the result of outer(1 / euro, euro).

Examples

cbind(euro)

## These relations hold:
euro == signif(euro, 6) # [6 digit precision in Euro's definition]
all(euro.cross == outer(1/euro, euro))

## Convert 20 Euro to Belgian Franc
20 * euro["BEF"]

## Convert 20 Austrian Schilling to Euro
20 / euro["ATS"]

## Convert 20 Spanish Pesetas to Italian Lira
20 * euro.cross["ESP", "ITL"]

require(graphics)
dotchart(euro,
    main = "euro data: 1 Euro in currency unit")
dotchart(1/euro,
    main = "euro data: 1 currency unit in Euros")
dotchart(log(euro, 10),
    main = "euro data: log10(1 Euro in currency unit)")
EuStockMarkets

---

eurodist

*Distances Between European Cities and Between US Cities*

**Description**

The eurodist gives the road distances (in km) between 21 cities in Europe. The data are taken from a table in *The Cambridge Encyclopaedia.*

UScitiesD gives “straight line” distances between 10 cities in the US.

**Usage**

```r
eurodist
UScitiesD
```

**Format**

dist objects based on 21 and 10 objects, respectively. (You must have the stats package loaded to have the methods for this kind of object available).

**Source**

The US cities distances were provided by Pierre Legendre.

---

EuStockMarkets

*Daily Closing Prices of Major European Stock Indices, 1991–1998*

**Description**

Contains the daily closing prices of major European stock indices: Germany DAX (Ibis), Switzerland SMI, France CAC, and UK FTSE. The data are sampled in business time, i.e., weekends and holidays are omitted.

**Usage**

```r
EuStockMarkets
```

**Format**

A multivariate time series with 1860 observations on 4 variables. The object is of class "mts".

**Source**

The data were kindly provided by Erste Bank AG, Vienna, Austria.
**faithful**

**Old Faithful Geyser Data**

**Description**
Waiting time between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.

**Usage**

`faithful`

**Format**

A data frame with 272 observations on 2 variables.

```
[,1] eruptions numeric Eruption time in mins
[,2] waiting numeric Waiting time to next eruption (in mins)
```

**Details**

A closer look at `faithful$eruptions` reveals that these are heavily rounded times originally in seconds, where multiples of 5 are more frequent than expected under non-human measurement. For a better version of the eruption times, see the example below.

There are many versions of this dataset around: Azzalini and Bowman (1990) use a more complete version.

**Source**

W. Härdle.

**References**

**See Also**

`geyser` in package **MASS** for the Azzalini–Bowman version.

**Examples**

```r
require(stats); require(graphics)
f.tit <- "faithful data: Eruptions of Old Faithful"

ne60 <- round(e60 <- 60 * faithful$eruptions)
all.equal(e60, ne60) # relative diff. ~ 1/10000
table(zapsmall(abs(e60 - ne60))) # 0, 0.02 or 0.04
faithful$better.eruptions <- ne60 / 60
te <- table(ne60)
```
te[te >= 4]  # (too) many multiples of 5 !
plot(names(te), te, type = "h", main = f.tit, xlab = "Eruption time (sec")

plot(faithful[, -3], main = f.tit,
     xlab = "Eruption time (min)",
     ylab = "Waiting time to next eruption (min")
lines(lowess(faithful$eruptions, faithful$waiting, f = 2/3, iter = 3),
     col = "red")

Formaldehyde  

Determination of Formaldehyde

Description

These data are from a chemical experiment to prepare a standard curve for the determination of formaldehyde by the addition of chromatropic acid and concentrated sulphuric acid and the reading of the resulting purple color on a spectrophotometer.

Usage

Formaldehyde

Format

A data frame with 6 observations on 2 variables.

[,1]  carb  numeric  Carbohydrate (ml)
[,2]  optden  numeric  Optical Density

Source

References

Examples

require(stats); require(graphics)
plot(optden ~ carb, data = Formaldehyde,
     xlab = "Carbohydrate (ml)", ylab = "Optical Density",
     main = "Formaldehyde data", col = 4, las = 1)

plot(fm1)
par(par)
Description

Freeny’s data on quarterly revenue and explanatory variables.

Usage

freeny
freeny.x
freeny.y

Format

There are three ‘freeny’ data sets.
freeny.y is a time series with 39 observations on quarterly revenue from (1962,2Q) to (1971,4Q).
freeny.x is a matrix of explanatory variables. The columns are freeny.y lagged 1 quarter, price index, income level, and market potential.
Finally, freeny is a data frame with variables y, lag.quarterly.revenue, price.index, income.level, and market.potential obtained from the above two data objects.

Source

References

Examples

require(stats); require(graphics)
summary(freeny)
pairs(freeny, main = "freeny data")
# gives warning: freeny$y has class "ts"

summary(fm1 <- lm(y ~ ., data = freeny))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0),
mar = c(4.1, 4.1, 2.1, 1.1))
plot(fm1)
par(opar)
HairEyeColor

Hair and Eye Color of Statistics Students

Description

Distribution of hair and eye color and sex in 592 statistics students.

Usage

HairEyeColor

Format

A 3-dimensional array resulting from cross-tabulating 592 observations on 3 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Hair</td>
<td>Black, Brown, Red, Blond</td>
</tr>
<tr>
<td>2</td>
<td>Eye</td>
<td>Brown, Blue, Hazel, Green</td>
</tr>
<tr>
<td>3</td>
<td>Sex</td>
<td>Male, Female</td>
</tr>
</tbody>
</table>

Details

The Hair × Eye table comes from a survey of students at the University of Delaware reported by Snee (1974). The split by Sex was added by Friendly (1992a) for didactic purposes.

This data set is useful for illustrating various techniques for the analysis of contingency tables, such as the standard chi-squared test or, more generally, log-linear modelling, and graphical methods such as mosaic plots, sieve diagrams or association plots.

Source

http://euclid.psych.yorku.ca/ftp/sas/vcd/catdata/haireye.sas

Snee (1974) gives the two-way table aggregated over Sex. The Sex split of the ‘Brown hair, Brown eye’ cell was changed to agree with that used by Friendly (2000).

**Pharmacokinetics of Indomethacin**

### Description

The Indometh data frame has 66 rows and 3 columns of data on the pharmacokinetics of indometacin (or, older spelling, ‘indomethacin’).

### Usage

Indometh

### Format

An object of class c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame") containing the following columns:

- **Subject**: an ordered factor with containing the subject codes. The ordering is according to increasing maximum response.
- **time**: a numeric vector of times at which blood samples were drawn (hr).
- **conc**: a numeric vector of plasma concentrations of indometacin (mcg/ml).

### Details

Each of the six subjects were given an intravenous injection of indometacin.

This dataset was originally part of package nlme, and that has methods (including for [, as.data.frame, plot and print) for its grouped-data classes.

### Source

**iris**

*Edgar Anderson’s Iris Data*
Description

This famous (Fisher’s or Anderson’s) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.

Usage

iris
iris3

Format

iris is a data frame with 150 cases (rows) and 5 variables (columns) named Sepal.Length, Sepal.Width, Petal.Length, Petal.Width, and Species.

iris3 gives the same data arranged as a 3-dimensional array of size 50 by 4 by 3, as represented by S-PLUS. The first dimension gives the case number within the species subsample, the second the measurements with names Sepal L., Sepal W., Petal L., and Petal W., and the third the species.

Source

References

See Also

matplot some examples of which use iris.

Examples

dni3 <- dimnames(iris3)

monthplot(fit)
```

LakeHuron

**Level of Lake Huron 1875–1972**

**Description**

Annual measurements of the level, in feet, of Lake Huron 1875–1972.

**Usage**

`LakeHuron`

**Format**

A time series of length 98.

**Source**

Luteinizing Hormone in Blood Samples

**Description**

A regular time series giving the luteinizing hormone in blood samples at 10 mins intervals from a human female, 48 samples.

**Usage**

`lh`

**Source**

LifeCycleSavings  

Description

Usage

LifeCycleSavings

Format

A data frame with 50 observations on 5 variables.

[1] sr    numeric  aggregate personal savings
[2] pop15 numeric  % of population under 15
[3] pop75 numeric  % of population over 75
[4] dpi   numeric  real per-capita disposable income
[5] ddpi  numeric  % growth rate of dpi

Details

Under the life-cycle savings hypothesis as developed by Franco Modigliani, the savings ratio (aggregate personal saving divided by disposable income) is explained by per-capita disposable income, the percentage rate of change in per-capita disposable income, and two demographic variables: the percentage of population less than 15 years old and the percentage of the population over 75 years old. The data are averaged over the decade 1960–1970 to remove the business cycle or other short-term fluctuations.

Source

The data were obtained from Belsley, Kuh and Welsch (1980). They in turn obtained the data from Sterling (1977).

References

Examples

```
require(stats); require(graphics)
pairs(LifeCycleSavings, panel = panel.smooth,
main = "LifeCycleSavings data")
fm1 <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
summary(fm1)
```
Loblolly

**Description**

The Loblolly data frame has 84 rows and 3 columns of records of the growth of Loblolly pine trees.

**Usage**

Loblolly

**Format**

An object of class `c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame")` containing the following columns:

- **height** a numeric vector of tree heights (ft).
- **age** a numeric vector of tree ages (yr).
- **Seed** an ordered factor indicating the seed source for the tree. The ordering is according to increasing maximum height.

**Details**

This dataset was originally part of package nlme, and that has methods (including for `[`, `as.data.frame`, `plot` and `print`) for its grouped-data classes.

**Source**

**Examples**

```r
require(stats); require(graphics)
plot(height ~ age, data = Loblolly, subset = Seed == 329,
     xlab = "Tree age (yr)", las = 1,
     ylab = "Tree height (ft)",
     main = "Loblolly data and fitted curve (Seed 329 only)"
)
fml <- nls(height ~ SSasymp(age, Asym, R0, lrc),
           data = Loblolly, subset = Seed == 329)
age <- seq(0, 30, length.out = 101)
lines(age, predict(fml, list(age = age)))
```
longley

*Longley's Economic Regression Data*

**Description**

A macroeconomic data set which provides a well-known example for a highly collinear regression.

**Usage**

longley

**Format**

A data frame with 7 economical variables, observed yearly from 1947 to 1962 ($n = 16$).

- **GNP.deflator**  GNP implicit price deflator (1954 = 100)
- **GNP**  Gross National Product.
- **Unemployed**  number of unemployed.
- **Armed.Forces**  number of people in the armed forces.
- **Population**  ‘noninstitutionalized’ population $\geq 14$ years of age.
- **Year**  the year (time).
- **Employed**  number of people employed.

The regression `lm(Employed ~ .)` is known to be highly collinear.

**Source**

**References**

**Examples**

```r
require(stats); require(graphics)
## give the data set in the form it is used in S-PLUS:
longley.x <- data.matrix(longley[, 1:6])
longley.y <- longley[, "Employed"]
pairs(longley, main = "longley data")
summary(fm1 <- lm(Employed ~ ., data = longley))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0),

### lynx

**Description**

Annual numbers of lynx trappings for 1821–1934 in Canada. Taken from Brockwell & Davis (1991), this appears to be the series considered by Campbell & Walker (1977).

**Usage**

1lynx

**Source**

**References**

### morley

**Description**

A classical data of Michelson (but not this one with Morley) on measurements done in 1879 on the speed of light. The data consists of five experiments, each consisting of 20 consecutive ‘runs’. The response is the speed of light measurement, suitably coded (km/sec, with 299000 subtracted).

**Usage**

morley

**Format**

A data frame with 100 observations on the following 3 variables.

- **Expt**  The experiment number, from 1 to 5.
- **Run**   The run number within each experiment.
- **Speed** Speed-of-light measurement.

**Details**

The data is here viewed as a randomized block experiment with ‘experiment’ and ‘run’ as the factors. ‘run’ may also be considered a quantitative variate to account for linear (or polynomial) changes in the measurement over the course of a single experiment.
Note

This is the same dataset as michelson in package MASS.

Source

A. A. Michelson (1882) Experimental determination of the velocity of light made at the United States Naval Academy, Annapolis. Astronomic Papers 1 135–8. U.S. Nautical Almanac Office. (See Table 24.)

Examples

require(stats); require(graphics)
michelson <- transform(morley,

```

<table>
<thead>
<tr>
<th>nhtemp</th>
<th>Average Yearly Temperatures in New Haven</th>
</tr>
</thead>
</table>

Description

The mean annual temperature in degrees Fahrenheit in New Haven, Connecticut, from 1912 to 1971.

Usage

nhtemp

Format

A time series of 60 observations.

Source

References

Examples

```r
require(stats); require(graphics)
plot(nhtemp, main = "nhtemp data",
     ylab = "Mean annual temperature in New Haven, CT (deg. F)")
```
Flow of the River Nile

Description

Measurements of the annual flow of the river Nile at Aswan (formerly Assuan), 1871–1970, in $10^8 m^3$, "with apparent changepoint near 1898" (Cobb(1978), Table 1, p.249).

Usage

Nile

Format

A time series of length 100.

**nottem**

**Average Monthly Temperatures at Nottingham, 1920–1939**

**Description**

A time series object containing average air temperatures at Nottingham Castle in degrees Fahrenheit for 20 years.

**Usage**

`nottem`

**Source**

**Examples**

```r
require(stats); require(graphics)
nott <- window(nottem, end = c(1936,12))
fit <- arima(nott, order = c(1,0,0), list(order = c(2,1,0), period = 12))
nott.fore <- predict(fit, n.ahead = 36)
tst.plot(nott, nott.fore$pred, nott.fore$pred+2*nott.fore$se,
        nott.fore$pred-2*nott.fore$se, gpars = list(col = c(1,1,4,4)))
```
Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

npk

Format

The npk data frame has 24 rows and 5 columns:

- block which block (label 1 to 6).
- N indicator (0/1) for the application of nitrogen.
- P indicator (0/1) for the application of phosphate.
- K indicator (0/1) for the application of potassium.
- yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

Source

References

Examples

```r
options(contrasts = c("contr.sum", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
npk.aov
summary(npk.aov)
coef(npk.aov)
options(contrasts = c("contr.treatment", "contr.poly"))
npk.aov1 <- aov(yield ~ block + N + K, data = npk)
summary.lm(npk.aov1)
se.contrast(npk.aov1, list(N=="0", N=="1"), data = npk)
model.tables(npk.aov1, type = "means", se = TRUE)
```
occupationalStatus

**Description**

Cross-classification of a sample of British males according to each subject’s occupational status and his father’s occupational status.

**Usage**

`occupationalStatus`

**Format**

A table of counts, with classifying factors `origin` (father’s occupational status; levels 1:8) and `destination` (son’s occupational status; levels 1:8).

**Source**

The data set has been in package `gnm` and been provided by the package authors.

**Examples**

```r
require(stats); require(graphics)

plot(occupationalStatus)

## Fit a uniform association model separating diagonal effects
Diag <- as.factor(diag(1:8))
Rscore <- scale(as.numeric(row(occupationalStatus)), scale = FALSE)
Cscore <- scale(as.numeric(col(occupationalStatus)), scale = FALSE)
modUnif <- glm(Freq ~ origin + destination + Diag + Rscore:Cscore,
               family = poisson, data = occupationalStatus)

summary(modUnif)
plot(modUnif) # 4 plots, with warning about h_ii ~= 1
```

---

Orange

**Description**

The Orange data frame has 35 rows and 3 columns of records of the growth of orange trees.

**Usage**

`Orange`
**OrchardSprays**

**Potency of Orchard Sprays**

**Description**

An experiment was conducted to assess the potency of various constituents of orchard sprays in repelling honeybees, using a Latin square design.

**Usage**

OrchardSprays

**Format**

A data frame with 64 observations on 4 variables.

<table>

</tr>
</tbody>
</table>

**Details**

This dataset was originally part of package `nlme`, and that has methods (including for `[`, `as.data.frame`, `plot` and `print`) for its grouped-data classes.

**Source**

**Examples**

```r
require(stats); require(graphics)
coplot(circumference ~ age | Tree, data = Orange, show.given = FALSE)
fml <- nls(circumference ~ SSlogis(age, Asym, xmid, scal), data = Orange, subset = Tree == 3)
plot(circumference ~ age, data = Orange, subset = Tree == 3, 
     xlab = "Tree age (days since 1968/12/31)", 
ylab = "Tree circumference (mm)", las = 1, 
     main = "Orange tree data and fitted model (Tree 3 only)")
age <- seq(0, 1600, length.out = 101)
lines(age, predict(fml, list(age = age)))
```
Details

Individual cells of dry comb were filled with measured amounts of lime sulphur emulsion in sucrose solution. Seven different concentrations of lime sulphur ranging from a concentration of 1/100 to 1/1,562,500 in successive factors of 1/5 were used as well as a solution containing no lime sulphur. The responses for the different solutions were obtained by releasing 100 bees into the chamber for two hours, and then measuring the decrease in volume of the solutions in the various cells.

An $8 \times 8$ Latin square design was used and the treatments were coded as follows:

- **A**: highest level of lime sulphur
- **B**: next highest level of lime sulphur
- ...
- **G**: lowest level of lime sulphur
- **H**: no lime sulphur

Source

References

Examples

```r
require(graphics)
pairs(OrchardSprays, main = "OrchardSprays data")
```

---

**PlantGrowth**

Results from an Experiment on Plant Growth

Description

Results from an experiment to compare yields (as measured by dried weight of plants) obtained under a control and two different treatment conditions.

Usage

`PlantGrowth`

Format

A data frame of 30 cases on 2 variables.

```
[, 1] weight  numeric
[, 2] group   factor
```

The levels of `group` are ‘ctrl’, ‘trt1’, and ‘trt2’.
precip

Source

Examples

### One factor ANOVA example from Dobson's book, cf. Table 7.4:

```r
require(stats); require(graphics)
boxplot(weight ~ group, data = PlantGrowth, main = "PlantGrowth data",
ylab = "Dried weight of plants", col = "lightgray",
notch = TRUE, varwidth = TRUE)
anova(lm(weight ~ group, data = PlantGrowth))
```

Description

The average amount of precipitation (rainfall) in inches for each of 70 United States (and Puerto Rico) cities.

Usage

precip

Format

A named vector of length 70.

Note

The dataset version up to Nov.16, 2016 had a typo in "Cincinnati"'s name. The examples show how to recreate that version.

Source

References

Examples

```r
require(graphics)
dotchart(precip[order(precip)], main = "precip data")
title(sub = "Average annual precipitation (in.)")

### Old ("wrong") version of dataset (just name change):

```r
cprecip.0 <- local(
  p <- precip; names(p)[names(p) == "Cincinnati"] <- "Cincinati" ; p )
stopifnot(all(precip == precip.0),
  match("Cincinnati", names(precip)) == 46,
  identical(names(precip)[-46], names(precip.0)[-46]))
```
presidents

Quarterly Approval Ratings of US Presidents

Description

The (approximately) quarterly approval rating for the President of the United States from the first quarter of 1945 to the last quarter of 1974.

Usage

presidents

Format

A time series of 120 values.

Details

The data are actually a fudged version of the approval ratings. See McNeil’s book for details.

Source

The Gallup Organisation.

References

Examples

```r
require(stats); require(graphics)
plot(presidents, las = 1, ylab = "Approval rating (%)",
     main = "presidents data")
```

pressure

Vapor Pressure of Mercury as a Function of Temperature

Description

Data on the relation between temperature in degrees Celsius and vapor pressure of mercury in millimeters (of mercury).

Usage

pressure

Format

A data frame with 19 observations on 2 variables.

<table>
<thead>
<tr>
<th></th>
<th>temperature</th>
<th>pressure</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

Source

References

Examples

```r
require(graphics)
plot(pressure, xlab = "Temperature (deg C)",
     ylab = "Pressure (mm of Hg)",
     main = "pressure data: Vapor Pressure of Mercury")
plot(pressure, xlab = "Temperature (deg C)", log = "y",
     ylab = "Pressure (mm of Hg)",
     main = "pressure data: Vapor Pressure of Mercury")
```

Puromycin  Reaction Velocity of an Enzymatic Reaction

Description

The *Puromycin* data frame has 23 rows and 3 columns of the reaction velocity versus substrate concentration in an enzymatic reaction involving untreated cells or cells treated with Puromycin.

Usage

Puromycin

Format

This data frame contains the following columns:

- **conc** a numeric vector of substrate concentrations (ppm)
- **rate** a numeric vector of instantaneous reaction rates (counts/min/min)
- **state** a factor with levels treated untreated

Details

Data on the velocity of an enzymatic reaction were obtained by Treloar (1974). The number of counts per minute of radioactive product from the reaction was measured as a function of substrate concentration in parts per million (ppm) and from these counts the initial rate (or velocity) of the reaction was calculated (counts/min/min). The experiment was conducted once with the enzyme treated with Puromycin, and once with the enzyme untreated.

Source

See Also

SSmicmen for other models fitted to this dataset.

Examples

```r
require(stats); require(graphics)

plot(rate ~ conc, data = Puromycin, las = 1,
     xlab = "Substrate concentration (ppm)",
     ylab = "Reaction velocity (counts/min/min)",
     pch = as.integer(Puromycin$state),
     col = as.integer(Puromycin$state),
     main = "Puromycin data and fitted Michaelis-Menten curves")

## simplest form of fitting the Michaelis-Menten model to these data
fm1 <- nls(rate ~ Vm * conc/(K + conc), data = Puromycin,
            subset = state == "treated",
            start = c(Vm = 200, K = 0.05))
fm2 <- nls(rate ~ Vm * conc/(K + conc), data = Puromycin,
            subset = state == "untreated",
            start = c(Vm = 160, K = 0.05))
summary(fm1)
summary(fm2)
## add fitted lines to the plot
conc <- seq(0, 1.2, length.out = 101)
lines(conc, predict(fm1, list(conc = conc)), lty = 1, col = 1)
lines(conc, predict(fm2, list(conc = conc)), lty = 2, col = 2)
legend(0.8, 120, levels(Puromycin$state),
       col = 1:2, lty = 1:2, pch = 1:2)

## using partial linearity
fm3 <- nls(rate ~ conc/(K + conc), data = Puromycin,
            subset = state == "treated", start = c(K = 0.05),
            algorithm = "plinear")
```

### quakes

**Locations of Earthquakes off Fiji**

**Description**

The data set give the locations of 1000 seismic events of MB > 4.0. The events occurred in a cube near Fiji since 1964.

**Usage**

quakes

**Format**

A data frame with 1000 observations on 5 variables.

- **[,1] lat** numeric Latitude of event
- **[,2] long** numeric Longitude
- **[,3] depth** numeric Depth (km)
- **[,4] mag** numeric Richter Magnitude
- **[,5] stations** numeric Number of stations reporting
Details

There are two clear planes of seismic activity. One is a major plate junction; the other is the Tonga trench off New Zealand. These data constitute a subsample from a larger dataset of containing 5000 observations.

Source

This is one of the Harvard PRIM-H project data sets. They in turn obtained it from Dr. John Woodhouse, Dept. of Geophysics, Harvard University.

Examples

```r
require(graphics)
pairs(quakes, main = "Fiji Earthquakes, N = 1000", cex.main = 1.2, pch = ".")
```

---

**randu**

*Random Numbers from Congruential Generator RANDU*

Description

400 triples of successive random numbers were taken from the VAX FORTRAN function RANDU running under VMS 1.5.

Usage

`randu`

Format

A data frame with 400 observations on 3 variables named `x`, `y` and `z` which give the first, second and third random number in the triple.

Details

In three dimensional displays it is evident that the triples fall on 15 parallel planes in 3-space. This can be shown theoretically to be true for all triples from the RANDU generator.

These particular 400 triples start 5 apart in the sequence, that is they are \((\text{U}[5i+1], \text{U}[5i+2], \text{U}[5i+3]), i = 0, \ldots, 399\), and they are rounded to 6 decimal places.

Under VMS versions 2.0 and higher, this problem has been fixed.

Source

David Donoho
rivers

Description

This data set gives the lengths (in miles) of 141 “major” rivers in North America, as compiled by the US Geological Survey.

Usage

rivers

Format

A vector containing 141 observations.

Source

References

rock

Description

Measurements on 48 rock samples from a petroleum reservoir.

Usage

rock

Format

A data frame with 48 rows and 4 numeric columns.
| .1| area | area of pores space, in pixels out of 256 by 256 |
| .2| peri | perimeter in pixels |
| .3| shape | perimeter/sqrt(area) |
| .4| perm | permeability in milli-Darcies |

Details

Twelve core samples from petroleum reservoirs were sampled by 4 cross-sections. Each core sample was measured for permeability, and each cross-section has total area of pores, total perimeter of pores, and shape.

Source

Data from BP Research, image analysis by Ronit Katz, U. Oxford.

---

### sleep

#### Student’s Sleep Data

<table>
<thead>
<tr>
<th>extra</th>
<th>numeric increase in hours of sleep</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>drug given</td>
</tr>
<tr>
<td>ID</td>
<td>patient ID</td>
</tr>
</tbody>
</table>

Details

The group variable name may be misleading about the data: They represent measurements on 10 persons, not in groups.

Source

References

Examples

```r
require(stats)
## Student's paired t-test
with(sleep, 
t.test(extra[group == 1],
    extra[group == 2], paired = TRUE))

## The sleep prolongations
sleep1 <- with(sleep, extra[group == 2] - extra[group == 1])
summary(sleep1)
stripchart(sleep1, method = "stack", xlab = "hours",
    main = "Sleep prolongation (n = 10)"
    boxplot(sleep1, horizontal = TRUE, add = TRUE,
        at = .6, pars = list(boxwex = 0.5, staplewex = 0.25))
```
dependent variable) is 10 times the percentage of the ingoing ammonia to the plant that escapes from the absorption column unabsorbed; that is, an (inverse) measure of the over-all efficiency of the plant.

Source

References

Examples

```r
require(stats)
summary(lm(stack <- lm(stack.loss ~ stack.x))
```

---

**state**

**US State Facts and Figures**

**Description**

Data sets related to the 50 states of the United States of America.

**Usage**

- `state.abb`
- `state.area`
- `state.center`
- `state.division`
- `state.name`
- `state.region`
- `state.x77`

**Details**

R currently contains the following “state” data sets. Note that all data are arranged according to alphabetical order of the state names.

- `state.abb`: character vector of 2-letter abbreviations for the state names.
- `state.area`: numeric vector of state areas (in square miles).
- `state.center`: list with components named `x` and `y` giving the approximate geographic center of each state in negative longitude and latitude. Alaska and Hawaii are placed just off the West Coast.
- `state.division`: factor giving state divisions (New England, Middle Atlantic, South Atlantic, East South Central, West South Central, East North Central, West North Central, Mountain, and Pacific).
sunspot.month

state.name: character vector giving the full state names.
state.region: factor giving the region (Northeast, South, North Central, West) that each state belongs to.
state.x77: matrix with 50 rows and 8 columns giving the following statistics in the respective columns.
  Population: population estimate as of July 1, 1975
  Income: per capita income (1974)
  Illiteracy: illiteracy (1970, percent of population)
  Life Exp: life expectancy in years (1969–71)
  Murder: murder and non-negligent manslaughter rate per 100,000 population (1976)
  HS Grad: percent high-school graduates (1970)
  Frost: mean number of days with minimum temperature below freezing (1931–1960) in capital or large city
  Area: land area in square miles

Source

References

sunspot.month  Monthly Sunspot Data, from 1749 to "Present"

Description

Monthly numbers of sunspots, as from the World Data Center, aka SIDC. This is the version of the data that will occasionally be updated when new counts become available.

Usage

sunspot.month

Format

The univariate time series sunspot.year and sunspot.month contain 289 and 2988 observations, respectively. The objects are of class "ts".

Author(s)

R

Source

WDC-SILSO, Solar Influences Data Analysis Center (SIDC), Royal Observatory of Belgium, Av. Circulaire, 3, B-1180 BRUSSELS Currently at http://www.sidc.be/silso/datafiles
See Also

sunspot.month is a longer version of sunspots: the latter runs until 1983 and is kept fixed (for reproducibility as example dataset).

Examples

require(stats); require(graphics)
## Compare the monthly series
plot(sunspot.month,
     main="sunspot.month & sunspots [package\'datasets\']", col=2)
lines(sunspots) # -> faint differences where they overlap

## Now look at the difference :
all(tsp(sunspots)[c(1,3)] ==
    tsp(sunspot.month)[c(1,3)]) # Start & Periodicity are the same
n1 <- length(sunspots)
table(eq <- sunspots == sunspot.month[1:n1]) #> 132 are different!
i <- which(!eq)
rug(time(eq)[i])
s1 <- sunspots[i] ; s2 <- sunspot.month[i]
cbind(i = i, time = time(sunspots)[i], sunspots = s1, ss.month = s2,
      perc.diff = round(100*2*abs(s1-s2)/(s1+s2), 1))

## How to recreate the "old" sunspot.month (R <= 3.0.3):
.sunspot.diff <- cbind(
i = c(1202L, 1256L, 1258L, 1301L, 1407L, 1429L, 1452L, 1455L,
     1663L, 2151L, 2329L, 2498L, 2594L, 2694L, 2819L),
    res10 = c(1L, 1L, 1L, -1L, -1L, -1L, 1L, -1L,
             1L, 1L, 1L, 1L, 1L, 20L, 1L))
ssm0 <- sunspot.month[1:2988]
with(as.data.frame(.sunspot.diff), ssm0[i] <<- ssm0[i] - res10/10)
sunspot.month.0 <- ts(ssm0, start = 1749, frequency = 12)

sunspot.year

Yearly Sunspot Data, 1700–1988

Description

Yearly numbers of sunspots from 1700 to 1988 (rounded to one digit).

Note that monthly numbers are available as sunspot.month, though starting slightly later.

Usage

sunspot.year

Format

The univariate time series sunspot.year contains 289 observations, and is of class "ts".

Source

See Also

For monthly sunspot numbers, see `sunspot.month` and `sunspots`.

Regularly updated yearly sunspot numbers are available from WDC-SILSO, Royal Observatory of Belgium, at http://www.sidc.be/silso/datafiles

Examples

```r
utils::str(sm <- sunspots)# the monthly version we keep unchanged
utils::str(sy <- sunspot.year)
## The common time interval
(t1 <- c(max(start(sm), start(sy)), 1)) # Jan 1749
(t2 <- c(min( end(sm)[1],end(sy)[1]), 12)) # Dec 1983
s.m <- window(sm, start=t1, end=t2)
s.y <- window(sy, start=t1, end=t2[1]) # (irrelevant warning)
stopifnot(length(s.y) * 12 == length(s.m),
      ## The yearly series *is* close to the averages of the monthly one: all.equal(s.y, aggregate(s.m, FUN = mean), tol = 0.0020))
## NOTE: Strangely, correctly weighting the number of days per month
## (using 28.25 for February) is *not* closer than the simple mean:
ndays <- c(31, 28.25, rep(c(31,30, 31,30, 31), 2))
all.equal(s.y, aggregate(s.m, FUN = mean))         # 0.0013
all.equal(s.y, aggregate(s.m, FUN = weighted.mean, w = ndays)) # 0.0017
```

sunspots

Monthly Sunspot Numbers, 1749–1983

Description

Monthly mean relative sunspot numbers from 1749 to 1983. Collected at Swiss Federal Observatory, Zurich until 1960, then Tokyo Astronomical Observatory.

Usage

sunspots

Format

A time series of monthly data from 1749 to 1983.

Source

See Also

`sunspot.month` has a longer (and a bit different) series, `sunspot.year` is a much shorter one. See there for getting more current sunspot numbers.

Examples

```r
require(graphics)
plot(sunspots, main = "sunspots data", xlab = "Year",
     ylab = "Monthly sunspot numbers")
```
Swiss Fertility and Socioeconomic Indicators (1888) Data

Description

Standardized fertility measure and socio-economic indicators for each of 47 French-speaking provinces of Switzerland at about 1888.

Usage

swiss

Format

A data frame with 47 observations on 6 variables, each of which is in percent, i.e., in [0, 100].

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>

</tbody>
</table>

All variables but ‘Fertility’ give proportions of the population.

Details

(paraphrasing Mosteller and Tukey):

Switzerland, in 1888, was entering a period known as the demographic transition; i.e., its fertility was beginning to fall from the high level typical of underdeveloped countries.

The data collected are for 47 French-speaking “provinces” at about 1888.

Here, all variables are scaled to [0, 100], where in the original, all but “Catholic” were scaled to [0, 1].

Note

Files for all 182 districts in 1888 and other years have been available at https://opr.princeton.edu/archive/pefp/switz.aspx.

They state that variables Examination and Education are averages for 1887, 1888 and 1889.

Theoph

Pharmacokinetics of Theophylline

Description

The Theoph data frame has 132 rows and 5 columns of data from an experiment on the pharmacokinetics of theophylline.

Usage

Theoph

Format

An object of class c("nfnGroupedData", "nfGroupedData", "groupedData", "data.frame") containing the following columns:

Subject an ordered factor with levels 1, ..., 12 identifying the subject on whom the observation was made. The ordering is by increasing maximum concentration of theophylline observed.

Wt weight of the subject (kg).

Dose dose of theophylline administered orally to the subject (mg/kg).

Time time since drug administration when the sample was drawn (hr).

conc theophylline concentration in the sample (mg/L).

Details

Boeckmann, Sheiner and Beal (1994) report data from a study by Dr. Robert Upton of the kinetics of the anti-asthmatic drug theophylline. Twelve subjects were given oral doses of theophylline then serum concentrations were measured at 11 time points over the next 25 hours.

These data are analyzed in Davidian and Giltinan (1995) and Pinheiro and Bates (2000) using a two-compartment open pharmacokinetic model, for which a self-starting model function, SSfo1, is available.

This dataset was originally part of package nlme, and that has methods (including for [, as.data.frame, plot and print) for its grouped-data classes.

Titanic Survival of passengers on the Titanic

Description
This data set provides information on the fate of passengers on the fatal maiden voyage of the ocean liner ‘Titanic’, summarized according to economic status (class), sex, age and survival.

Usage
Titanic

Format
A 4-dimensional array resulting from cross-tabulating 2201 observations on 4 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Class</td>
<td>1st, 2nd, 3rd, Crew</td>
</tr>
<tr>
<td>2</td>
<td>Sex</td>
<td>Male, Female</td>
</tr>
<tr>
<td>3</td>
<td>Age</td>
<td>Child, Adult</td>
</tr>
<tr>
<td>4</td>
<td>Survived</td>
<td>No, Yes</td>
</tr>
</tbody>
</table>

xvals <- seq(0, par("usr")[2], length.out = 55)
lines(xvals, predict(fm1, newdata = list(Time = xvals)),
      col = 4)
Details

The sinking of the Titanic is a famous event, and new books are still being published about it. Many well-known facts—from the proportions of first-class passengers to the ‘women and children first’ policy, and the fact that that policy was not entirely successful in saving the women and children in the third class—are reflected in the survival rates for various classes of passenger.

These data were originally collected by the British Board of Trade in their investigation of the sinking. Note that there is not complete agreement among primary sources as to the exact numbers on board, rescued, or lost.

Due in particular to the very successful film ‘Titanic’, the last years saw a rise in public interest in the Titanic. Very detailed data about the passengers is now available on the Internet, at sites such as Encyclopedia Titanica (https://www.encyclopedia-titanica.org/).

Source

The source provides a data set recording class, sex, age, and survival status for each person on board of the Titanic, and is based on data originally collected by the British Board of Trade and reprinted in:

Examples

require(graphics)
mosaicplot(Titanic, main = "Survival on the Titanic")
## Higher survival rates in children?
apply(Titanic, c(3, 4), sum)
## Higher survival rates in females?
apply(Titanic, c(2, 4), sum)
## Use loglm() in package 'MASS' for further analysis ...

ToothGrowth

The Effect of Vitamin C on Tooth Growth in Guinea Pigs

Description

The response is the length of odontoblasts (cells responsible for tooth growth) in 60 guinea pigs. Each animal received one of three dose levels of vitamin C (0.5, 1, and 2 mg/day) by one of two delivery methods, (orange juice or ascorbic acid (a form of vitamin C and coded as VC).

Usage

ToothGrowth

Format

A data frame with 60 observations on 3 variables.

</table>
treering

Yearly Treering Data, -6000–1979

Description

Contains normalized tree-ring widths in dimensionless units.

Usage

treering

Format

A univariate time series with 7981 observations. The object is of class "ts".

Each tree ring corresponds to one year.

Details

The data were recorded by Donald A. Graybill, 1980, from Gt Basin Bristlecone Pine 2805M, 3726-11810 in Methuselah Walk, California.

Source

References

```

UCBAdmissions

Student Admissions at UC Berkeley

Description

Aggregate data on applicants to graduate school at Berkeley for the six largest departments in 1973 classified by admission and sex.
Usage

UCBAdmissions

Format

A 3-dimensional array resulting from cross-tabulating 4526 observations on 3 variables. The variables and their levels are as follows:

<table>
<thead>
<tr>
<th>No</th>
<th>Name</th>
<th>Levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Admit</td>
<td>Admitted, Rejected</td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>Male, Female</td>
</tr>
<tr>
<td>3</td>
<td>Dept</td>
<td>A, B, C, D, E, F</td>
</tr>
</tbody>
</table>

Details

This data set is frequently used for illustrating Simpson’s paradox, see Bickel et al (1975). At issue is whether the data show evidence of sex bias in admission practices. There were 2691 male applicants, of whom 1198 (44.5%) were admitted, compared with 1835 female applicants of whom 557 (30.4%) were admitted. This gives a sample odds ratio of 1.83, indicating that males were almost twice as likely to be admitted. In fact, graphical methods (as in the example below) or log-linear modelling show that the apparent association between admission and sex stems from differences in the tendency of males and females to apply to the individual departments (females used to apply more to departments with higher rejection rates).

This data set can also be used for illustrating methods for graphical display of categorical data, such as the general-purpose mosaicplot or the fourfoldplot for 2-by-2-by-k tables.

References

Examples

```
require(graphics)
## Data aggregated over departments
apply(UCBAdmissions, c(1, 2), sum)
mosaicplot(apply(UCBAdmissions, c(1, 2), sum),
   main = "Student admissions at UC Berkeley")
## Data for individual departments
opar <- par(mfrow = c(2, 3), oma = c(0, 0, 2, 0))
for(i in 1:6)
   mosaicplot(UCBAdmissions[,,i],
      xlab = "Admit", ylab = "Sex",
      main = paste("Department", LETTERS[i]))
   mtext(expression(bold("Student admissions at UC Berkeley")),
      outer = TRUE, cex = 1.5)
par(opar)
```
Description

UKDriverDeaths is a time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983.

Seatbelts is more information on the same problem.

Usage

UKDriverDeaths

Seatbelts

Format

Seatbelts is a multiple time series, with columns

DriversKilled car drivers killed.

drivers same as UKDriverDeaths.

front front-seat passengers killed or seriously injured.

rear rear-seat passengers killed or seriously injured.

kms distance driven.

PetrolPrice petrol price.

VanKilled number of van (‘light goods vehicle’) drivers.

law 0/1: was the law in effect that month?

Source

References

Examples

require(stats); require(graphics)

## work with pre-seatbelt period to identify a model, use logs

work <- window(log10(UKDriverDeaths), end = 1982+11/12)

par(mfrow = c(3, 1))

plot(work); acf(work); pacf(work)

par(mfrow = c(1, 1))

(fit <- arima(work, c(1, 0, 0), seasonal = list(order = c(1, 0, 0))))
z <- predict(fit, n.ahead = 24)

ts.plot(log10(UKDriverDeaths), z$pred, z$pred+2*z$se, z$pred-2*z$se,
  lty = c(1, 3, 2, 2), col = c("black", "red", "blue", "blue"))

## now see the effect of the explanatory variables
X <- Seatbelts[, c("kms", "PetrolPrice", "law")]
X[, 1] <- log10(X[, 1]) - 4
arima(log10(Seatbelts[, "drivers"]), c(1, 0, 0),

---

**UKgas**  
UK Quarterly Gas Consumption

**Description**
Quarterly UK gas consumption from 1960Q1 to 1986Q4, in millions of therms.

**Usage**
UKgas

**Format**
A quarterly time series of length 108.

**Source**

**Examples**
## maybe str(UKgas) ; plot(UKgas) ...

---

**UKLungDeaths**  
Monthly Deaths from Lung Diseases in the UK

**Description**
Three time series giving the monthly deaths from bronchitis, emphysema and asthma in the UK, 1974–1979, both sexes (ldeaths), males (mdeaths) and females (fdeaths).

**Usage**
ldeaths
fdeaths
mdeaths

**Source**
Examples

```r
require(stats); require(graphics) # for time
plot(ldeaths)
plot(mdeaths, fdeaths)
## Better labels:
yr <- floor(tt <- time(mdeaths))
plot(mdeaths, fdeaths,
    xy.labels = paste(month.abb[12*(tt - yr)], yr-1900, sep = "/"))
```

USAccDeaths

**Accidental Deaths in the US 1973–1978**

A time series giving the monthly totals of accidental deaths in the USA. The values for the first six months of 1979 are 7798 7406 8363 8460 9217 9316.

**Usage**

USAccDeaths

**Source**

USArrests

**Violent Crime Rates by US State**

This data set contains statistics, in arrests per 100,000 residents for assault, murder, and rape in each of the 50 US states in 1973. Also given is the percent of the population living in urban areas.

**Usage**

USArrests

**Format**

A data frame with 50 observations on 4 variables.

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>.1</td>
<td>Murder</td>
<td>numeric</td>
<td>Murder arrests (per 100,000)</td>
</tr>
<tr>
<td>.2</td>
<td>Assault</td>
<td>numeric</td>
<td>Assault arrests (per 100,000)</td>
</tr>
<tr>
<td>.3</td>
<td>UrbanPop</td>
<td>numeric</td>
<td>Percent urban population</td>
</tr>
<tr>
<td>.4</td>
<td>Rape</td>
<td>numeric</td>
<td>Rape arrests (per 100,000)</td>
</tr>
</tbody>
</table>

**Note**

USArrests contains the data as in McNeil’s monograph. For the UrbanPop percentages, a review of the table (No. 21) in the Statistical Abstracts 1975 reveals a transcription error for Maryland
(and that McNeil used the same “round to even” rule that R’s `round()` uses), as found by Daniel S Coven (Arizona).
See the example below on how to correct the error and improve accuracy for the ‘<n>.5’ percentages.

Source

References

See Also

The `state` data sets.

Examples

```r
summary(USArrests)
require(graphics)
pairs(USArrests, panel = panel.smooth, main = "USArrests data")

## Difference between 'USArrests' and its correction
USArrests["Maryland", "UrbanPop"] # 67 -- the transcription error
UA.C <- USArrests
UA.C["Maryland", "UrbanPop"] <- 76.6

## also +/- 0.5 to restore the original <n>.5 percentages
s5u <- c("Colorado", "Florida", "Mississippi", "Wyoming")
s5d <- c("Nebraska", "Pennsylvania")
UA.C[s5u, "UrbanPop"] <- UA.C[s5u, "UrbanPop"] + 0.5
UA.C[s5d, "UrbanPop"] <- UA.C[s5d, "UrbanPop"] - 0.5

## ==> UA.C is now a *C*orrected version of USArrests
```

USJudgeRatings

Lawyers’ Ratings of State Judges in the US Superior Court

Description

Lawyers’ ratings of state judges in the US Superior Court.

Usage

`USJudgeRatings`

Format

A data frame containing 43 observations on 12 numeric variables.
[.1] CONT Number of contacts of lawyer with judge.
[.2] INTG Judicial integrity.
[.3] DMNR Demeanor.
[.5] CFMG Case flow managing.
[.6] DECI Prompt decisions.
[.7] PREP Preparation for trial.
[.8] FAMI Familiarity with law.
[.9] ORAL Sound oral rulings.
[.10] WRIT Sound written rulings.
[.11] PHYS Physical ability.
[.12] RTEN Worthy of retention.

Source

New Haven Register, 14 January, 1977 (from John Hartigan).

Examples

require(graphics)
pairs(USJudgeRatings, main = "USJudgeRatings data")

USPersonalExpenditure Personal Expenditure Data

Description

This data set consists of United States personal expenditures (in billions of dollars) in the categories; food and tobacco, household operation, medical and health, personal care, and private education for the years 1940, 1945, 1950, 1955 and 1960.

Usage

USPersonalExpenditure

Format

A matrix with 5 rows and 5 columns.

Source

References

Examples

require(stats) # for medpolish
USPersonalExpenditure
medpolish(log10(USPersonalExpenditure))
uspop

*Populations Recorded by the US Census*

**Description**

This data set gives the population of the United States (in millions) as recorded by the decennial census for the period 1790–1970.

**Usage**

uspop

**Format**

A time series of 19 values.

**Source**

**Examples**

```r
require(graphics)
plot(uspop, log = "y", main = "uspop data", xlab = "Year",
     ylab = "U.S. Population (millions)")
```

---

**VADeaths**

*Death Rates in Virginia (1940)*

**Description**

Death rates per 1000 in Virginia in 1940.

**Usage**

VADeaths

**Format**

A matrix with 5 rows and 4 columns.

**Details**

The death rates are measured per 1000 population per year. They are cross-classified by age group (rows) and population group (columns). The age groups are: 50–54, 55–59, 60–64, 65–69, 70–74 and the population groups are Rural/Male, Rural/Female, Urban/Male and Urban/Female.

This provides a rather nice 3-way analysis of variance example.
Source

References

Examples

```r
require(stats); require(graphics)
n <- length(dr <- c(VADeaths))
nam <- names(VADeaths)
d.VAD <- data.frame(n)
  Drate = dr,
  age = rep(ordered(rownames(VADeaths)), length.out = n),
  gender = gl(2, 5, n, labels = c("M", "F")),
  site = gl(2, 10, labels = c("rural", "urban"))
coplot(Drate ~ as.numeric(age) | gender * site, data = d.VAD,
       panel = panel.smooth, xlab = "VADeaths data - Given: gender")
summary(aov.VAD <- aov(Drate ~ .^2, data = d.VAD))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0))
plot(aov.VAD)
par(opar)
```

volcano

*Topographic Information on Auckland’s Maunga Whau Volcano*

Description

Maunga Whau (Mt Eden) is one of about 50 volcanos in the Auckland volcanic field. This data set gives topographic information for Maunga Whau on a 10m by 10m grid.

Usage

```r
volcano
```

Format

A matrix with 87 rows and 61 columns, rows corresponding to grid lines running east to west and columns to grid lines running south to north.

Source

Digitized from a topographic map by Ross Ihaka. These data should not be regarded as accurate.

See Also

`filled.contour` for a nice plot.
Examples

```r
require(grDevices); require(graphics)
filled.contour(volcano, color.palette = terrain.colors, asp = 1)
title(main = "volcano data: filled contour map")
```

warbreaks  
*The Number of Breaks in Yarn during Weaving*

Description

This data set gives the number of warp breaks per loom, where a loom corresponds to a fixed length of yarn.

Usage

warbreaks

Format

A data frame with 54 observations on 3 variables.

```
[,1] breaks   numeric The number of breaks
[,2] wool     factor The type of wool (A or B)
[,3] tension  factor The level of tension (L, M, H)
```

There are measurements on 9 looms for each of the six types of warp (AL, AM, AH, BL, BM, BH).

Source

References

See Also

`xtabs` for ways to display these data as a table.

Examples

```r
require(stats); require(graphics)
summary(warbreaks)
opar <- par(mfrow = c(1, 2), oma = c(0, 0, 1.1, 0))
plot(breaks ~ tension, data = warbreaks, col = "lightgray",
     varwidth = TRUE, subset = wool == "A", main = "Wool A")
plot(breaks ~ tension, data = warbreaks, col = "lightgray",
     varwidth = TRUE, subset = wool == "B", main = "Wool B")
mtext("warbreaks data", side = 3, outer = TRUE)
par(opar)
summary(fm1 <- lm(breaks ~ wool*tension, data = warbreaks))
```
Average Heights and Weights for American Women

Description
This data set gives the average heights and weights for American women aged 30–39.

Usage
women

Format
A data frame with 15 observations on 2 variables.

<p>| | |</p>
<table>
<thead>
<tr>

grDevices-package

The R Graphics Devices and Support for Colours and Fonts

Description

Graphics devices and support for base and grid graphics

Details

This package contains functions which support both base and grid graphics.

For a complete list of functions, use library(help = "grDevices").

Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

---

adjustcolor

Adjust Colors in One or More Directions Conveniently.

Description

Adjust or modify a vector of colors by “turning knobs” on one or more coordinates in (r, g, b, α) space, typically by up or down scaling them.

Usage

adjustcolor(col, alpha.f = 1, red.f = 1, green.f = 1, blue.f = 1, offset = c(0, 0, 0, 0),
            transform = diag(c(red.f, green.f, blue.f, alpha.f)))
Arguments

- **col** vector of colors, in any format that `col2rgb()` accepts
- **alpha.f** factor modifying the opacity alpha; typically in [0,1]
- **red.f, green.f, blue.f** factors modifying the “red-“, “green-“ or “blue-“ness of the colors, respectively.
- **offset**
- **transform**

Value

A color vector of the same length as `col`, effectively the result of `rgb()`.

See Also

`rgb, col2rgb`. For more sophisticated color constructions: `convertColor`

Examples

```r
## Illustrative examples:
opal <- palette("default")
stopifnot(identical(adjustcolor(1:8, 0.75),
                      adjustcolor(palette(), 0.75)))
cbind(palette(), adjustcolor(1:8, 0.75))

## alpha = 1/2 * previous alpha --> opaque colors
x <- palette(adjustcolor(palette(), 0.5))
sines <- outer(1:20, 1:4, function(x, y) sin(x / 20 * pi * y))
matplot(sines, type = "b", pch = 21:23, col = 2:5, bg = 2:5,
       main = "Using an 'opaque ('translucent') color palette")

x. <- adjustcolor(x, offset = c(0.5, 0.5, 0.5, 0), # <- "more white"
                   transform = diag(c(.7, .7, .7, 0.6)))
cbind(x, x.)

op <- par(bg = adjustcolor("goldenrod", offset = -rep(.4, 4)), xpd = NA)
plot(0:9, 0:9, type = "n", axes = FALSE, xlab = ",", ylab = ",",
     main = "adjustcolor() -> translucent")
text(1:8, labels = paste0(x,"++"), col = x., cex = 8)
par(op)

## and

(M <- cbind( rbind( matrix(1/3, 3, 3), 0), c(0, 0, 0, 1)))
adjustcolor(x, transform = M)

## revert to previous palette: active
palette(opal)
```
as.graphicsAnnot  Coerce an Object for Graphics Annotation

Description

Coerce an R object into a form suitable for graphics annotation.

Usage

as.graphicsAnnot(x)

Arguments

x  
an R object

Details

Expressions, calls and names (as used by `plotmath`) are passed through unchanged. All other objects
with an explicit class (as determined by `is.object`) are coerced by `as.character` to character
vectors.

All the `graphics` and `grid` functions which use this coerce calls and names to expressions internally.

Value

A language object or a character vector.

as.raster  Create a Raster Object

Description

Functions to create a raster object (representing a bitmap image) and coerce other objects to a raster
object.

Usage

is.raster(x)
as.raster(x)

## S3 method for class 'matrix'
as.raster(x, max = 1, ...)

## S3 method for class 'array'
as.raster(x, max = 1, ...)

## S3 method for class 'logical'
as.raster(x, max = 1, ...)

## S3 method for class 'numeric'
as.raster(x, max = 1, ...)

## S3 method for class 'character'
as.raster(x, max = 1, ...)

## S3 method for class 'raw'
as.raster(x, max = 255L, ...)
Arguments

\texttt{x} \hspace{1cm} \text{any R object.}

\texttt{max} \hspace{1cm} \text{number giving the maximum of the color values range.}

\texttt{...} \hspace{1cm} \text{further arguments passed to or from other methods.}

Details

An object of class "raster" is a matrix of colour values as given by \texttt{rgb} representing a bitmap image.

It is not expected that the user will need to call these functions directly; functions to render bitmap images in graphics packages will make use of the \texttt{as.raster()} function to generate a raster object from their input.

The \texttt{as.raster()} function is (S3) generic so methods can be written to convert other R objects to a raster object.

The default implementation for numeric matrices interprets scalar values on black-to-white scale.

Raster objects can be subsetted like a matrix and it is possible to assign to a subset of a raster object.

There is a method for converting a raster object to a \texttt{matrix} (of colour strings).

Raster objects can be compared for equality or inequality (with each other or with a colour string).

There is an \texttt{is.na} method which returns a logical matrix of the same dimensions as the raster object.

Note that \texttt{NA} values are interpreted as the fully transparent colour by some (but not all) graphics devices.

Value

For \texttt{as.raster()}, a raster object.

For \texttt{is.raster()}, a logical indicating whether \texttt{x} is a raster object.

Examples

# A red gradient
as.raster(matrix(hcl(0, 80, seq(50, 80, 10)),
                nrow = 4, ncol = 5))

# Vectors are 1-column matrices ...
# character vectors are color names ...
as.raster(hcl(0, 80, seq(50, 80, 10)))
# numeric vectors are greyscale ...
as.raster(1:5, max = 5)
# logical vectors are black and white ...
as.raster(1:10 %% 2 == 0)

# ... unless nrow/ncol are supplied ...
as.raster(1:10 %% 2 == 0, nrow = 1)

# Matrix can also be logical or numeric (or raw) ...
Compute Pretty Axis Tick Scales

Description

Compute pretty axis scales and tick mark locations, the same way as traditional R graphics do it. This is interesting particularly for log scale axes.

Usage

axisTicks(usr, log, axp = NULL, nint = 5)
.axisPars(usr, log = FALSE, nintLog = 5)

Arguments

usr numeric vector of length 2, with c(min, max) axis extents.
log logical indicating if a log scale is (thought to be) in use.
axp numeric vector of length 3, c(mi, ma, n.), with identical meaning to par("?axp") (where ? is x or y), namely “pretty” axis extents, and an integer code n..
nint, nintLog positive integer value indicating (approximately) the desired number of intervals. nintLog is used only for the case log = TRUE.

Details

axisTicks(usr, *) calls .axisPars(usr, ..) when axp is missing (or NULL).
Value

axisTicks() returns a numeric vector of potential axis tick locations, of length approximately \( n_{\text{int}} + 1 \).

.axisPars() returns a list with components

- \( \text{axp} \) numeric vector of length 2, \((\text{min.}, \text{max.})\), of pretty axis extents.
- \( n \) integer (code), with the same meaning as \( \text{par}("?axp")[3] \).

See Also

- axisTicks; axis, and par (from the graphics package).

Examples

```r
##--- Demonstrating correspondence between graphics' 
##--- axis() and the graphics-engine agnostic axisTicks() :

require("graphics")

plot(10*(0:10)); (pu <- par("usr"))
aX <- function(side, at, ...)
   axis(side, at = at, labels = FALSE, lwd.ticks = 2, col.ticks = 2, tck = 0.05, ...)
aX(1, print(xa <- axisTicks(pu[1:2], log = FALSE))) # x axis
aX(2, print(ya <- axisTicks(pu[3:4], log = FALSE))) # y axis
axisTicks(pu[3:4], log = FALSE, n = 10)

plot(10*(0:10), log = "y"); (pu <- par("usr"))
aX(2, print(ya <- axisTicks(pu[3:4], log = TRUE))) # y axis

plot(2^(0:9), log = "y"); (pu <- par("usr"))
aX(2, print(ya <- axisTicks(pu[3:4], log = TRUE))) # y axis

```

---

**boxplot.stats**

**Box Plot Statistics**

Description

This function is typically called by another function to gather the statistics necessary for producing box plots, but may be invoked separately.

Usage

```r
boxplot.stats(x, coef = 1.5, do.conf = TRUE, do.out = TRUE)
```

Arguments

- \( x \) a numeric vector for which the boxplot will be constructed (NAs and NaNs are allowed and omitted).
boxplot.stats

coef

this determines how far the plot 'whiskers' extend out from the box. If coef is positive, the whiskers extend to the most extreme data point which is no more than coef times the length of the box away from the box. A value of zero causes the whiskers to extend to the data extremes (and no outliers be returned).

do.conf, do.out

logicals; if FALSE, the conf or out component respectively will be empty in the result.

Details

The two 'hinges' are versions of the first and third quartile, i.e., close to quantile(x, c(1,3)/4). The hinges equal the quartiles for odd n (where n <- length(x)) and differ for even n. Whereas the quartiles only equal observations for n %% 4 == 1 (n ≡ 1 mod 4), the hinges do so additionally for n %% 4 == 2 (n ≡ 2 mod 4), and are in the middle of two observations otherwise.

The notches (if requested) extend to +/-1.58 IQR/sqrt(n). This seems to be based on the same calculations as the formula with 1.57 in Chambers et al (1983, p. 62), given in McGill et al (1978, p. 16). They are based on asymptotic normality of the median and roughly equal sample sizes for the two medians being compared, and are said to be rather insensitive to the underlying distributions of the samples. The idea appears to be to give roughly a 95% confidence interval for the difference in two medians.

Value

List with named components as follows:

stats a vector of length 5, containing the extreme of the lower whisker, the lower 'hinge', the median, the upper 'hinge' and the extreme of the upper whisker.

n the number of non-NA observations in the sample.

cnf the lower and upper extremes of the 'notch' (if(do.conf)). See the details.

out the values of any data points which lie beyond the extremes of the whiskers (if(do.out)).

Note that $stats and $conf are sorted in increasing order, unlike S, and that $n and $out include any +/- Inf values.

References

See Also

fivenum, boxplot, bxp.
Examples

```r
require(stats)
x <- c(1:100, 1000)
(b1 <- boxplot.stats(x))
(b2 <- boxplot.stats(x, do.conf = FALSE, do.out = FALSE))
stopifnot(b1 $ stats == b2 $ stats) # do.out = FALSE is still robust
boxplot.stats(x, coef = 3, do.conf = FALSE)
## no outlier treatment:
boxplot.stats(x, coef = 0)

boxplot.stats(c(x, NA)) # slight change : n is 101
(r <- boxplot.stats(c(x, -1:1/0)))
stopifnot(r$out == c(1000, -Inf, Inf))
```

Description

Graphics devices for SVG, PDF and PostScript graphics files using the cairo graphics API.

Usage

```r
svg(filename = if(onefile) "Rplots.svg" else "Rplot%03d.svg",
     width = 7, height = 7, pointsize = 12,
     onefile = FALSE, family = "sans", bg = "white",
     antialias = c("default", "none", "gray", "subpixel"))

cairo_pdf(filename = if(onefile) "Rplots.pdf" else "Rplot%03d.pdf",
          width = 7, height = 7, pointsize = 12,
          onefile = FALSE, family = "sans", bg = "white",
          antialias = c("default", "none", "gray", "subpixel"),
          fallback_resolution = 300)

cairo_ps(filename = if(onefile) "Rplots.ps" else "Rplot%03d.ps",
         width = 7, height = 7, pointsize = 12,
         onefile = FALSE, family = "sans", bg = "white",
         antialias = c("default", "none", "gray", "subpixel"),
         fallback_resolution = 300)
```

Arguments

- **filename**: the name of the output file. The page number is substituted if a C integer format is included in the character string, as in the default. (The result must be less than PATH_MAX characters long, and may be truncated if not. See `postscript` for further details.) Tilde expansion is performed where supported by the platform.
- **width**: the width of the device in inches.
height: the height of the device in inches.

pointsize: the default pointsize of plotted text (in big points).

onefile: should all plots appear in one file or in separate files?

family: one of the device-independent font families, "sans", "serif" and "mono", or a character string to specify a font family to be searched for in a system-dependent way. See the 'Cairo fonts' section in the help for X11.

bg: the initial background colour: can be overridden by setting par("bg").

antialias: string, the type of anti-aliasing (if any) to be used; defaults to "default".

fallback_resolution: numeric: the resolution in dpi used when falling back to bitmap output. Prior to R 3.3.0 this depended on the cairo implementation but was commonly 300.

Details

SVG (Scalar Vector Graphics) is a W3C standard for vector graphics. See http://www.w3.org/Graphics/SVG/. The output from svg is SVG version 1.1 for onefile = FALSE (the default), otherwise SVG 1.2. (Few SVG viewers are capable of displaying multi-page SVG files.)

Note that unlike postscript and pdf, cairo_pdf and cairo_ps sometimes record bitmaps and not vector graphics. On the other hand, they can (on suitable platforms) include a much wider range of UTF-8 glyphs, and embed the fonts used.

The output produced by cairo_ps(onefile = FALSE) will be encapsulated postscript on a platform with cairo >= 1.6.

R can be compiled without support for any of these devices: this will be reported if you attempt to use them on a system where they are not supported. They all require cairo version 1.2 (from 2006) or later.

If you plot more than one page on one of these devices and do not include something like %d for the sequence number in file (or set onefile = TRUE) the file will contain the last page plotted.

There is full support of semi-transparency, but using this is one of the things liable to trigger bitmap output (and will always do so for cairo_ps).

Value

A plot device is opened: nothing is returned to the R interpreter.

Anti-aliasing

Anti-aliasing is applied to both graphics and fonts. It is generally preferable for lines and text, but can lead to undesirable effects for fills, e.g. for image plots, and so is never used for fills.

antialias = "default" is in principle platform-dependent, but seems most often equivalent to antialias = "gray".

Conventions

This section describes the implementation of the conventions for graphics devices set out in the "R Internals Manual".

- The default device size is in pixels (svg) or inches.
- Font sizes are in big points.
- The default font family is Helvetica.
check.options

Description

Utility function for setting options with some consistency checks. The attributes of the new settings in new are checked for consistency with the model (often default) list in name.opt.

Usage

check.options(new, name.opt, reset = FALSE, assign.opt = FALSE, envir = .GlobalEnv, check.attributes = c("mode", "length"), override.check = FALSE)

Arguments

new a named list
name.opt character with the name of R object containing the default list.
reset logical; if TRUE, reset the options from name.opt. If there is more than one R object with name name.opt, remove the first one in the search() path.
assign.opt logical; if TRUE, assign the ...
envir the environment used for get and assign.
check.attributes character containing the attributes which check.options should check.
override.check logical vector of length length(new) (or 1 which entails recycling). For those new[i] where override.check[i] == TRUE, the checks are overridden and the changes made anyway.

Value

A list of components with the same names as the one called name.opt. The values of the components are changed from the new list, as long as these pass the checks (when these are not overridden according to override.check).

Note

Cairo 1.2.4 (seen in Centos/RHEL 5) is known to give incorrect SVG output.

In principle these devices are independent of X11 (as is seen by their presence on Windows). But on a Unix-alike the cairo libraries may be distributed as part of the X11 system and hence that (on macOS, XQuartz) may need to be installed.
chull

Note

Option "names" is exempt from all the checks or warnings, as in the application it can be NULL or a variable-length character vector.

Author(s)

Martin Maechler

See Also

ps.options and pdf.options, which use check.options.

Examples

(L1 <- list(a = 1:3, b = pi, ch = "CH"))
check.options(list(a = 0:2), name.opt = "L1")
check.options(NULL, reset = TRUE, name.opt = "L1")

chull

Compute Convex Hull of a Set of Points

Description

Computes the subset of points which lie on the convex hull of the set of points specified.

Usage

chull(x, y = NULL)

Arguments

x, y

coordinate vectors of points. This can be specified as two vectors x and y, a 2-column matrix x, a list x with two components, etc, see xy.coords.

Details

xy.coords is used to interpret the specification of the points. Infinite, missing and NaN values are not allowed.

The algorithm is that given by Eddy (1977).

Value

An integer vector giving the indices of the unique points lying on the convex hull, in clockwise order. (The first will be returned for duplicate points.)

References

See Also

xy.coords, polygon

Examples

X <- matrix(stats::rnorm(2000), ncol = 2)
chull(X)

## Not run:
# Example usage from graphics package
plot(X, cex = 0.5)
hpts <- chull(X)
hpts <- c(hpts, hpts[1])
lines(X[hpts, ])

## End(Not run)

---

cm

Unit Transformation

Description

Translates from inches to cm (centimeters).

Usage

cm(x)

Arguments

x numeric vector

Examples

cm(1) # = 2.54

## Translate *from* cm *to* inches:
10 / cm(1) # -> 10cm are 3.937 inches

---

col2rgb

Color to RGB Conversion

Description

R color to RGB (red/green/blue) conversion.

Usage

col2rgb(col, alpha = FALSE)
Arguments

col  vector of any of the three kinds of R color specifications, i.e., either a color name (as listed by `colors()`), a hexadecimal string of the form "#rrggbbaa" or "#rrggbbaa" (see `rgb`), or a positive integer i meaning `palette()[i]`.

alpha  logical value indicating whether the alpha channel (opacity) values should be returned.

Details

NA (as integer or character) and "NA" mean transparent.

Values of `col` not of one of these types are coerced: real vectors are coerced to integer and other types to character. (factors are coerced to character: in all other cases the class is ignored when doing the coercion.)

Zero and negative values of `col` are an error.

Value

An integer matrix with three or four (for `alpha = TRUE`) rows and number of columns the length of `col`. If `col` has names these are used as the column names of the return value.

Author(s)

Martin Maechler and the R core team.

See Also

`rgb, colors, palette`, etc.

The newer, more flexible interface, `convertColor()`.

Examples

col2rgb("peachpuff")
col2rgb(c(blu = "royalblue", reddish = "tomato")) # note: colnames

col2rgb(1:8) # the ones from the palette() (if the default)
col2rgb(paste0("gold", 1:4))
col2rgb("#08a0ff")

# all three kinds of color specifications:
col2rgb(c(red = "red", hex = "#abcdef"))
col2rgb(c(palette = 1:3))

#-- NON-INTRODUCTORY examples --
grC <- col2rgb(paste0("gray", 0:100))
table(print(diff(grC["red",]))) # '2' or '3': almost equidistant

# The 'named' grays are in between ("slate gray" is not gray, strictly)
col2rgb(c(g66 = "gray66", darkg = "dark gray", g67 = "gray67",
g74 = "gray74", gray = "gray", g75 = "gray75",
g82 = "gray82", light = "light gray", g83 = "gray83"))

crgb <- col2rgb(cc <- colors())
colnames(crgb) <- cc
t(crgb) # The whole table

codes <- c(256^(2:0) %*% crgb) # = internal codes  
## How many names are 'aliases' of each other:
length(tcc <- table(codes)) # 502
## All the multiply named colors:
cl <- lapply(mult, function(m) tcc[codes == m])
names(cl) <- apply(col2rgb(sapply(cl, function(x)x[1])),
                  2, function(n)paste(n, collapse = ","))
utils::str(cl)
## Not run:
if(require(xgobi)) { ## Look at the color cube dynamically : 
  tc <- t(crgb[, !duplicated(codes)])
  table(is.gray <- tc[,1] == tc[,2] & tc[,2] == tc[,3]) # (397, 105)
  xgobi(tc, color = c("gold", "gray")[1 + is.gray])
}
## End(Not run)

colorRamp

Description

These functions return functions that interpolate a set of given colors to create new color palettes (like topo.colors) and color ramps, functions that map the interval [0, 1] to colors (like grey).

Usage

colorRamp(colors, bias = 1, space = c("rgb", "Lab"),
          interpolate = c("linear", "spline"), alpha = FALSE)
colorRampPalette(colors, ...)

Arguments

colors colors to interpolate; must be a valid argument to col2rgb().
bias a positive number. Higher values give more widely spaced colors at the high end.
space a character string; interpolation in RGB or CIE Lab color spaces.
interpolate use spline or linear interpolation.
alpha logical: should alpha channel (opacity) values be returned? It is an error to give a true value if space is specified.
... arguments to pass to colorRamp.
**Details**

The CIE Lab color space is approximately perceptually uniform, and so gives smoother and more uniform color ramps. On the other hand, palettes that vary from one hue to another via white may have a more symmetrical appearance in RGB space.

The conversion formulas in this function do not appear to be completely accurate and the color ramp may not reach the extreme values in Lab space. Future changes in the R color model may change the colors produced with `space = "Lab"`.

**Value**

`colorRamp` returns a function with argument a vector of values between 0 and 1 that are mapped to a numeric matrix of RGB color values with one row per color and 3 or 4 columns.

`colorRampPalette` returns a function that takes an integer argument (the required number of colors) and returns a character vector of colors (see `rgb`) interpolating the given sequence (similar to `heat.colors` or `terrain.colors`).

**See Also**

Good starting points for interpolation are the “sequential” and “diverging” ColorBrewer palettes in the `RColorBrewer` package.

`splinefun` or `approxfun` are used for interpolation.

**Examples**

```r
## Both return a *function* :
colorRamp(c("red", "green"))( (0:4)/4 ) ## (x) , x in [0,1]
colorRampPalette(c("blue", "red"))( 4 ) ## (n)
## a ramp in opacity of blue values
colorRampPalette(c(rgb(0,0,1,1), rgb(0,0,1,0)), alpha = TRUE)(8)
require(graphics)
## Here space="rgb" gives palettes that vary only in saturation, 
## as intended.
## With space="Lab" the steps are more uniform, but the hues 
## are slightly purple.
filled.contour(volcano,
    color.palette =
    colorRampPalette(c("red", "white", "blue")),
    asp = 1)
filled.contour(volcano,
    color.palette =
    colorRampPalette(c("red", "white", "blue"),
                     space = "Lab"),
    asp = 1)
## Interpolating a 'sequential' ColorBrewer palette
YlOrBr <- c("#FFFFD4", "#FED98E", "#FE9929", "#D95F0E", "#993404")
filled.contour(volcano,
    color.palette = colorRampPalette(YlOrBr, space = "Lab"),
    asp = 1)
filled.contour(volcano,
    color.palette = colorRampPalette(YlOrBr, space = "Lab",
                           bias = 0.5),
```

```
colors

Description
Returns the built-in color names which \texttt{R} knows about.

Usage

\begin{verbatim}
  colors (distinct = FALSE)
  colours(distinct = FALSE)
\end{verbatim}

Arguments

\begin{verbatim}
  distinct   logical indicating if the colors returned should all be distinct; e.g., "snow" and 
             "snow1" are effectively the same point in the \((0 : 255)^3\) RGB space.
\end{verbatim}

Details
These color names can be used with a \texttt{col=} specification in graphics functions.
An even wider variety of colors can be created with primitives \texttt{rgb}, \texttt{hsv} and \texttt{hcl}, or the derived \texttt{rainbow}, \texttt{heat.colors}, etc.

Value
A character vector containing all the built-in color names.

See Also
\texttt{palette} for setting the ‘palette’ of colors for \texttt{par(col=<num>)}; \texttt{rgb}, \texttt{hsv}, \texttt{hcl}, \texttt{gray}; \texttt{rainbow} for a nice example; and \texttt{heat.colors}, \texttt{topo.colors} for images.
\texttt{col2rgb} for translating to RGB numbers and extended examples.
Examples

cl <- colors()
length(cl); cl[1:20]

length(cl. <- colors(TRUE))
## only 502 of the 657 named ones

## ----------- Show all named colors and more:
demo("colors")
## -----------

describe the function and its arguments

Description

Calculate contour lines for a given set of data.

Usage

contourLines(x = seq(0, 1, length.out = nrow(z)),
            y = seq(0, 1, length.out = ncol(z)),
            z, nlevels = 10,
            levels = pretty(range(z, na.rm = TRUE), nlevels))

Arguments

x, y            locations of grid lines at which the values in z are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively. If the list has component z this is used for z.

z               a matrix containing the values to be plotted (NAs are allowed). Note that x can be used instead of z for convenience.

nlevels         number of contour levels desired iff levels is not supplied.

levels          numeric vector of levels at which to draw contour lines.

Details

contourLines draws nothing, but returns a set of contour lines.

There is currently no documentation about the algorithm. The source code is in `R_HOME/src/main/plot3d.c`.

Value

A list of contours. Each contour is a list with elements:

level           The contour level.

x               The x-coordinates of the contour.

y               The y-coordinates of the contour.
convertColor

See Also

options("max.contour.segments") for the maximal complexity of a single contour line. 
contour.

Examples

x <- 10*1:nrow(volcano)
y <- 10*1:ncol(volcano)
contourlines(x, y, volcano)

convertColor  Convert between Colour Spaces

Description

Convert colours between their representations in standard colour spaces.

Usage

convertColor(color, from, to, from.ref.white, to.ref.white,
scale.in = 1, scale.out = 1, clip = TRUE)

Arguments

color  A matrix whose rows specify colors.
from, to  Input and output color spaces. See ‘Details’ below.
from.ref.white, to.ref.white  Reference whites or NULL if these are built in to the definition, as for RGB spaces. D65 is the default, see ‘Details’ for others.
scale.in, scale.out  Input is divided by scale.in, output is multiplied by scale.out. Use NULL to suppress scaling when input or output is not numeric.
clip  If TRUE, truncate RGB output to [0,1], FALSE return out-of-range RGB, NA set out of range colors to NaN.

Details

Color spaces are specified by objects of class colorConverter, created by colorConverter or make.rgb. Built-in color spaces may be referenced by strings: "XYZ", "sRGB", "Apple RGB", "CIE RGB", "Lab", "Luv". The converters for these colour spaces are in the object colorspaces.

The "sRGB" color space is that used by standard PC monitors. "Apple RGB" is used by Apple monitors. "Lab" and "Luv" are approximately perceptually uniform spaces standardized by the Commission Internationale d’Eclairage. XYZ is a 1931 CIE standard capable of representing all visible colors (and then some), but not in a perceptually uniform way.

The Lab and Luv spaces describe colors of objects, and so require the specification of a reference ‘white light’ color. Illuminant D65 is a standard indirect daylight, Illuminant D50 is close to direct sunlight, and Illuminant A is the light from a standard incandescent bulb. Other standard CIE illuminants supported are B, C, E and D55. RGB colour spaces are defined relative to a particular reference
white, and can be only approximately translated to other reference whites. The Bradford chromatic adaptation algorithm is used for this.

The RGB color spaces are specific to a particular class of display. An RGB space cannot represent all colors, and the clip option controls what is done to out-of-range colors.

For the named color spaces `color` must be a matrix of values in the `from` color space: in particular opaque colors.

**Value**

A 3-column matrix whose rows specify the colors.

**References**

**See Also**

`col2rgb` and `colors` for ways to specify colors in graphics.

`make.rgb` for specifying other colour spaces.

**Examples**

```r
## The displayable colors from four planes of Lab space
ab <- expand.grid(a = (-10:15)*10, b = (-15:10)*10)
require(graphics); require(stats) # for na.omit
par(mfrow = c(2, 2), mar = .1+c(3, 3, 3, .5), mgp = c(2, .8, 0))
Lab <- cbind(L = 20, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
clipped <- attr(na.omit(srgb), "na.action")
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:10)*10, matrix(1:(26*26), ncol = 26), col = cols,
     xlab = "a", ylab = "b", main = "Lab: L=20")
Lab <- cbind(L = 40, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
clipped <- attr(na.omit(srgb), "na.action")
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:10)*10, matrix(1:(26*26), ncol = 26), col = cols,
     xlab = "a", ylab = "b", main = "Lab: L=40")
Lab <- cbind(L = 60, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
clipped <- attr(na.omit(srgb), "na.action")
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:10)*10, matrix(1:(26*26), ncol = 26), col = cols,
     xlab = "a", ylab = "b", main = "Lab: L=60")
Lab <- cbind(L = 80, ab)
srgb <- convertColor(Lab, from = "Lab", to = "sRGB", clip = NA)
```
clipped <- attr(NA.omit(srgb), "na.action")
srgb[clipped, ] <- 0
cols <- rgb(srgb[, 1], srgb[, 2], srgb[, 3])
image((-10:15)*10, (-15:10)*10, matrix(1:(26*26), nrow = 26), col = cols, 
  xlab = "a", ylab = "b", main = "Lab: L=80")
cols <- t(col2rgb(palette())); rownames(cols) <- palette(); cols
zapsmall(lab <- convertColor(cols, from = "sRGB", to = "Lab", scale.in = 255))
stopifnot(all.equal(cols, # converting back.. getting the original:
  round(convertColor(lab, from = "Lab", to = "sRGB", scale.out = 255)),
  check.attributes = FALSE))

densCols

Colors for Smooth Density Plots

Description

densCols produces a vector containing colors which encode the local densities at each point in a scatterplot.

Usage

densCols(x, y = NULL, nbin = 128, bandwidth,
  colramp = colorRampPalette(blues9[-(1:3)]))
blues9

Arguments

x, y the x and y arguments provide the x and y coordinates of the points. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details. If supplied separately, they must be of the same length.
nbin numeric vector of length one (for both directions) or two (for x and y separately) specifying the number of equally spaced grid points for the density estimation; directly used as gridsize in bkde2D().
bandwidth numeric vector (length 1 or 2) of smoothing bandwidth(s). If missing, a more or less useful default is used. bandwidth is subsequently passed to function bkde2D.
colramp function accepting an integer n as an argument and returning n colors.

Details

densCols computes and returns the set of colors that will be used in plotting, calling bkde2D(*, bandwidth, gridsize = nbin, ..) from package KernSmooth.
blues9 is a set of 9 color shades of blue used as the default in plotting.

Value

densCols returns a vector of length nrow(x) that contains colors to be used in a subsequent scatterplot. Each color represents the local density around the corresponding point.
Author(s)
Florian Hahne at FHCRC, originally

See Also
bkde2D from package KernSmooth; further, smoothScatter() (package graphics) which builds on the same computations as densCols.

Examples
x1 <- matrix(rnorm(1e3), ncol = 2)
x2 <- matrix(rnorm(1e3, mean = 3, sd = 1.5), ncol = 2)
x <- rbind(x1, x2)
dcols <- densCols(x)
graphics::plot(x, col = dcols, pch = 20, main = "n = 1000")

Description
These functions provide control over multiple graphics devices.

Usage
dev.cur()
dev.list()
dev.next(which = dev.cur())
dev.prev(which = dev.cur())
dev.off(which = dev.cur())
dev.set(which = dev.next())
dev.new(..., noRStudioGD = FALSE)
graphics.off()

Arguments
which An integer specifying a device number.
... arguments to be passed to the device selected.
norRStudioGD Do not use the RStudio graphics device even if specified as the default device: it does not accept arguments such as width and height.

Details
Only one device is the ‘active’ device: this is the device in which all graphics operations occur. There is a "null device" which is always open but is really a placeholder: any attempt to use it will open a new device specified by getOption("device").

Devices are associated with a name (e.g., "X11" or "postscript") and a number in the range 1 to 63; the "null device" is always device 1. Once a device has been opened the null device is not considered as a possible active device. There is a list of open devices, and this is considered as a
circular list not including the null device. dev.next and dev.prev select the next open device in the appropriate direction, unless no device is open.

dev.off shuts down the specified (by default the current) device. If the current device is shut down and any other devices are open, the next open device is made current. It is an error to attempt to shut down device 1. graphics.off() shuts down all open graphics devices. Normal termination of a session runs the internal equivalent of graphics.off().

dev.set makes the specified device the active device. If there is no device with that number, it is equivalent to dev.next. If which = 1 it opens a new device and selects that.

dev.new opens a new device. Normally R will open a new device automatically when needed, but this enables you to open further devices in a platform-independent way. (For which device is used see getOption("device").) Note that care is needed with file-based devices such as pdf and postscript and in that case file names such as 'Rplots.pdf', 'Rplots1.pdf', ...., 'Rplots999.pdf' are tried in turn. Only named arguments are passed to the device, and then only if they match the argument list of the device. Even so, care is needed with the interpretation of e.g. width, and for the standard bitmap devices units = "in", res = 72 is forced if neither is supplied but both width and height are.

Value

dev.cur returns a length-one named integer vector giving the number and name of the active device, or 1, the null device, if none is active.

dev.list returns the numbers of all open devices, except device 1, the null device. This is a numeric vector with a names attribute giving the device names, or NULL if there is no open device.

dev.next and dev.prev return the number and name of the next / previous device in the list of devices. This will be the null device if and only if there are no open devices.

dev.off returns the number and name of the new active device (after the specified device has been shut down).

dev.set returns the number and name of the new active device.

dev.new returns the return value of the device opened, usually invisible NULL.

layout and its links for setting up plotting regions on the current device.

Examples

## Not run: ## Unix-specific example
x11()
plot(1:10)
x11()
plot(rnorm(10))
dev.set(dev.prev())
abline(0, 1) # through the 1:10 points
dev.set(dev.next())
abline(h = 0, col = "gray") # for the residual plot
dev.set(dev.prev())
dev.off(); dev.off() #- close the two X devices

## End(Not run)
dev.capabilities

Query Capabilities of the Current Graphics Device

Description
Query the capabilities of the current graphics device.

Usage
dev.capabilities(what = NULL)

Arguments
what a character vector partially matching the names of the components listed in section ‘Value’, or NULL which lists all available capabilities.

Details
The capabilities have to be specified by the author of the graphics device, unless they can be deduced from missing hooks. Thus they will often by returned as NA, and may reflect the maximal capabilities of the underlying device where several output formats are supported by one device.

Most recent devices support semi-transparent colours provided the graphics format does (which PostScript does not). On the other hand, relatively few graphics formats support (fully or semi-) transparent backgrounds: generally the latter is found only in PDF and PNG plots.

Value
A named list with some or all of the following components, any of which may take value NA:

- semiTransparency logical: Does the device support semi-transparent colours?
- transparentBackground character: Does the device support (semi)-transparent backgrounds? Possible values are "no", "fully" (only full transparency) and "semi" (semi-transparent background colours are supported).
- rasterImage character: To what extent does the device support raster images as used by rasterImage and grid.raster? Possible values "no", "yes" and "non-missing" (support only for arrays without any missing values).
- capture logical: Does the current device support raster capture as used by grid.cap?
- locator logical: Does the current device support locator and identify?
- events character: Which events can be generated on this device? Currently this will be a subset of c("MouseDown", "MouseMove", "MouseUp", "Keybd"), but other events may be supported in the future.

See Also
See getGraphicsEvent for details on interactive events.

Examples
dev.capabilities()
dev.capture  

Capture device output as a raster image

Description

dev.capture captures the current contents of a graphics device as a raster (bitmap) image.

Usage

dev.capture(native = FALSE)

Arguments

native Logical. If FALSE the result is a matrix of R color names, if TRUE the output is returned as a nativeRaster object which is more efficient for plotting, but not portable.

Details

Not all devices support capture of the output as raster bitmaps. Typically, only image-based devices do and even not all of them.

Value

NULL if the device does not support capture, otherwise a matrix of color names (for native = FALSE) or a nativeRaster object (for native = TRUE).

dev.flush  

Hold or Flush Output on an On-Screen Graphics Device.

Description

This gives a way to hold/flush output on certain on-screen devices, and is ignored by other devices.

Usage

dev.hold(level = 1L)
dev.flush(level = 1L)

Arguments

level Integer >= 0. The amount by which to change the hold level. Negative values will be silently replaced by zero.
Details

Devices which implement this maintain a stack of hold levels: calling `dev.hold` increases the level and `dev.flush` decreases it. Calling `dev.hold` when the hold level is zero increases the hold level and inhibits graphics display. When calling `dev.flush` clears all pending holds the screen display is refreshed and normal operation is resumed.

This is implemented for the cairo-based X11 types with buffering. When the hold level is positive the ‘watch’ cursor is set on the device’s window.

It is available on the quartz device on macOS.

This is implemented for the windows device with buffering selected (the default). When the hold level is positive the ‘busy’ cursor is set on the device’s window.

Value

The current level after the change, invisibly. This is 0 on devices where hold levels are not supported.

---

dev.interactive

Is the Current Graphics Device Interactive?

Description

Test if the current graphics device (or that which would be opened) is interactive.

Usage

```r
dev.interactive(orNone = FALSE)
deviceIsInteractive(name = NULL)
```

Arguments

- `orNone` logical; if TRUE, the function also returns TRUE when `.Device == "null device"` and `getOption("device")` is among the known interactive devices.
- `name` one or more device names as a character vector, or NULL to give the existing list.

Details

The X11 (Unix), windows (Windows) and quartz (macOS, on-screen types only) are regarded as interactive, together with JavaGD (from the package of the same name) and CairoWin and CairoX11 (from package Cairo). Packages can add their devices to the list by calling `deviceIsInteractive`.

Value

`dev.interactive()` returns a logical, TRUE if and only if an interactive (screen) device is in use.

`deviceIsInteractive` returns the updated list of known interactive devices, invisibly unless `name = NULL`.

See Also

`Devices` for the available devices on your platform.
Examples

```r
dev.interactive()
print(deviceIsInteractive(NULL))
```

---

**dev.size**

*Find Size of Device Surface*

Description

Find the dimensions of the device surface of the current device.

Usage

```r
dev.size(units = c("in", "cm", "px"))
```

Arguments

- `units` the units in which to return the value – inches, cm, or pixels (device units).

Value

A two-element numeric vector giving width and height of the current device; a new device is opened if there is none, similarly to `dev.new()`.

See Also

The size information in inches can be obtained by `par("din")`, but this provides a way to access it independent of the graphics sub-system in use. Note that `par("din")` is only updated when a new plot is started, whereas `dev.size` tracks the size as an on-screen device is resized.

Examples

```r
dev.size("cm")
```

---

**dev2**

*Copy Graphics Between Multiple Devices*

Description

`dev.copy` copies the graphics contents of the current device to the device specified by `which` or to a new device which has been created by the function specified by `device` (it is an error to specify both `which` and `device`). (If recording is off on the current device, there are no contents to copy: this will result in no plot or an empty plot.) The device copied to becomes the current device.

`dev.print` copies the graphics contents of the current device to a new device which has been created by the function specified by `device` and then shuts the new device.

`dev.copy2eps` is similar to `dev.print` but produces an EPSF output file in portrait orientation (`horizontal = FALSE`). `dev.copy2pdf` is the analogue for PDF output.

`dev.control` allows the user to control the recording of graphics operations in a device. If `displaylist` is "inhibit" ("enable") then recording is turned off (on). It is only safe to change this at the beginning of a plot (just before or just after a new page). Initially recording is on for screen devices, and off for print devices.
Usage

dev.copy(device, ..., which = dev.next())
dev.print(device = postscript, ...)
dev.copy2eps(...)
dev.copy2pdf(..., out.type = "pdf")
dev.control(displaylist = c("inhibit", "enable"))

Arguments

device
A device function (e.g., x11, postscript,...)

... Arguments to the device function above: for dev.copy2eps arguments to postscript and for dev.copy2pdf, arguments to pdf. For dev.print, this includes which and by default any postscript arguments.

which
A device number specifying the device to copy to.

out.type
The name of the output device: can be "pdf", or "quartz" (some macOS builds) or "cairo" (Windows and some Unix-alikes, see cairo_pdf).

displaylist A character string: the only valid values are "inhibit" and "enable".

Details

Note that these functions copy the device region and not a plot: the background colour of the device surface is part of what is copied. Most screen devices default to a transparent background, which is probably not what is needed when copying to a device such as png.

For dev.copy2eps and dev.copy2pdf, width and height are taken from the current device unless otherwise specified. If just one of width and height is specified, the other is adjusted to preserve the aspect ratio of the device being copied. The default file name is Rplot.eps or Rplot.pdf, and can be overridden by specifying a file argument.

Copying to devices such as postscript and pdf which need font families pre-specified needs extra care – R is unaware of which families were used in a plot and so they will need to manually specified by the fonts argument passed as part of ... Similarly, if the device to be copied from was opened with a family argument, a suitable family argument will need to be included in ...

The default for dev.print is to produce and print a postscript copy. This will not work unless options("printcmd") is set suitably and you have a PostScript printing system: see postscript for how to set this up. Windows users may prefer to use dev.print(win.print).

dev.print is most useful for producing a postscript print (its default) when the following applies. Unless file is specified, the plot will be printed. Unless width, height and pointsize are specified the plot dimensions will be taken from the current device, shrunk if necessary to fit on the paper. (pointsize is rescaled if the plot is shrunk.) If horizontal is not specified and the plot can be printed at full size by switching its value this is done instead of shrinking the plot region.

If dev.print is used with a specified device (even postscript) it sets the width and height in the same way as dev.copy2eps. This will not be appropriate unless the device specifies dimensions in inches, in particular not for png, jpeg, tiff and bmp unless units = "inches" is specified.

Value

dev.copy returns the name and number of the device which has been copied to.

dev.print, dev.copy2eps and dev.copy2pdf return the name and number of the device which has been copied from.
Note

Most devices (including all screen devices) have a display list which records all of the graphics operations that occur in the device. dev.copy copies graphics contents by copying the display list from one device to another device. Also, automatic redrawing of graphics contents following the resizing of a device depends on the contents of the display list.

After the command dev.control("inhibit"). graphics operations are not recorded in the display list so that dev.copy and dev.print will not copy anything and the contents of a device will not be redrawn automatically if the device is resized.

The recording of graphics operations is relatively expensive in terms of memory so the command dev.control("inhibit") can be useful if memory usage is an issue.

See Also

dev.cur and other dev.xxx functions.

Examples

## Not run:
x11() # on a Unix-alike
plot(rnorm(10), main = "Plot 1")
dev.copy(device = x11)
mtext("Copy 1", 3)
dev.print(width = 6, height = 6, horizontal = FALSE) # prints it
dev.off(dev.prev())
dev.off()

## End(Not run)

---

**dev2bitmap**

*Graphics Device for Bitmap Files via Ghostscript*

Description

bitmap generates a graphics file. dev2bitmap copies the current graphics device to a file in a graphics format.

Usage

bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
units = "in", pointsize, taa = NA, gaa = NA, ...)

dev2bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
units = "in", pointsize, ..., 
method = c("postscript", "pdf"), taa = NA, gaa = NA)

Arguments

file The output file name, with an appropriate extension.
type The type of bitmap.
width, height Dimensions of the display region.
dev2bitmap

res Resolution, in dots per inch.
units The units in which height and width are given. Can be in (inches), px (pixels), cm or mm.
pointsize The pointsize to be used for text: defaults to something reasonable given the width and height.
... Other parameters passed to postscript or pdf.
method Should the plot be done by postscript or pdf?
taa, gaa Number of bits of antialiasing for text and for graphics respectively. Usually 4 (for best effect) or 2. Not supported on all types.

Details

dev2bitmap works by copying the current device to a postscript or pdf device, and post-processing the output file using ghostscript. bitmap works in the same way using a postscript device and post-processing the output as 'printing'.

You will need ghostscript: the full path to the executable can be set by the environment variable \texttt{R_GSCMD}. If this is unset, a GhostScript executable will be looked for by name on your path: on a Unix alike "gs" is used, and on Windows the setting of the environment variable \texttt{GSC} is used, otherwise commands "gswi64c.exe" then "gswin32c.exe" are tried.

The types available will depend on the version of ghostscript, but are likely to include "jpeg", "jpegcmky", "jpeggray", "tiffcrle", "tiffg3", "tiffg32d", "tiffg4", "tiffgray", "tiff1zw", "tiffpack", "tiff12nc", "tiff24nc", "tiff32nc" "png16", "png16m", "png256", "png48", "pngmono", "pnggray", "pngalpha", "bmp16", "bmp16m" "bmp256", "bmp32b", "bmpgray", "bmpmono".

The default type, "png16m", supports 24-bit colour and anti-aliasing. Type "png256" uses a palette of 256 colours and could give a more compact representation. Monochrome graphs can use "pngmono", or "pnggray" if anti-aliasing is desired. Plots with a transparent background and varying degrees of transparency should use "pngalpha".

Note that for a colour TIFF image you probably want "tiff24nc", which is 8-bit per channel RGB (the most common TIFF format). None of the listed TIFF types support transparency. "tiff32nc" uses 8-bit per channel CMYK, which printers might require.

For formats which contain a single image, a file specification like \texttt{Rplots\%03d.png} can be used: this is interpreted by Ghostscript.

For dev2bitmap if just one of width and height is specified, the other is chosen to preserve the aspect ratio of the device being copied. The main reason to prefer \texttt{method = "pdf"} over the default would be to allow semi-transparent colours to be used.

For graphics parameters such as "cra" that need to work in pixels, the default resolution of 72dpi is always used.

Value

None.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”. These devices follow the underlying device, so when viewed at the stated \texttt{res}:

- The default device size is 7 inches square.
• Font sizes are in big points.
• The default font family is (for the standard Ghostscript setup) URW Nimbus Sans.
• Line widths are as a multiple of 1/96 inch, with no minimum.
• Circle of any radius are allowed.
• Colours are interpreted by the viewing/printing application.

Note
Although using type = "pdfwrite" will work for simple plots, it is not recommended. Either use pdf to produce PDF directly, or call ps2pdf -dAutoRotatePages=/None on the output of postscript: that command is optimized to do the conversion to PDF in ways that these functions are not.

See Also
savePlot, which for windows and X11(type = "cairo") provides a simple way to record a PNG record of the current plot.
postscript, pdf, png, jpeg, tiff and bmp.
To display an array of data, see image.

---

**devAskNewPage**

**Prompt before New Page**

**Description**
This function can be used to control (for the current device) whether the user is prompted before starting a new page of output.

**Usage**

```r
devAskNewPage(ask = NULL)
```

**Arguments**

- `ask` NULL or a logical value. If TRUE, the user will in future be prompted before a new page of output is started.

**Details**
If the current device is the null device, this will open a graphics device.
The default argument just returns the current setting and does not change it.
The default value when a device is opened is taken from the setting of options("device.ask.default").
The precise circumstances when the user will be asked to confirm a new page depend on the graphics subsystem. Obviously this needs to be an interactive session. In addition ‘recording’ needs to be in operation, so only when the display list is enabled (see dev.control) which it usually is only on a screen device.
Devices

Value

The current prompt setting before any new setting is applied. Invisibly if ask is logical.

Devices

<table>
<thead>
<tr>
<th>List of Graphical Devices</th>
</tr>
</thead>
</table>

Description

The following graphics devices are currently available:

- **pdf** Write PDF graphics commands to a file
- **postscript** Writes PostScript graphics commands to a file
- **xfig** Device for XFIG graphics file format
- **bitmap** bitmap pseudo-device via Ghostscript (if available).
- **pictex** Writes TeX/PicTeX graphics commands to a file (of historical interest only)

The following devices will be functional if R was compiled to use them (they exist but will return with a warning on other systems):

- **X11** The graphics device for the X11 windowing system
- **cairo_pdf, cairo_ps** PDF and PostScript devices based on cairo graphics.
- **svg** SVG device based on cairo graphics.
- **png** PNG bitmap device
- **jpeg** JPEG bitmap device
- **bmp** BMP bitmap device
- **tiff** TIFF bitmap device
- **quartz** The graphics device for the macOS native Quartz 2d graphics system. (This is only functional on macOS where it can be used from the R.app GUI and from the command line: but it will display on the local screen even for a remote session.)

Details

If no device is open, using a high-level graphics function will cause a device to be opened. Which device is given by options("device") which is initially set as the most appropriate for each platform: a screen device for most interactive use and pdf (or the setting of R_DEFAULT_DEVICE) otherwise. The exception is interactive use under Unix if no screen device is known to be available, when pdf() is used.

It is possible for an R package to provide further graphics devices and several packages on CRAN do so. These include other devices outputting SVG and PGF/TiKZ (TeX-based graphics, see http://pgf.sourceforge.net/).
See Also

The individual help files for further information on any of the devices listed here: X11.options, quartz.options, ps.options and pdf.options for how to customize devices.
dev.interactive, dev.cur, dev.print, graphics.off, image, dev2bitmap.
capabilities to see if X11, jpeg png, tiff, quartz and the cairo-based devices are available.

Examples

```r
## Not run:
## open the default screen device on this platform if no device is
## open
if(dev.cur() == 1) dev.new()
## End(Not run)
```

embedFonts

Embed Fonts in PostScript and PDF

Description

Runs Ghostscript to process a PDF or PostScript file and embed all fonts in the file.

Usage

```r
embedFonts(file, format, outfile = file,
fontpaths = character(), options = character())
```

Arguments

- `file`: a character string giving the name of the original file.
- `format`: the format for the new file (with fonts embedded) given as the name of a ghostscript output device. If not specified, it is guessed from the suffix of `file`.
- `outfile`: the name of the new file (with fonts embedded).
- `fontpaths`: a character vector giving directories that Ghostscript will search for fonts.
- `options`: a character vector containing further options to Ghostscript.

Details

This function is not necessary if you just use the standard default fonts for PostScript and PDF output.

If you use a special font, this function is useful for embedding that font in your PostScript or PDF document so that it can be shared with others without them having to install your special font (provided the font licence allows this).

If the special font is not installed for Ghostscript, you will need to tell Ghostscript where the font is, using something like options="-sFONTPATH=path/to/font".

You will need ghostscript: the full path to the executable can be set by the environment variable R_GSCMD. If this is unset, a GhostScript executable will be looked for by name on your path: on a Unix alike "gs" is used, and on Windows the setting of the environment variable GSC is used, otherwise commands "gswi64c.exe" then "gswin32c.exe" are tried.
The format is by default "ps2write", when the original file has a .ps or .eps suffix, or "pdfwrite" when the original file has a .pdf suffix. For versions of Ghostscript before 9.10, format = "pswrite" or format = "epswrite" can be used: as from 9.14 format = "eps2write" is also available. If an invalid device is given, the error message will list the available devices.

Note that Ghostscript may do font substitution, so the font embedded may differ from that specified in the original file.

Some other options which can be useful (see your Ghostscript documentation) are `-dMaxSubsetPct=100`, `-dSubsetFonts=true` and `-dEmbedAllFonts=true`.

### Value

The shell command used to invoke Ghostscript is returned invisibly. This may be useful for debugging purposes as you can run the command by hand in a shell to look for problems.

### See Also

`postscriptFonts`, `Devices`.

---

### extendrange

*Extend a Numerical Range by a Small Percentage*

#### Description

Extends a numerical range by a small percentage, i.e., fraction, on both sides.

#### Usage

```r
extendrange(x, r = range(x, na.rm = TRUE), f = 0.05)
```

#### Arguments

- **x**: numeric vector; not used if `r` is specified.
- **r**: numeric vector of length 2; defaults to the `range` of `x`.
- **f**: number specifying the fraction by which the range should be extended.

#### Value

A numeric vector of length 2, `r + c(-f, f) * diff(r)`.

#### See Also

`range`, `pretty` which can be considered a sophisticated extension of `extendrange`. 
Examples

```r
x <- 1:5
(r <- range(x))  # 1 5
extendrange(x)   # 0.8 5.2
extendrange(x, f= 0.01) # 0.96 5.04
## Use 'r' if you have it already:
stopifnot(identical(extendrange(r = r),
                    extendrange(x)))
```

getGraphicsEvent

Wait for a mouse or keyboard event from a graphics window

Description

This function waits for input from a graphics window in the form of a mouse or keyboard event.

Usage

```r
getGraphicsEvent(prompt = "Waiting for input",
                  onMouseDown = NULL, onMouseMove = NULL,
                  onMouseUp = NULL, onKeybd = NULL,
                  onIdle = NULL,
                  consolePrompt = prompt)
setGraphicsEventHandlers(which = dev.cur(), ...)
getGraphicsEventEnv(which = dev.cur())
setGraphicsEventEnv(which = dev.cur(), env)
```

Arguments

- **prompt**: prompt to be displayed to the user in the graphics window
- **onMouseDown**: a function to respond to mouse clicks
- **onMouseMove**: a function to respond to mouse movement
- **onMouseUp**: a function to respond to mouse button releases
- **onKeybd**: a function to respond to key presses
- **onIdle**: a function to call when no events are pending
- **consolePrompt**: prompt to be displayed to the user in the console
- **which**: which graphics device does the call apply to?
- **...**: items including handlers to be placed in the event environment
- **env**: an environment to be used as the event environment

Details

These functions allow user input from some graphics devices (currently only the `windows()`, `X11(type = "Xlib")` and `X11(type = "cairo")` screen displays in base R). Event handlers may be installed to respond to events involving the mouse or keyboard.

The functions are related as follows. If any of the first six arguments to `getGraphicsEvent` are given, then it uses those in a call to `setGraphicsEventHandlers` to replace any existing handlers in
getGraphicsEvent

the current device. This is for compatibility with pre-2.12.0 R versions. The current normal way to set up event handlers is to set them using setGraphicsEventHandlers or setGraphicsEventEnv on one or more graphics devices, and then use getGraphicsEvent() with no arguments to retrieve event data. getGraphicsEventEnv() may be used to save the event environment for use later.

The names of the arguments in getGraphicsEvent are special. When handling events, the graphics system will look through the event environment for functions named onMouseDown, onMouseMove, onMouseUp, onKeybd, and onIdle, and use them as event handlers. It will use prompt for a label on the graphics device. Two other special names are which, which will identify the graphics device, and result, where the result of the last event handler will be stored before being returned by getGraphicsEvent().

The mouse event handlers should be functions with header function(buttons, x, y). The coordinates \( x \) and \( y \) will be passed to mouse event handlers in device independent coordinates (i.e., the lower left corner of the window is \((0,0)\), the upper right is \((1,1)\)). The buttons argument will be a vector listing the buttons that are pressed at the time of the event, with 0 for left, 1 for middle, and 2 for right.

The keyboard event handler should be a function with header function(key). A single element character vector will be passed to this handler, corresponding to the key press. Shift and other modifier keys will have been processed, so shift-a will be passed as "A". The following special keys may also be passed to the handler:

- Control keys, passed as "Ctrl-A", etc.
- Navigation keys, passed as one of "Left", "Up", "Right", "Down", "PgUp", "PgDn", "End", "Home"
- Edit keys, passed as one of "Ins", "Del"
- Function keys, passed as one of "F1", "F2", ...

The idle event handler onIdle should be a function with no arguments. If the function is undefined or NULL, then R will typically call a system function which (efficiently) waits for the next event to appear on a filehandle. Otherwise, the idle event handler will be called whenever the event queue of the graphics device was found to be empty, i.e. in an infinite loop. This feature is intended to allow animations to respond to user input, and could be CPU-intensive. Currently, onIdle is only implemented for X11() devices.

Note that calling Sys.sleep() is not recommended within an idle handler - Sys.sleep() removes pending graphics events in order to allow users to move, close, or resize windows while it is executing. Events such as mouse and keyboard events occurring during Sys.sleep() are lost, and currently do not trigger the event handlers registered via getGraphicsEvent or setGraphicsEventHandlers.

The event handlers are standard R functions, and will be executed as though called from the event environment.

In an interactive session, events will be processed until

- one of the event handlers returns a non-NULL value which will be returned as the value of getGraphicsEvent, or
- the user interrupts the function from the console.

Value

When run interactively, getGraphicsEvent returns a non-NULL value returned from one of the event handlers. In a non-interactive session, getGraphicsEvent will return NULL immediately. It will also return NULL if the user closes the last window that has graphics handlers.
getGraphicsEventEnv returns the current event environment for the graphics device, or NULL if none has been set.

setGraphicsEventEnv and setGraphicsEventHandlers return the previous event environment for the graphics device.

gray  

Gray Level Specification

Description
Create a vector of colors from a vector of gray levels.

Usage
gray(level, alpha = NULL)
grey(level, alpha = NULL)

Arguments
level  
a vector of desired gray levels between 0 and 1; zero indicates "black" and one indicates "white".
alpha  
the opacity, if specified.

Details
The values returned by gray can be used with a col= specification in graphics functions or in par.
grey is an alias for gray.

Value
A vector of colors of the same length as level.

See Also
rainbow, hsv, hcl, rgb.

Examples
gray(0:8 / 8)
Description

Create a vector of \( n \) gamma-corrected gray colors.

Usage

\[
gray.colors(n, start = 0.3, end = 0.9, gamma = 2.2, alpha = NULL) \\
grey.colors(n, start = 0.3, end = 0.9, gamma = 2.2, alpha = NULL)
\]

Arguments

- `n`: the number of gray colors (\( \geq 1 \)) to be in the palette.
- `start`: starting gray level in the palette (should be between 0 and 1 where zero indicates "black" and one indicates "white").
- `end`: ending gray level in the palette.
- `gamma`: the gamma correction.
- `alpha`: the opacity, is specified.

Details

The function `gray.colors` chooses a series of \( n \) gamma-corrected gray levels between `start` and `end`: \( \text{seq}(\text{start}^{\gamma}, \text{end}^{\gamma}, \text{length} = n)^{(1/\gamma)} \). The returned palette contains the corresponding gray colors. This palette is used in `barplot.default`.

`grey.colors` is an alias for `gray.colors`.

Value

A vector of \( n \) gray colors.

See Also

- `gray`, `rainbow`, `palette`.

Examples

```r
require(graphics)

pie(rep(1, 12), col = gray.colors(12))
barplot(1:12, col = gray.colors(12))
```
**grSoftVersion**

---

**Report Versions of Graphics Software**

**Description**

Report versions of third-party graphics software.

**Usage**

```r
grSoftVersion()
```

**Value**

A named character vector containing at least the element

- `cairo` the version of cairographics in use, or "" if cairographics is not available.

It may also contain the versions of third-party software used by the X11-based (not cairo-based) bitmap devices:

- `libpng` the version of libpng in use, or "" if not available.
- `jpeg` the version of the JPEG headers used for compilation, or "" if JPEG support was not compiled in.
- `libtiff` the version of libtiff in use, or "" if not available.

Unless otherwise stated the reported version is that of the (possibly dynamically-linked) library in use at runtime.

Note that libjpeg-turbo used on some Linux distributions reports its version as "6.2", the IJG version from which it forked.

**See Also**

- `extSoftVersion` for versions of non-graphics software.

**Examples**

```r
grSoftVersion()
```

---

**hcl**

---

**HCL Color Specification**

**Description**

Create a vector of colors from vectors specifying hue, chroma and luminance.

**Usage**

```r
hcl(h = 0, c = 35, l = 85, alpha, fixup = TRUE)
```
Arguments

- **h**: The hue of the color specified as an angle in the range \([0,360]\). 0 yields red, 120 yields green 240 yields blue, etc.
- **c**: The chroma of the color. The upper bound for chroma depends on hue and luminance.
- **l**: A value in the range \([0,100]\) giving the luminance of the colour. For a given combination of hue and chroma, only a subset of this range is possible.
- **alpha**: numeric vector of values in the range \([0,1]\) for alpha transparency channel (0 means transparent and 1 means opaque).
- **fixup**: a logical value which indicates whether the resulting RGB values should be corrected to ensure that a real color results. If `fixup` is `FALSE` RGB components lying outside the range \([0,1]\) will result in an `NA` value.

Details

This function corresponds to polar coordinates in the CIE-LUV color space. Steps of equal size in this space correspond to approximately equal perceptual changes in color. Thus, `hcl` can be thought of as a perceptually based version of `hsv`.

The function is primarily intended as a way of computing colors for filling areas in plots where area corresponds to a numerical value (pie charts, bar charts, mosaic plots, histograms, etc). Choosing colors which have equal chroma and luminance provides a way of minimising the irradiation illusion which would otherwise produce a misleading impression of how large the areas are.

The default values of chroma and luminance make it possible to generate a full range of hues and have a relatively pleasant pastel appearance.

The RGB values produced by this function correspond to the sRGB color space used on most PC computer displays. There are other packages which provide more general color space facilities.

Semi-transparent colors (\(0 < \text{alpha} < 1\)) are supported only on some devices: see `rgb`.

Value

A vector of character strings which can be used as color specifications by R graphics functions.

Missing or infinite values of any of `h`, `c`, `l` result in `NA`; such values of `alpha` are taken as 1 (opaque).

Note

At present there is no guarantee that the colours rendered by R graphics devices will correspond to their sRGB description. It is planned to adopt sRGB as the standard R color description in future.

demo(hclColors)
```

Hershey

Hershey Vector Fonts in R

Description

If the family graphical parameter (see `par`) has been set to one of the Hershey fonts (see ‘Details’) Hershey vector fonts are used to render text.
When using the `text` and `contour` functions Hershey fonts may be selected via the `vfont` argument, which is a character vector of length 2 (see `Details` for valid values). This allows Cyrillic to be selected, which is not available via the font families.

**Usage**

Hershey

**Details**

The Hershey fonts have two advantages:

1. Vector fonts describe each character in terms of a set of points; R renders the character by joining up the points with straight lines. This intimate knowledge of the outline of each character means that R can arbitrarily transform the characters, which can mean that the vector fonts look better for rotated text.

2. This implementation was adapted from the GNU libplot library which provides support for non-ASCII and non-English fonts. This means that it is possible, for example, to produce weird plotting symbols and Japanese characters.

**Drawback:**

You cannot use mathematical expressions (`plotmath`) with Hershey fonts.

The Hershey characters are organised into a set of fonts. A particular font is selected by specifying one of the following font families via `par(family)` and specifying the desired font face (plain, bold, italic, bold-italic) via `par(font)`.

```r
family   faces available
"HersheySerif"    plain, bold, italic, bold-italic
"HersheySans"    plain, bold, italic, bold-italic
"HersheyScript"  plain, bold
"HersheyGothicEnglish"  plain
"HersheyGothicGerman"  plain
"HersheyGothicItalian"  plain
"HersheySymbol"    plain, bold, italic, bold-italic
"HersheySansSymbol"  plain, italic
```

In the `vfont` specification for the `text` and `contour` functions, the Hershey font is specified by a typeface (e.g., serif or sans serif) and a fontindex or `style` (e.g., plain or italic). The first element of `vfont` specifies the typeface and the second element specifies the fontindex. The first table produced by `demo(Hershey)` shows the character a produced by each of the different fonts.

The available typeface and fontindex values are available as list components of the variable `Hershey`. The allowed pairs for (typeface, fontindex) are:

```r
serif    plain
serif    italic
serif    bold
serif    bold italic
serif    cyrillic
serif    oblique cyrillic
serif    EUC
sans serif    plain
```
and the indices of these are available as Hershey allowed.

**Escape sequences:** The string to be drawn can include escape sequences, which all begin with a ‘\’. When R encounters a ‘\’, rather than drawing the ‘\’, it treats the subsequent character(s) as a coded description of what to draw.

One useful escape sequence (in the current context) is of the form: ‘\123’. The three digits following the ‘\’ specify an octal code for a character. For example, the octal code for p is 160 so the strings "p" and "\160" are equivalent. This is useful for producing characters when there is not an appropriate key on your keyboard.

The other useful escape sequences all begin with ‘\’. These are described below. Remember that backslashes have to be doubled in R character strings, so they need to be entered with four backslashes.

**Symbols:** an entire string of Greek symbols can be produced by selecting the HersheySymbol or HersheySansSymbol family or the Serif Symbol or Sans Serif Symbol typeface. To allow Greek symbols to be embedded in a string which uses a non-symbol typeface, there are a set of symbol escape sequences of the form ‘\\ab’. For example, the escape sequence ‘\\*a’ produces a Greek alpha. The second table in demo(Hershey) shows all of the symbol escape sequences and the symbols that they produce.

**ISO Latin-1:** further escape sequences of the form ‘\\ab’ are provided for producing ISO Latin-1 characters. Another option is to use the appropriate octal code. The (non-ASCII) ISO Latin-1 characters are in the range 241...377. For example, ‘\366’ produces the character o with an umlaut. The third table in demo(Hershey) shows all of the ISO Latin-1 escape sequences. These characters can be used directly. (Characters not in Latin-1 are replaced by a dot.) Several characters are missing, c-cedilla has no cedilla and ‘sharp s’ (‘\U+00DF’, also known as ‘esszett’) is rendered as ss.

**Special Characters:** a set of characters are provided which do not fall into any standard font. These can only be accessed by escape sequence. For example, ‘\\LI’ produces the zodiac sign for Libra, and ‘\\JU’ produces the astronomical sign for Jupiter. The fourth table in demo(Hershey) shows all of the special character escape sequences.

**Cyrillic Characters:** cyrillic characters are implemented according to the K018-R encoding, and can be used directly in such a locale using the Serif typeface and Cyrillic (or Oblique Cyrillic) fontindex. Alternatively they can be specified via an octal code in the range 300 to 337 for lower case characters or 340 to 377 for upper case characters. The fifth table in demo(Hershey) shows the octal codes for the available Cyrillic characters.
Cyrillic has to be selected via a ("serif", fontindex) pair rather than via a font family.

**Japanese Characters:** 83 Hiragana, 86 Katakana, and 603 Kanji characters are implemented according to the EUC-JP (Extended Unix Code) encoding. Each character is identified by a unique hexadecimal code. The Hiragana characters are in the range 0x2421 to 0x2473, Katakana are in the range 0x2521 to 0x2576, and Kanji are (scattered about) in the range 0x3021 to 0x6d55.

When using the Serif typeface and EUC fontindex, these characters can be produced by a *pair* of octal codes. Given the hexadecimal code (e.g., 0x2421), take the first two digits and add 0x80 and do the same to the second two digits (e.g., 0x21 and 0x24 become 0xa4 and 0xa1), then convert both to octal (e.g., 0xa4 and 0xa1 become 244 and 241). For example, the first Hiragana character is produced by `'\244\241'`.

It is also possible to use the hexadecimal code directly. This works for all non-EUC fonts by specifying an escape sequence of the form `\#J1234`. For example, the first Hiragana character is produced by `\#J2421`.

The Kanji characters may be specified in a third way, using the so-called "Nelson Index", by specifying an escape sequence of the form `\#N1234`. For example, the (obsolete) Kanji for 'one' is produced by `\#N0001`.

demo(Japanese) shows the available Japanese characters.

**Raw Hershey Glyphs:** all of the characters in the Hershey fonts are stored in a large array. Some characters are not accessible in any of the Hershey fonts. These characters can only be accessed via an escape sequence of the form `\#H1234`. For example, the fleur-de-lys is produced by `\#H0746`. The sixth and seventh tables of demo(Hershey) shows all of the available raw glyphs.

---

**hsv**

**HSV Color Specification**

Create a vector of colors from vectors specifying hue, saturation and value.

**Usage**

```r
hsv(h = 1, s = 1, v = 1, alpha)
```
Japanese

743

Arguments
h,s,v

alpha

numeric vectors of values in the range [0, 1] for ‘hue’, ‘saturation’ and ‘value’
to be combined to form a vector of colors. Values in shorter arguments are
recycled.
numeric vector of values in the range [0, 1] for alpha transparency channel (0
means transparent and 1 means opaque).

Details
Semi-transparent colors (0 < alpha < 1) are supported only on some devices: see rgb.
Value
This function creates a vector of colors corresponding to the given values in HSV space. The values
returned by hsv can be used with a col= specification in graphics functions or in par.
See Also
hcl for a perceptually based version of hsv(), rgb and rgb2hsv for RGB to HSV conversion;
rainbow, gray.
Examples
require(graphics)
hsv(.5,.5,.5)
## Red tones:
n <- 20; y <- -sin(3*pi*((1:n)-1/2)/n)
op <- par(mar = rep(1.5, 4))
plot(y, axes = FALSE, frame.plot = TRUE,
xlab = "", ylab = "", pch = 21, cex = 30,
bg = rainbow(n, start = .85, end = .1),
main = "Red tones")
par(op)

Japanese

Japanese characters in R

Description
The implementation of Hershey vector fonts provides a large number of Japanese characters (Hiragana, Katakana, and Kanji).
Details
Without keyboard support for typing Japanese characters, the only way to produce these characters
is to use special escape sequences: see Hershey.
For example, the Hiragana character for the sound "ka" is produced by ‘\#J242b’ and the Katakana
character for this sound is produced by ‘\#J252b’. The Kanji ideograph for "one" is produced by
‘\#J306c’ or ‘\#N0001’.
The output from demo(Japanese) shows tables of the escape sequences for the available Japanese
characters.

make.rgb

Create colour spaces

Description
These functions specify colour spaces for use in convertColor.

Usage
make.rgb(red, green, blue, name = NULL, white = "D65",
          gamma = 2.2)

colorConverter(toXYZ, fromXYZ, name, white = NULL)

Arguments
red, green, blue  Chromaticity (xy or x\text{Y}) of RGB primaries
name              Name for the colour space
white             Character string specifying the reference white (see 'Details'.)
gamma             Display gamma (nonlinearity). A positive number or the string "sRGB"
fromXYZ           Function to convert from XYZ tristimulus coordinates to this space
toXYZ             Function to convert from this space to XYZ tristimulus coordinates.
Details

An RGB colour space is defined by the chromaticities of the red, green and blue primaries. These are given as vectors of length 2 or 3 in xyY coordinates (the Y component is not used and may be omitted). The chromaticities are defined relative to a reference white, which must be one of the CIE standard illuminants: "A", "B", "C", "D50", "D55", "D60", "E" (usually "D65").

The display gamma is most commonly 2.2, though 1.8 is used for Apple RGB. The sRGB standard specifies a more complicated function that is close to a gamma of 2.2; gamma = "sRGB" uses this function.

Colour spaces other than RGB can be specified directly by giving conversions to and from XYZ tristimulus coordinates. The functions should take two arguments. The first is a vector giving the coordinates for one colour. The second argument is the reference white. If a specific reference white is included in the definition of the colour space (as for the RGB spaces) this second argument should be ignored and may be ...

Value

An object of class `colorConverter`

`convertColor`

Examples

```r
(pal <- make.rgb(red = c(0.6400, 0.3300),
                 green = c(0.2900, 0.6000),
                 blue = c(0.1500, 0.0600),
                 name = "PAL/SECAM RGB"))

## converter for sRGB in #rrggbb format
hexcolor <- colorConverter(toXYZ = function(hex, ...) {
    rgb <- t(col2rgb(hex))/255
    colorspaces$sRGB$toXYZ(rgb, ...),
    fromXYZ = function(xyz, ...) {
        rgb <- colorspaces$sRGB$fromXYZ(xyz, ...)
        rgb <- round(rgb, 5)
        if (min(rgb) < 0 || max(rgb) > 1)
            as.character(NA)
        else rgb(rgb[1], rgb[2], rgb[3]),
        white = "D65", name = "#rrggbb")
}

(cols <- t(col2rgb(palette())))
zapsmall(luv <- convertColor(cols, from = "sRGB", to = "Luv", scale.in = 255))
(hex <- convertColor(luv, from = "Luv", to = hexcolor, scale.out = NULL))

## must make hex a matrix before using it
(cc <- round(convertColor(as.matrix(hex), from = hexcolor, to = "sRGB",
                          scale.in = NULL, scale.out = 255)))
stopifnot(cc == cols)
```
n2mfrow

Compute Default mfrow From Number of Plots

Description

Easy setup for plotting multiple figures (in a rectangular layout) on one page. This computes a sensible default for `par(mfrow)`.

Usage

```r
n2mfrow(nr.plots)
```

Arguments

- `nr.plots` integer; the number of plot figures you’ll want to draw.

Value

A length two integer vector `nr, nc` giving the number of rows and columns, fulfilling `nr >= nc >= 1` and `nr * nc >= nr.plots`.

Author(s)

Martin Maechler

See Also

`par`, `layout`.

Examples

```r
require(graphics)

n2mfrow(8) # 3 x 3

n <- 5 ; x <- seq(-2, 2, len = 51)
## suppose now that 'n' is not known (inside function)
op <- par(mfrow = n2mfrow(n))
for (j in 1:n)
  plot(x, x^j, main = substitute(x^ exp, list(exp = j)), type = "l",
col = "blue")
sapply(1:10, n2mfrow)
```
Compute the Number of Classes for a Histogram

Description

Compute the number of classes for a histogram.

Usage

nclass.Sturges(x)
nclass.scott(x)
nclass.FD(x)

Arguments

x a data vector.

Details

nclass.Sturges uses Sturges’ formula, implicitly basing bin sizes on the range of the data.
nclass.scott uses Scott’s choice for a normal distribution based on the estimate of the standard error, unless that is zero where it returns 1.
nclass.FD uses the Freedman-Diaconis choice based on the inter-quartile range (IQR(signif(x, 5))) unless that’s zero where it uses increasingly more extreme symmetric quantiles up to c(1,511)/512 and if that difference is still zero, reverts to using Scott’s choice.

Value

The suggested number of classes.

References

x <- rnorm(1000); xy <- cbind(x, 3*x + rnorm(1000))
plot (xy, lwd = 2,
main = "Alpha-Transparency Palette\n alpha = 0.3")
xy[,1] <- -xy[,1]
points(xy, col = 8, pch = 16, cex = 1.5)
palette("default")

<table>
<thead>
<tr>
<th>Palettes</th>
<th>Color Palettes</th>
</tr>
</thead>
</table>

Description

Create a vector of n contiguous colors.

Usage

rainbow(n, s = 1, v = 1, start = 0, end = max(1, n - 1)/n, alpha = 1)
heat.colors(n, alpha = 1)
terrain.colors(n, alpha = 1)
topo.colors(n, alpha = 1)
cm.colors(n, alpha = 1)

Arguments

n the number of colors (≥ 1) to be in the palette.
s, v the ‘saturation’ and ‘value’ to be used to complete the HSV color descriptions.
start the (corrected) hue in [0,1] at which the rainbow begins.
end the (corrected) hue in [0,1] at which the rainbow ends.
alpha the alpha transparency, a number in [0,1], see argument alpha in hsv.
Conceptually, all of these functions actually use (parts of) a line cut out of the 3-dimensional color space, parametrized by \( \text{hsv}(h, s, v) \), and hence equispaced hues in RGB space tend to cluster at the red, green and blue primaries.

Some applications such as contouring require a palette of colors which do not wrap around to give a final color close to the starting one.

With \text{rainbow}, the parameters \text{start} and \text{end} can be used to specify particular subranges of hues. The following values can be used when generating such a subrange: red = 0, yellow = \( \frac{1}{6} \), green = \( \frac{2}{6} \), cyan = \( \frac{3}{6} \), blue = \( \frac{4}{6} \) and magenta = \( \frac{5}{6} \).

\textbf{Value}

A character vector, \text{cv}, of color names. This can be used either to create a user–defined color palette for subsequent graphics by \text{palette(cv)}, a \text{col = specification in graphics functions or in par}.

\textbf{See Also}

\text{colors, palette, hsv, hcl, rgb, gray} and \text{col2rgb} for translating to RGB numbers.

\textbf{Examples}

\begin{verbatim}
require(graphics)
# A Color Wheel
pie(rep(1, 12), col = rainbow(12))

###------ Some palettes ---------
demo.pal <-
function(n, border = if (n < 32) "light gray" else NA,
main = paste("color palettes; n=", n),
ch.col = c("rainbow(n, start=.7, end=.1)", "heat.colors(n)",
"terrain.colors(n)", "topo.colors(n)",
"cm.colors(n)"),

{nt <- length(ch.col)
i <- 1:n; j <- n / nt; d <- j/6; dy <- 2*d
plot(i, i+d, type = "n", yaxt = "n", ylab = "", main = main)
for (k in 1:nt) {
  rect(i-.5, (k-1)*j+ dy, i+.4, k*j,
  col = eval(parse(text = ch.col[k])), border = border)
  text(2*j, k * j + dy/4, ch.col[k])
}
}

n <- if(.Device == "postscript") 64 else 16
# Since for screen, larger n may give color allocation problem
demo.pal(n)

\end{verbatim}
Usage

pdf(file = if(onefile) "Rplots.pdf" else "Rplot%03d.pdf",
width, height, onefile, family, title, fonts, version,
paper, encoding, bg, fg, pointsize, pagecentre, colormodel,
useDingbats, useKerning, fillOddEven, compress)

Arguments

file a character string giving the name of the file. If it is of the form "|cmd", the output is piped to the command given by cmd. If it is NULL, then no external file is created (effectively, no drawing occurs), but the device may still be queried (e.g., for size of text).

For use with onefile = FALSE give a C integer format such as "Rplot%03d.pdf" (the default in that case). (See postscript for further details.)

Tilde expansion (see path.expand) is done.

width, height the width and height of the graphics region in inches. The default values are 7.

onefile logical: if true (the default) allow multiple figures in one file. If false, generate a file with name containing the page number for each page. Defaults to TRUE, and forced to true if file is a pipe.

family the font family to be used, see postscript. Defaults to "Helvetica".

title title string to embed as the '/Title' field in the file. Defaults to "R Graphics Output".

fonts a character vector specifying R graphics font family names for additional fonts which will be included in the PDF file. Defaults to NULL.

version a string describing the PDF version that will be required to view the output. This is a minimum, and will be increased (with a warning) if necessary. Defaults to "1.4", but see 'Details'.

paper the target paper size. The choices are "a4", "letter", "legal" (or "us") and "executive" (and these can be capitalized), or "a4r" and "USr" for rotated ('landscape'). The default is "special", which means that the width and height specify the paper size. A further choice is "default"; if this is selected, the papersize is taken from the option "papersize" if that is set and as "a4" if it is unset or empty. Defaults to "special".

encoding the name of an encoding file. See postscript for details. Defaults to "default".

bg the initial background color to be used. Defaults to "transparent".

fg the initial foreground color to be used. Defaults to "black".

pointsize the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points. Defaults to 12.

pagecentre logical: should the device region be centred on the page? – is only relevant for paper != "special". Defaults to TRUE.

colormodel a character string describing the color model: currently allowed values are "srgb", "gray" (or "grey") and "cmyk". Defaults to "srgb". See section 'Color models'.

useDingbats logical. Should small circles be rendered via the Dingbats font? Defaults to TRUE, which produces smaller and better output. Setting this to FALSE can work
around font display problems in broken PDF viewers: although this font is one of the 14 guaranteed to be available in all PDF viewers, that guarantee is not always honoured. See the ‘Note’ for a possible fix for some viewers.

useKerning logical. Should kerning corrections be included in setting text and calculating string widths? Defaults to TRUE.

fillOddEven logical controlling the polygon fill mode: see polygon for details. Defaults to FALSE.

compress logical. Should PDF streams be generated with Flate compression? Defaults to TRUE.

Details

All arguments except file default to values given by pdf.options(). The ultimate defaults are quoted in the arguments section.

pdf() opens the file file and the PDF commands needed to plot any graphics requested are sent to that file.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument the page number. The default gives files ‘Rplot001.pdf’, ‘Rplot099.pdf’, ‘Rplot100.pdf’, ....

The family argument can be used to specify a PDF-specific font family as the initial/default font for the device. If additional font families are to be used they should be included in the fonts argument.

If a device-independent R graphics font family is specified (e.g., via par(family = ) in the graphics package), the PDF device makes use of the PostScript font mappings to convert the R graphics font family to a PDF-specific font family description. (See the documentation for pdfFonts.)

This device does not embed fonts in the PDF file, so it is only straightforward to use mappings to the font families that can be assumed to be available in any PDF viewer: “Times” (equivalently “serif”), “Helvetica” (equivalently “sans”) and “Courier” (equivalently “mono”). Other families may be specified, but it is the user’s responsibility to ensure that these fonts are available on the system and third-party software (e.g., Ghostscript) may be required to embed the fonts so that the PDF can be included in other documents (e.g., LaTeX): see embedFonts. The URW-based families described for postscript can be used with viewers set up to use URW fonts, which is usual with those based on xpdf or Ghostscript. Since embedFonts makes use of Ghostscript, it should be able to embed the URW-based families for use with other viewers.

See postscript for details of encodings, as the internal code is shared between the drivers. The native PDF encoding is given in file ‘PDFDoc.enc’.

The PDF produced is fairly simple, with each page being represented as a single stream (by default compressed and possibly with references to raster images). The R graphics model does not distinguish graphics objects at the level of the driver interface.

The version argument declares the version of PDF that gets produced. The version must be at least 1.2 when compression is used, 1.4 for semi-transparent output to be understood, and at least 1.3 if CID fonts are to be used: if any of these features are used the version number will be increased (with a warning). (PDF 1.4 was first supported by Acrobat 5 in 2001; it is very unlikely not to be supported in a current viewer.)

Line widths as controlled by par(lwd = ) are in multiples of 1/96 inch. Multiples less than 1 are allowed. pch = "." with cex = 1 corresponds to a square of side 1/72 inch, which is also the ‘pixel’ size assumed for graphics parameters such as "cra".

The paper argument sets the ‘/MediaBox’ entry in the file, which defaults to width by height. If it is set to something other than “special”, a device region of the specified size is (by default) centred on the rectangle given by the paper size: if either width or height is less than 0.1 or too large to
give a total margin of 0.5 inch, it is reset to the corresponding paper dimension minus 0.5. Thus if you want the default behaviour of `postscript` use `pdf(paper = "a4r", width = 0, height = 0)` to centre the device region on a landscape A4 page with 0.25 inch margins.

When the background colour is fully transparent (as is the initial default value), the PDF produced does not paint the background. Most PDF viewers will use a white canvas so the visual effect is if the background were white. This will not be the case when printing onto coloured paper, though.

**Color models**

The default color model ("srgb") is sRGB. Model "gray" (or "grey") maps sRGB colors to greyscale using perceived luminosity (biased towards green). “cmyk” outputs in CMYK colorspace. The simplest possible conversion from sRGB to CMYK is used (https://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK), and raster images are output in RGB.

Also available for backwards compatibility is model "rgb" which uses uncalibrated RGB and corresponds to the model used with that name in R prior to 2.13.0. Some viewers may render some plots in that colorspace faster than in sRGB, and the plot files will be smaller.

**Conventions**

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are as a multiple of 1/96 inch, with a minimum of 0.01 enforced.
- Circles of any radius are allowed. Unless `useDingbats = FALSE` opaque circles of less than 10 big points radius are rendered using char 108 in the Dingbats font: all semi-transparent and larger circles using a Bézier curve for each quadrant.
- Colours are by default specified as sRGB.

At very small line widths, the line type may be forced to solid.

**Printing**

Except on Windows it is possible to print directly from pdf by something like (this is appropriate for a CUPS printing system):

```
pdf("|lp -o landscape", paper = "a4r")
```

This forces `onfie = TRUE`.

**Note**

If you see problems with PDF output, do remember that the problem is much more likely to be in your viewer than in R. Try another viewer if possible. Symptoms for which the viewer has been at fault are apparent grids on image plots (turn off graphics anti-aliasing in your viewer if you can) and missing or incorrect glyphs in text (viewers silently doing font substitution).

Unfortunately the default viewers on most Linux and macOS systems have these problems, and no obvious way to turn off graphics anti-aliasing.
Acrobat Reader does not use the fonts specified but rather emulates them from multiple-master fonts. This can be seen in imprecise centering of characters, for example the multiply and divide signs in Helvetica. This can be circumvented by embedding fonts where possible. Most other viewers substitute fonts, e.g. URW fonts for the standard Helvetica and Times fonts, and these too often have different font metrics from the true fonts.

Acrobat Reader can be extended by ‘font packs’, and these will be needed for the full use of encodings other than Latin-1 (although they may be offered for download as needed).

On some systems the default plotting character \( pch = 1 \) was displayed in some PDF viewers incorrectly as a “q” character. (These seem to be viewers based on the ‘poppler’ PDF rendering library). This may be due to incorrect or incomplete mapping of font names to those used by the system. Adding the following lines to ‘~/.fonts.conf’ or ‘/etc/fonts/local.conf’ may circumvent this problem, although this has largely been corrected on the affected systems.

```
<fontconfig>
<alias binding="same">
  <family>ZapfDingbats</family>
  <accept><family>Dingbats</family></accept>
</alias>
</fontconfig>
```

Some further workarounds for problems with symbol fonts on viewers using ‘fontconfig’ are given in the ‘Cairo Fonts’ section of the help for \texttt{X11}.

There is a different font bug in the pdf.js viewer included in Firefox 19 and later: that maps Dingbats to the Symbol font and so displays symbols such \( pch = 1 \) as lambda.

\textbf{See Also}

\texttt{pdfFonts, pdf.options, embedFonts, Devices, postscript. cairo_pdf} and (on macOS only) \texttt{quartz} for other devices that can produce PDF.

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in

\textbf{Examples}

```r
## Test function for encodings
TestChars <- function(encoding = "ISO8859-1", ...) {
  pdf(encoding = encoding, ...)
  par(pty = "s")
  plot(c(-1,16), c(-1,16), type = "n", xlab = "", ylab = "",
       xaxs = "i", yaxs = "i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty = 1)
  for(i in c(32:255)) {
    x <- i %% 16
    y <- i %/% 16
    points(x, y, pch = i)
  }
  dev.off()
}
## there will be many warnings.
```
pdf.options

## this does not view properly in older viewers.
TestChars("ISOLatin2", family = "URWHelvetica")
## works well for viewing in gs-based viewers, and often in xpdf.

### pdf.options

**Auxiliary Function to Set/View Defaults for Arguments of pdf**

**Description**

The auxiliary function `pdf.options` can be used to set or view (if called without arguments) the default values for some of the arguments to `pdf`

`pdf.options` needs to be called before calling `pdf`, and the default values it sets can be overridden by supplying arguments to `pdf`.

**Usage**

```r
pdf.options(..., reset = FALSE)
```

**Arguments**

- `...`: arguments `width`, `height`, `oneline`, `family`, `title`, `fonts`, `paper`, `encoding`, `pointsize`, `bg`, `fg`, `pagecentre`, `useDingbats`, `colormodel`, `fillOddEven` can be supplied.
- `reset`: logical: should the defaults be reset to their ‘factory-fresh’ values?

**Details**

If both `reset = TRUE` and `...` are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

**Value**

A named list of all the defaults. If any arguments are supplied the return values are the old values and the result has the visibility flag turned off.

**See Also**

`pdf`, `ps.options`

**Examples**

```r
pdf.options(bg = "pink")
utils::str(pdf.options())
pdf.options(reset = TRUE) # back to factory-fresh
```
Description

This function produces simple graphics suitable for inclusion in TeX and LaTeX documents. It dates from the very early days of R and is for historical interest only.

Usage

```r
pictex(file = "Rplots.tex", width = 5, height = 4, debug = FALSE,
        bg = "white", fg = "black")
```

Arguments

- **file** the file where output will appear.
- **width** The width of the plot in inches.
- **height** the height of the plot in inches.
- **debug** should debugging information be printed.
- **bg** the background color for the plot. Ignored.
- **fg** the foreground color for the plot. Ignored.

Details

This driver is much more basic than the other graphics drivers included in R. It does not have any font metric information, so the use of `plotmath` is not supported.

Line widths are ignored except when setting the spacing of line textures. `pch = "."` corresponds to a square of side 1pt.

This device does not support colour (nor does the PicTeX package), and all colour settings are ignored.

Note that text is recorded in the file as-is, so annotations involving TeX special characters (such as ampersand and underscore) need to be quoted as they would be when entering TeX.

Multiple plots will be placed as separate environments in the output file.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 5 inches by 4 inches.
- There is no `pointsize` argument: the default size is interpreted as 10 point.
- The only font family is `cmss10`.
- Line widths are only used when setting the spacing on line textures.
- Circle of any radius are allowed.
- Colour is not supported.
Author(s)

This driver was provided around 1996–7 by Valerio Aimale of the Department of Internal Medicine, University of Genoa, Italy.

*plotmath*  
*Mathematical Annotation in R*
Description

If the text argument to one of the text-drawing functions (text, mtext, axis, legend) in R is an expression, the argument is interpreted as a mathematical expression and the output will be formatted according to TeX-like rules. Expressions can also be used for titles, subtitles and x- and y-axis labels (but not for axis labels on persp plots).

In most cases other language objects (names and calls, including formulas) are coerced to expressions and so can also be used.

Details

A mathematical expression must obey the normal rules of syntax for any R expression, but it is interpreted according to very different rules than for normal R expressions.

It is possible to produce many different mathematical symbols, generate sub- or superscripts, produce fractions, etc.

The output from demo(plotmath) includes several tables which show the available features. In these tables, the columns of grey text show sample R expressions, and the columns of black text show the resulting output.

The available features are also described in the tables below:

<table>

x + over(1, phantom(0)) leave vertical gap for "0" (don’t draw)
frac(x, y) x over y
over(x, y) x over y
atop(x, y) x over y (no horizontal bar)
sum(x[i], i=1, n) sum x[i] for i equals 1 to n
prod(plain(P)(x==x), x) product of P(X=x) for all values of x
integral(f(x)*dx, a, b) definite integral of f(x) wrt x
union(A[i], i==1, n)  union of A[i] for i equals 1 to n
intersect(A[i], i==1, n) intersection of A[i]
lim(f(x), x %->% 0) limit of f(x) as x tends to 0
min(g(x), x > 0) minimum of g(x) for x greater than 0
inf(S) infimum of S
sup(S) supremum of S
x^y + z normal operator precedence
x^(y + z) visible grouping of operands
x^{y + z} invisible grouping of operands
group("\( \),list(a, b),\"]") specify left and right delimiters
bgroupl("\( \),atop(x,y),\") use scalable delimiters
group(lceil, x, rceil) special delimiters
group(lfloor, x, rfloor) special delimiters

The supported ‘scalable delimiters’ are | ([ {,.lceil,lfloor and their right-hand versions. "." is equivalent to ".": the corresponding delimiter will be omitted. Delimiter || is supported but has the same effect as |.

The symbol font uses Adobe Symbol encoding so, for example, a lower case mu can be obtained either by the special symbol \mu or by symbol("m"). This provides access to symbols that have no special symbol name, for example, the universal, or forall, symbol is symbol("\forall"). To see what symbols are available in this way use TestChars(font=5) as given in the examples for points: some are only available on some devices.

Note to TeX users: TeX’s ‘\Upsilon’ is Upsilon1, TeX’s ‘\varepsilon’ is close to epsilon, and there is no equivalent of TeX’s ‘\epsilon’. TeX’s ‘\varpi’ is close to omega1. vartheta, varphi and varsigma are allowed as synonyms for thetal, phi1 and sigma1.

sigma1 is also known as stigma, its Unicode name.

Control characters (e.g., ‘\n’) are not interpreted in character strings in plotmath, unlike normal plotting.

The fonts used are taken from the current font family, and so can be set by par(family=) in base graphics, and gpar(fontfamily=) in package grid.

Note that bold, italic and bolditalic do not apply to symbols, and hence not to the Greek symbols such as \mu which are displayed in the symbol font. They also do not apply to numeric constants.

Other symbols

On many OSes and some graphics devices many other symbols are available as part of the standard text font, and all of the symbols in the Adobe Symbol encoding are in principle available via changing the font face or (see ‘Details’) plotmath: see the examples section of points for a function to display them. (‘In principle’ because some of the glyphs are missing from some implementations of the symbol font.) Unfortunately, postscript and pdf have support for little more than European (not Greek) and CJK characters and the Adobe Symbol encoding (and in a few fonts, also Cyrillic characters).

In a UTF-8 locale any Unicode character can be entered, perhaps as a ‘\uxxxx’ or ‘\Uxxxxxxxx’ escape sequence, but the issue is whether the graphics device is able to display the character. The widest range of characters is likely to be available in the X11 device using cairo: see its help page for how installing additional fonts can help. This can often be used to display Greek letters in bold or italic.
In non-UTF-8 locales there is normally no support for symbols not in the languages for which the current encoding was intended.

### PNG, BMP, JPEG and TIFF graphics devices

#### Description

Graphics devices for BMP, JPEG, PNG and TIFF format bitmap files.

#### Usage

**BMP**

```
bmp(filename = "Rplot%03d.bmp",
     width = 480, height = 480, units = "px", pointsize = 12,
     bg = "white", res = NA,...,
     type = c("cairo", "Xlib", "quartz"), antialias)
```

**JPEG**

```
jpeg(filename = "Rplot%03d.jpeg",
      width = 480, height = 480, units = "px", pointsize = 12,
      quality = 75,
      bg = "white", res = NA,...,
      type = c("cairo", "Xlib", "quartz"), antialias)
```

**PNG**

```
png(filename = "Rplot%03d.png",
      width = 480, height = 480, units = "px", pointsize = 12,
      bg = "white", res = NA,...,
      type = c("cairo", "cairo-png", "Xlib", "quartz"), antialias)
```

**TIFF**

```
tiff(filename = "Rplot%03d.tiff",
      width = 480, height = 480, units = "px", pointsize = 12,
      bg = "white", res = NA,...,
      type = c("cairo", "Xlib", "quartz"), antialias)
```
width = 480, height = 480, units = "px", pointsize = 12,
compression = c("none", "rle", "lzw", "jpeg", "zip", "lzw+p", "zip+p"),
bg = "white", res = NA, ....,
type = c("cairo", "Xlib", "quartz"), antialias)

Arguments

filename the name of the output file. The page number is substituted if a C integer format
is included in the character string, as in the default. (The result must be less than
PATH_MAX characters long, and may be truncated if not. See postscript for
further details.) Tilde expansion is performed where supported by the platform.

width the width of the device.

height the height of the device.

units The units in which height and width are given. Can be px (pixels, the default),
in (inches), cm or mm.

pointsize the default pointsize of plotted text, interpreted as big points (1/72 inch) at res
ppi.

bg the initial background colour: can be overridden by setting par("bg").

quality the ‘quality’ of the JPEG image, as a percentage. Smaller values will give more
compression but also more degradation of the image.

compression the type of compression to be used. Ignored for type = "quartz".

res The nominal resolution in ppi which will be recorded in the bitmap file, if a
positive integer. Also used for units other than the default, and to convert
points to pixels.

... for type = "Xlib" only, additional arguments to the underlying X11 device
such as fonts or family.

For types "cairo" and "quartz", the family argument can be supplied. See
the ‘Cairo fonts’ section in the help for
X11.

type character string, one of "Xlib" or "quartz" (some macOS builds) or "cairo".
The latter will only be available if the system was compiled with sup-
port for cairo – otherwise "Xlib" will be used. The default is set by
getOption("bitmapType") – the ‘out of the box’ default is "quartz" or
"cairo" where available, otherwise "Xlib".

antialias for type = "cairo", giving the type of anti-aliasing (if any) to be used for fonts
and lines (but not fills). See X11. The default is set by X11.options. Also for
type = "quartz", where antialiasing is used unless antialias = "none".

Details

Plots in PNG and JPEG format can easily be converted to many other bitmap formats, and both can
be displayed in modern web browsers. The PNG format is lossless and is best for line diagrams and
blocks of colour. The JPEG format is lossy, but may be useful for image plots, for example. BMP
is a standard format on Windows. TIFF is a meta-format: the default format written by tiff is
lossless and stores RGB (and alpha where appropriate) values uncompressed—such files are widely
accepted, which is their main virtue over PNG.

png supports transparent backgrounds: use bg = "transparent". (Not all PNG viewers render
files with transparency correctly.) When transparency is in use in the type = "Xlib" variant a
very light grey is used as the background and so appears as transparent if used in the plot. This
allows opaque white to be used, as in the example. The type = "cairo", type = "cairo-png"
and type = "quartz" variants allow semi-transparent colours, including on a transparent or semi-transparent background.

*tiff* with types "cairo" and "quartz" supports semi-transparent colours, including on a transparent or semi-transparent background. Compression type "zip" is 'deflate (Adobe-style)'. Compression types "1zw+p" and "zip+p" use horizontal differencing ('differencing predictor', section 14 of the TIFF specification) in combination with the compression method, which is effective for continuous-tone images, especially colour ones.

*R* can be compiled without support for some or all of the types for each of these devices: this will be reported if you attempt to use them on a system where they are not supported. For type = "Xlib" they may not be usable unless the X11 display is available to the owner of the R process. type = "cairo" requires cairo 1.2 or later. type = "quartz" uses the Quartz device and so is only available where that is (on some macOS builds: see `capabilities("aqua")`).

By default no resolution is recorded in the file, except for BMP. Viewers will often assume a nominal resolution of 72 ppi when none is recorded. As resolutions in PNG files are recorded in pixels/metre, the reported ppi value will be changed slightly.

For graphics parameters that make use of dimensions in inches (including font sizes in points) the resolution used is `res` (or 72 ppi if unset).

*png* will normally use a palette if there are less than 256 colours on the page, and record a 24-bit RGB file otherwise (or a 32-bit ARGB file if type = "cairo" and non-opaque colours are used). However, type = "cairo-png" uses cairographics' PNG backend which will never use a palette and normally creates a larger 32-bit ARGB file—this may work better for specialist uses with semi-transparent colours.

Quartz-produced PNG and TIFF plots with a transparent background are recorded with a dark grey matte which will show up in some viewers, including Preview on macOS.

Unknown resolutions in BMP files are recorded as 72 ppi.

### Value

A plot device is opened: nothing is returned to the R interpreter.

### Warnings

Note that by default the width and height values are in pixels not inches. A warning will be issued if both are less than 20.

If you plot more than one page on one of these devices and do not include something like `%d` for the sequence number in `file`, the file will contain the last page plotted.

### Differences between OSes

These functions are interfaces to three or more different underlying devices.

- On Windows, devices based on plotting to a hidden screen using Windows’ GDI calls.
- On platforms with support for X11, plotting to a hidden X11 display.
- On macOS when working at the console and when R is compiled with suitable support, using Apple’s Quartz plotting system.
- Where support has been compiled in for cairographics, plotting on cairo surfaces. This may use the native platform support for fonts, or it may use fontconfig to support a wide range of font formats.
Inevitably there will be differences between the options supported and output produced. Perhaps the most important are support for antialiased fonts and semi-transparent colours: the best results are likely to be obtained with the cairo- or Quartz-based devices where available. The default extensions are `.jpg` and `.tif` on Windows, and `.jpeg` and `.tiff` elsewhere.

**Conventions**

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is in pixels.
- Font sizes are in big points interpreted at res ppi.
- The default font family is Helvetica.
- Line widths in 1/96 inch (interpreted at res ppi), minimum one pixel for type = “Xlib”, 0.01 for type = “cairo”.
- For type = "Xlib" circle radii are in pixels with minimum one.
- Colours are interpreted by the viewing application.

For type = “quartz” see the help for quartz.

**Note**

For type = “Xlib” these devices are based on the X11 device. The colour model used will be that set up by X11.options at the time the first Xlib-based devices was opened (or the first after all such devices have been closed).

Devices, dev.print

capabilities to see if these devices are supported by this build of R, and if type = “cairo” is supported.

bitmap provides an alternative way to generate plots in many bitmap formats that does not depend on accessing the X11 display but does depend on having GhostScript installed.

**Examples**

```r
## these examples will work only if the devices are available
## and cairo or an X11 display or a macOS display is available.

## copy current plot to a (large) PNG file
## Not run: dev.print(png, file = "myplot.png", width = 1024, height = 768)
```
postscript

PostScript Graphics

Description

postscript starts the graphics device driver for producing PostScript graphics.

Usage

postscript(file = if(onefile) "Rplots.ps" else "Rplot%03d.ps",
          onefile, family, title, fonts, encoding, bg, fg,
          width, height, horizontal, pointsize,
          paper, pagecentre, print.it, command,
          colormodel, useKerning, fillOddEven)

Arguments

file a character string giving the name of the file. If it is ",", the output is piped to the
      command given by the argument command. If it is of the form "|cmd", the
      output is piped to the command given by cmd.

For use with onefile = FALSE give a printf format such as "Rplot%03d.ps"
      (the default in that case). The string should not otherwise contain a %: if it is re-
      ally necessary, use % in the string for % in the file name. A single integer format
      matching the regular expression "%\[#0 +=-]*[0-9.]*[diouxX]" is allowed.

Tilde expansion (see path.expand) is done.

onefile logical: if true (the default) allow multiple figures in one file. If false, generate
      a file name containing the page number for each page and use an EPSF header and
      no DocumentMedia comment. Defaults to TRUE.

family the initial font family to be used, normally as a character string. See the section
      'Families'. Defaults to "Helvetica".

title title string to embed as the Title comment in the file. Defaults to "R Graphics Output".

fonts a character vector specifying additional R graphics font family names for font
      families whose declarations will be included in the PostScript file and are available
      for use with the device. See 'Families' below. Defaults to NULL.

encoding the name of an encoding file. Defaults to "default". The latter is interpreted as
      "ISOLatin1.enc" unless the locale is recognized as corresponding to a
      language using ISO 8859-\{2,5,7,13,15\} or KOI8-\{R,U\}. The file is looked for
      in the 'enc' directory of package grDevices if the path does not contain a path
      separator. An extension ".enc" can be omitted.
postscript opens the file file and the PostScript commands needed to plot any graphics requested are written to that file. This file can then be printed on a suitable device to obtain hard copy.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument the page number. The default gives files 'Rplot001.ps', 'Rplot999.ps', 'Rplot1000.ps', .... The postscript produced for a single R plot is EPS (Encapsulated PostScript) compatible, and can be included into other documents, e.g., into LaTeX, using \includegraphics{<filename>}. For use in this way you will probably want to use setEPS() to set the defaults as horizontal = FALSE, onefile = FALSE, paper = "special". Note that the bounding box is for the device region: if you find the white space around the plot region excessive, reduce the margins of the figure region via par(mar = ).

Most of the PostScript prologue used is taken from the R character vector .ps.prolog. This is marked in the output, and can be changed by changing that vector. (This is only advisable for PostScript experts: the standard version is in namespace:grDevices.)

A PostScript device has a default family, which can be set by the user via family. If other font families are to be used when drawing to the PostScript device, these must be declared when the
device is created via fonts; the font family names for this argument are \texttt{R} graphics font family names (see the documentation for \texttt{postscriptFonts}).

Line widths as controlled by \texttt{par(lwd = )} are in multiples of 1/96 inch: multiples less than 1 are allowed. \texttt{pch = "."} with \texttt{cex = 1} corresponds to a square of side 1/72 inch, which is also the ‘pixel’ size assumed for graphics parameters such as “cra”.

When the background colour is fully transparent (as is the initial default value), the PostScript produced does not paint the background. Almost all PostScript viewers will use a white canvas so the visual effect is if the background were white. This will not be the case when printing onto coloured paper, though.

**Families**

Font families are collections of fonts covering the five font faces, (conventionally plain, bold, italic, bold-italic and symbol) selected by the graphics parameter \texttt{par(font = )} or the grid parameter \texttt{gpar(fontface = )}. Font families can be specified either as an an initial/default font family for the device via the family argument or after the device is opened by the graphics parameter \texttt{par(family = )} or the grid parameter \texttt{gpar(fontfamily = )}. Families which will be used in addition to the initial family must be specified in the \texttt{fonts} argument when the device is opened.

Font families are declared via a call to \texttt{postscriptFonts}.

The argument \texttt{family} specifies the initial/default font family to be used. In normal use it is one of "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times", and refers to the standard Adobe PostScript fonts families of those names which are included (or cloned) in all common PostScript devices.

Many PostScript emulators (including those based on ghostscript) use the URW equivalents of these fonts, which are "URWGothic", "URWBookman", "NimbusMon", "NimbusSan", "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" respectively. If your PostScript device is using URW fonts, you will obtain access to more characters and more appropriate metrics by using these names. To make these easier to remember, "URWHelvetica" == "NimbusSan" and "URWTimes" == "NimbusRom" are also supported.

Another type of family makes use of CID-keyed fonts for East Asian languages – see \texttt{postscriptFonts}.

The \texttt{family} argument is normally a character string naming a font family, but family objects generated by \texttt{Type1Font} and \texttt{CIDFont} are also accepted. For compatibility with earlier versions of \texttt{R}, the initial family can also be specified as a vector of four or five afm files.

Note that \texttt{R} does not embed the font(s) used in the PostScript output: see \texttt{embedFonts} for a utility to help do so.

Viewers and embedding applications frequently substitute fonts for those specified in the family, and the substitute will often have slightly different font metrics. \texttt{useKerning = TRUE} spaces the letters in the string using kerning corrections for the intended family: this may look uglier than \texttt{useKerning = FALSE}.

**Encodings**

Encodings describe which glyphs are used to display the character codes (in the range 0–255). Most commonly \texttt{R} uses ISOLatin1 encoding, and the examples for \texttt{text} are in that encoding. However, the encoding used on machines running \texttt{R} may well be different, and by using the encoding argument the glyphs can be matched to encoding in use. This suffices for European and Cyrillic languages, but not for East Asian languages. For the latter, composite CID fonts are used. These fonts are useful for other languages: for example they may contain Greek glyphs. (The rest of this section applies only when CID fonts are not used.)
None of this will matter if only ASCII characters (codes 32–126) are used as all the encodings (except "TeXtext") agree over that range. Some encodings are supersets of ISOLatin1, too. However, if accented and special characters do not come out as you expect, you may need to change the encoding. Some other encodings are supplied with R: "WinAnsi.enc" and "MacRoman.enc" correspond to the encodings normally used on Windows and Classic Mac OS (at least by Adobe), and "PDFDoc.enc" is the first 256 characters of the Unicode encoding, the standard for PDF. There are also encodings "ISOLatin2.enc", "CP1250.enc", "ISOLatin7.enc" (ISO 8859-13), "CP1257.enc", and "ISOLatin9.enc" (ISO 8859-15), "Cyrillic.enc" (ISO 8859-5), "KOI8-R.enc", "KOI8-U.enc", "CP1251.enc", "Greek.enc" (ISO 8859-7) and "CP1253.enc". Note that many glyphs in these encodings are not in the fonts corresponding to the standard families. (The Adobe ones for all but Courier, Helvetica and Times cover little more than Latin-1, whereas the URW ones also cover Latin-2, Latin-7, Latin-9 and Cyrillic but no Greek. The Adobe exceptions cover the Latin character sets, but not the Euro.)

If you specify the encoding, it is your responsibility to ensure that the PostScript font contains the glyphs used. One issue here is the Euro symbol which is in the WinAnsi and MacRoman encodings but may well not be in the PostScript fonts. (It is in the URW variants; it is not in the supplied Adobe Font Metric files.)

There is an exception. Character 45 ("-") is always set as minus (its value in Adobe ISOLatin1) even though it is hyphen in the other encodings. Hyphen is available as character 173 (octal 0255) in all the Latin encodings, Cyrillic and Greek. (This can be entered as "\uad" in a UTF-8 locale.) There are some discrepancies in accounts of glyphs 39 and 96: the supplied encodings (except CP1250 and CP1251) treat these as ‘quoteright’ and ‘quoteleft’ (rather than ‘quotesingle’/’acute’ and ‘grave’ respectively), as they are in the Adobe documentation.

TeX fonts

TeX has traditionally made use of fonts such as Computer Modern which are encoded rather differently, in a 7-bit encoding. This encoding can be specified by encoding = "TeXtext.enc", taking care that the ASCII characters < > \ _ { } are not available in those fonts.

There are supplied families "ComputerModern" and "ComputerModernItalic" which use this encoding, and which are only supported for postscript (and not pdf). They are intended to use with the Type 1 versions of the TeX CM fonts. It will normally be possible to include such output in TeX or LaTeX provided it is processed with dvips -Ppfb -j0 or the equivalent on your system. (-j0 turns off font subsetting.) When family = "ComputerModern" is used, the italic/bold-italic fonts used are slanted fonts (cmmi10 and cmmib10). To use text italic fonts instead, set family = "ComputerModernItalic".

These families use the TeX math italic and symbol fonts for a comprehensive but incomplete coverage of the glyphs covered by the Adobe symbol font in other families. This is achieved by special-casing the postscript code generated from the supplied ‘CM_symbol_10.afm’.

Color models

The default color model ("srgb") is sRGB.

The alternative "srgb+gray" uses sRGB for colors, but with pure gray colors (including black and white) expressed as greyscales (which results in smaller files and can be advantageous with some printer drivers). Conversely, its files can be rendered much slower on some viewers, and there can be a noticeable discontinuity in color gradients involving gray or white.

Other possibilities are "gray" (or "grey") which used only greyscales (and converts other colours to a luminance), and "cmyk". The simplest possible conversion from sRGB to CMYK is used (https://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK), and raster images are output in RGB.
Color models provided for backwards compatibility are "rgb" (which is RGB+gray) and "rgb-nogray" which use uncalibrated RGB (as used in R prior to 2.13.0). These result in slightly smaller files which may render faster, but do rely on the viewer being properly calibrated.

Printing

A postscript plot can be printed via `postscript` in two ways.

1. Setting `print.it = TRUE` causes the command given in argument `command` to be called with argument "file" when the device is closed. Note that the plot file is not deleted unless `command` arranges to delete it.
2. `file = ""` or `file = "|cmd"` can be used to print using a pipe. Failure to open the command will probably be reported to the terminal but not to R, in which case close the device by `dev.off` immediately.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

• The default device size is 7 inches square.
• Font sizes are in big points.
• The default font family is Helvetica.
• Line widths are as a multiple of 1/96 inch, with a minimum of 0.01 enforced.
• Circle of any radius are allowed.
• Colours are by default specified as sRGB.

At very small line widths, the line type may be forced to solid.

Raster images are currently limited to opaque colours.

Note

If you see problems with postscript output, do remember that the problem is much more likely to be in your viewer than in R. Try another viewer if possible. Symptoms for which the viewer has been at fault are apparent grids on image plots (turn off graphics anti-aliasing in your viewer if you can) and missing or incorrect glyphs in text (viewers silently doing font substitution).

Unfortunately the default viewers on most Linux and macOS systems have these problems, and no obvious way to turn off graphics anti-aliasing.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D’Urso <durso@hussle.harvard.edu>.

`postscriptFonts`, `Devices`, and `check.options` which is called from both `ps.options` and `postscript`.

`cairo_ps` for another device that can produce PostScript.

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in

Examples

```r
require(graphics)
## Not run:
# open the file "foo.ps" for graphics output
postscript("foo.ps")
# produce the desired graph(s)
dev.off() # turn off the postscript device
postscript("|lp -dlw")
# produce the desired graph(s)
dev.off() # plot will appear on printer

# for URW PostScript devices
postscript("foo.ps", family = "NimbusSan")

## for inclusion in Computer Modern TeX documents, perhaps
postscript("cm_test.eps", width = 4.0, height = 3.0,
  horizontal = FALSE, onefile = FALSE, paper = "special",
  family = "ComputerModern", encoding = "TeXtext.enc")
## The resultant postscript file can be used by dvips -Ppfb -j0.

## To test out encodings, you can use
TestChars <- function(encoding = "ISOLatin1", family = "URWHelvetica")
{
  postscript(encoding = encoding, family = family)
  par(pty = "s")
  plot(c(-1,16), c(-1,16), type = "n", xlab = "", ylab = "",
       xaxs = "i", yaxs = "i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty = 1)
  for(i in c(32:255)) {
    x <- i %% 16
    y <- i %/% 16
    points(x, y, pch = i)
  }
  dev.off()
}
## there will be many warnings. We use URW to get a complete enough
## set of font metrics.
TestChars()
TestChars("ISOLatin2")
TestChars("WinAnsi")

## End(Not run)
```
Description

These functions handle the translation of a \texttt{R} graphics font family name to a PostScript or PDF font description, used by the \texttt{postscript} or \texttt{pdf} graphics devices.

Usage

\begin{verbatim}
postscriptFonts(...)
pdfFonts(...)  
\end{verbatim}

Arguments

\begin{verbatim}
...  
\end{verbatim}

either character strings naming mappings to display, or named arguments specifying mappings to add or change.

Details

If these functions are called with no argument they list all the existing mappings, whereas if they are called with named arguments they add (or change) mappings.

A PostScript or PDF device is created with a default font family (see the documentation for \texttt{postscript}), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in \texttt{par} and for "fontfamily" in \texttt{gpar} in the \texttt{grid} package).

The font family sent to the device is a simple string name, which must be mapped to a set of PostScript fonts. Separate lists of mappings for \texttt{postscript} and \texttt{pdf} devices are maintained for the current \texttt{R} session and can be added to by the user.

The \texttt{postscriptFonts} and \texttt{pdfFonts} functions can be used to list existing mappings and to define new mappings. The \texttt{Type1Font} and \texttt{CIDFont} functions can be used to create new mappings, when the xxxFonts function is used to add them to the database. See the examples.

Default mappings are provided for three device-independent family names: "sans" for a sans-serif font (to "Helvetica"), "serif" for a serif font (to "Times") and "mono" for a monospaced font (to "Courier").

Mappings for a number of standard Adobe fonts (and URW equivalents) are also provided: "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" and "Times", "URW Gothic", "URW Bookman", "NimbusMon", "NimbusSan" (synonym "URW Helvetica"), "NimbusSanCond", "Century Sch", "URWPalladio" and "Nimbus Rom" (synonym "URW Times").

There are also mappings for "Computer Modern", "Computer Modern Italic" and "Arial MT" (Monotype Arial).

Finally, there are some default mappings for East Asian locales described in a separate section.

The specification of font metrics and encodings is described in the help for the \texttt{postscript} function.

The fonts are not embedded in the resulting PostScript or PDF file, so software including the PostScript or PDF plot file should either embed the font outlines (usually from ".pfb" or ".pfa"
files) or use DSC comments to instruct the print spooler or including application to do so (see also embedFonts).

A font family has both an R-level name, the argument name used when postscriptFonts was called, and an internal name, the family component. These two names are the same for all the pre-defined font families.

Once a font family is in use it cannot be changed. ‘In use’ means that it has been specified via a family or fonts argument to an invocation of the same graphics device already in the R session. (For these purposes xfig counts the same as postscript but only uses some of the predefined mappings.)

**Value**

A list of one or more font mappings.

**East Asian fonts**

There are some default mappings for East Asian locales:
"Japan1", "Japan1HeiMin", "Japan1GothicBBB", and "Japan1Ryumin" for Japanese; "Korea1" and "Korea1deb" for Korean; "GB1" (Simplified Chinese) for mainland China and Singapore; "CNS1" (Traditional Chinese) for Hong Kong and Taiwan.

These refer to the following fonts

- **Japan1 (PS)**: HeiseiKakuGo-W5
  - Linotype Japanese printer font

- **Japan1 (PDF)**: KozMinPro-Regular-Acro
  - from Adobe Reader 7.0 Japanese Font Pack

- **Japan1HeiMin (PS)**: HeiseiMin-W3
  - Linotype Japanese printer font

- **Japan1HeiMin (PDF)**: HeiseiMin-W3-Acro
  - from Adobe Reader 7.0 Japanese Font Pack

- **Japan1GothicBBB**: GothicBBB-Medium
  - Japanese-market PostScript printer font

- **Japan1Ryumin**: Ryumin-Light
  - Japanese-market PostScript printer font

- **Korea1 (PS)**: Baekmuk-Batang
  - TrueType font found on some Linux systems

- **Korea1 (PDF)**: HYSMyeongJoStd-Medium-Acro
  - from Adobe Reader 7.0 Korean Font Pack

- **Korea1deb (PS)**: Batang-Regular
  - another name for Baekmuk-Batang

- **Korea1deb (PDF)**: HYGothic-Medium-Acro
  - from Adobe Reader 4.0 Korean Font Pack

- **GB1 (PS)**: BousungEG-Light-GB
  - TrueType font found on some Linux systems

- **GB1 (PDF)**: STSong-Light-Acro
  - from Adobe Reader 7.0 Simplified Chinese Font Pack

- **CNS1 (PS)**: M0ESung-Regular
  - Ken Lunde's CJKV resources

- **CNS1 (PDF)**: MSungStd-Light-Acro
  - from Adobe Reader 7.0 Traditional Chinese Font Pack
BousungEG-Light-GB can be found at ftp://ftp.gnu.org/pub/non-gnu/chinese-fonts-truetype/. Ken Lunde’s CJKV resources are at ftp://ftp.oreilly.com/pub/examples/nutshell/cjkv/adobe/samples/. These will need to be installed or otherwise made available to the postscript/PDF interpreter such as ghostscript (and not all interpreters can handle TrueType fonts).

You may well find that your postscript/PDF interpreters has been set up to provide aliases for many of these fonts. For example, ghostscript on Windows can optionally be installed to map common East Asian fonts names to Windows TrueType fonts. (You may want to add the -Acro versions as well.)

Adding a mapping for a CID-keyed font is for gurus only.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D’Urso.

Examples

```r
postscriptFonts()
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
c("CM_regular_10.afm", "CM_boldx_10.afm",
"cmti10.afm", "cmbxti10.afm",
"CM_symbol_10.afm"),
encoding = "TeXtext.enc")
postscriptFonts(CMitalic = CMitalic)

## A CID font for Japanese using a different CMap and
## corresponding cmapEncoding.
"Jp_UCS-2" <- CIDFont("TestUCS2",
c("Adobe-Japan1-UniJIS-UCS2-H.afm",
"Adobe-Japan1-UniJIS-UCS2-H.afm",
"Adobe-Japan1-UniJIS-UCS2-H.afm",
"Adobe-Japan1-UniJIS-UCS2-H.afm"),
"UniJIS-UCS2-H", "UCS-2")
pdffonts("Jp_UCS-2" = "Jp_UCS-2")
names(pdffonts())
```

Description

Compute a sequence of about n+1 equally spaced ‘nice’ values which cover the range of the values in x, possibly of length one, when min.n = 0 and there is only one unique x.
ps.options

Auxiliary Function to Set/View Defaults for Arguments of postscript

Description

The auxiliary function ps.options can be used to set or view (if called without arguments) the default values for some of the arguments to postscript.

ps.options needs to be called before calling postscript, and the default values it sets can be overridden by supplying arguments to postscript.
ps.options

Usage

ps.options(..., reset = FALSE, override.check = FALSE)

setEPS(...)
setPS(...)

Arguments

... arguments onefile, family, title, fonts, encoding, bg, fg, width, height, horizontal, pointsize, paper, pagecentre, print.it, command, colormodel and fillOddEven can be supplied. onefile, horizontal and paper are ignored for setEPS and setPS.

reset logical: should the defaults be reset to their ‘factory-fresh’ values?

override.check logical argument passed to check.options. See the Examples.

Details

If both reset = TRUE and ... are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

For backwards compatibility argument append is accepted but ignored with a warning.

setEPS and setPS are wrappers to set defaults appropriate for figures for inclusion in documents (the default size is 7 inches square unless width or height is supplied) and for spooling to a PostScript printer respectively. For historical reasons the latter is the ultimate default.

Value

A named list of all the previous defaults. If ... or reset = TRUE is supplied the result has the visibility flag turned off.

See Also

postscript, pdf.options

Examples

ps.options(bg = "pink")
utils::str(ps.options())

### ---- error checking of arguments: ----
ps.options(width = 0:12, onefile = 0, bg = pi)
# override the check for 'width', but not 'bg':
ps.options(width = 0:12, bg = pi, override.check = c(TRUE, FALSE))
utils::str(ps.options())
ps.options(reset = TRUE) # back to factory-fresh
**quartz**

*macOS Quartz Device*

### Description

quartz starts a graphics device driver for the macOS System. It supports plotting both to the screen (the default) and to various graphics file formats.

### Usage

```r
quartz(title, width, height, pointsize, family, antialias, type,
       file = NULL, bg, canvas, dpi)
quartz.options(..., reset = FALSE)
quartz.save(file, type = "png", device = dev.cur(), dpi = 100, ...)
```

### Arguments

- **title**: title for the Quartz window (applies to on-screen output only), default "Quartz %d". A C-style format for an integer will be substituted by the device number (see the file argument to `postscript` for further details).
- **width**: the width of the plotting area in inches. Default 7.
- **height**: the height of the plotting area in inches. Default 7.
- **pointsize**: the default pointsize to be used. Default 12.
- **family**: this is the family name of the font that will be used by the device. Default "Arial". This will be the base name of a font as shown in Font Book.
- **antialias**: whether to use antialiasing. Default TRUE.
- **type**: the type of output to use. See `Details` for more information. Default "native".
- **file**: an optional target for the graphics device. The default, NULL, selects a default name where one is needed. See `Details` for more information.
- **bg**: the initial background colour to use for the device. Default "transparent". An opaque colour such as "white" will normally be required on off-screen types that support transparency such as "png" and "tiff".
- **canvas**: canvas colour to use for an on-screen device. Default "white", and will be forced to be an opaque colour.
- **dpi**: resolution of the output. The default (NA_real_) for an on-screen display defaults to the resolution of the main screen, and to 72 dpi otherwise. See `Details`.
- **...**: Any of the arguments to `quartz` except `file`.
- **reset**: logical: should the defaults be reset to their defaults?
- **device**: device number to copy from.
Details

The defaults for all but one of the arguments of `quartz` are set by `quartz.options`: the ‘Arguments’ section gives the ‘factory-fresh’ defaults.

The Quartz graphics device supports a variety of output types. On-screen output types are "" or "native" or "Cocoa". Off-screen output types produce output files and utilize the file argument. `type = "pdf"` gives PDF output. The following bitmap formats may be supported (depending on the OS version): "png", "jpeg", "jpg", "jpeg2000", "tiff", "tif", "gif", "psd" (Adobe Photoshop), "bmp" (Windows bitmap), "sgi" and "pict".

The file argument is used for off-screen drawing. The actual file is only created when the device is closed (e.g., using `dev.off()`). For the bitmap devices, the page number is substituted if a C integer format is included in the character string, e.g. Rplot%03d.png. (The result must be less than PATH_MAX characters long, and may be truncated if not. See `postscript` for further details.) If a file argument is not supplied, the default is Rplots.pdf or Rplot%03d.type. Tilde expansion (see `path.expand`) is done.

If a device-independent R graphics font family is specified (e.g., via `par(family =)` in the graphics package), the Quartz device makes use of the Quartz font database (see `quartzFonts`) to convert the R graphics font family to a Quartz-specific font family description. The default conversions are (MonoType TrueType versions of) Helvetica for sans, Times-Roman for serif and Courier for mono.

On-screen devices are launched with a semi-transparent canvas. Once a new plot is created, the canvas is first painted with the canvas colour and then the current background colour (which can be transparent or semi-transparent). Off-screen devices have no canvas colour, and so start with a transparent background where possible (e.g., `type = "png"` and `type = "tiff"`) – otherwise it appears that a solid white canvas is assumed in the Quartz code. PNG and TIFF files are saved with a dark grey matte which will show up in some viewers, including Preview.

`title` can be used for on-screen output. It must be a single character string with an optional integer printf-style format that will be substituted by the device number. It is also optionally used (without a format) to give a title to a PDF file.

Calling `quartz()` sets `.Device` to "quartz" for on-screen devices and to "quartz_off_screen" otherwise.

The font family chosen needs to cover the characters to be used: characters not in the font are rendered as empty oblongs. For non-Western-European languages something other than the default of "Arial" is likely to be needed—one choice for Chinese is "MingLiU".

`quartz.save` is a modified version of `dev.copy2pdf` to copy the plot from the current screen device to a quartz device, by default to a PNG file.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

• The default device size is 7 inches square.
• Font sizes are in big points.
• The default font family is Arial.
• Line widths are a multiple of 1/96 inch with no minimum set by R.
• Circle radii are real-valued with no minimum set by R.
• Colours are specified as sRGB.
### Note

For a long time the default font family was documented as "Helvetica" after it had been changed to "Arial" to work around a deficiency in macOS 10.4. It may be changed back in future.

A fairly common Mac problem is no text appearing on plots due to corrupted or duplicated fonts on your system. You may be able to confirm this by using another font family, e.g. family = "serif". Open the Font Book application (in Applications) and check the fonts that you are using.

### See Also

quartzFonts, Devices.

png for way to access the bitmap types of this device via R’s standard bitmap devices.

### Examples

```r
## Not run:
## put something like this is your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
  function(...) grDevices::quartz.options(width = 8, height = 6,
    pointsize = 10))
## End(Not run)

quartzFonts
```

---

### Description

These functions handle the translation of a device-independent R graphics font family name to a quartz font description.

### Usage

```r
quartzFont(family)
```

```r
quartzFonts(...)```

### Arguments

- **family**
  a character vector containing the four PostScript font names for plain, bold, italic, and bolditalic versions of a font family.

- **...**
  either character strings naming mappings to display, or new (named) mappings to define.

### Details

A quartz device is created with a default font (see the documentation for quartz), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for gpar in the grid package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to quartz fonts. A list of mappings is maintained and can be modified by the user.
The `quartzFonts` function can be used to list existing mappings and to define new mappings. The `quartzFont` function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font and "mono" for a monospaced font.

See Also

`quartz`

Examples

```r
quartzFonts()
quartzFonts("mono")
## Not run:
## for East Asian locales you can use something like
quartzFonts(sans = quartzFont(rep("AppleGothic", 4)),
  serif = quartzFont(rep("AppleMyungjp", 4)))
## since the default fonts may well not have the glyphs needed
## End(Not run)
```

recordGraphics

Record Graphics Operations

Description

Records arbitrary code on the graphics engine display list. Useful for encapsulating calculations with graphical output that depends on the calculations. Intended only for expert use.

Usage

```r
recordGraphics(expr, list, env)
```

Arguments

- `expr`: object of mode `expression` or call or an unevaluated expression.
- `list`: a list defining the environment in which `expr` is to be evaluated.
- `env`: An environment specifying where R looks for objects not found in `envir`.

Details

The code in `expr` is evaluated in an environment constructed from `list`, with `env` as the parent of that environment.

All three arguments are saved on the graphics engine display list so that on a device resize or copying between devices, the original evaluation environment can be recreated and the code can be re-evaluated to reproduce the graphical output.

Value

The value from evaluating `expr`. 
Warning

This function is not intended for general use. Incorrect or improper use of this function could lead to unintended and/or undesirable results.

An example of acceptable use is querying the current state of a graphics device or graphics system setting and then calling a graphics function.

An example of improper use would be calling the assign function to performing assignments in the global environment.

See Also

eval

Examples

```r
require(graphics)

plot(1:10)
# This rectangle remains 1 inch wide when the device is resized
recordGraphics(
  rect(4, 2,
      4 + diff(par("usr")[1:2])/par("pin")[1], 3)
),
list(),
getNamespace("graphics"))
```

---

### recordPlot

#### Record and Replay Plots

**Description**

Functions to save the current plot in an R variable, and to replay it.

**Usage**

```r
recordPlot(load=NULL, attach=NULL)
replayPlot(x, reloadPkgs=FALSE)
```

**Arguments**

- **load**: If not NULL, a character vector of package names, which are saved as part of the recorded plot.
- **attach**: If not NULL, a character vector of package names, which are saved as part of the recorded plot.
- **x**: A saved plot.
- **reloadPkgs**: A logical indicating whether to reload and/or reattach any packages that were saved as part of the recorded plot.
Details

These functions record and replay the displaylist of the current graphics device. The returned object is of class "recordedplot", and replayPlot acts as a print method for that class. The returned object is stored as a pairlist, but the usual methods for examining R objects such as deparse and str are liable to mislead.

Value

recordPlot returns an object of class "recordedplot".

replayPlot has no return value.

Warning

The format of recorded plots may change between R versions, so recorded plots should not be used as a permanent storage format for R plots.

As of R 3.3.0, it is possible (again) to replay a plot from another R session using, for example, saveRDS and readRDS. It is even possible to replay a plot from another R version, however, this will produce warnings, may produce errors, or something worse.

Note

Replay of a recorded plot may not produce the correct result (or may just fail) if the display list contains a call to recordGraphics which in turn contains an expression that calls code from a non-base package other than graphics or grid. The most well-known example of this is a plot drawn with the package ggplot2. One solution is to load the relevant package(s) before replaying the recorded plot. The load and attach arguments to recordPlot can be used to automate this - any packages named in load will be reloaded, via loadNamespace, and any packages named in attach will be reattached, via library, as long as reloadPkgs is TRUE in the call to replayPlot. This is only relevant when attempting to replay in one R session a plot that was recorded in a different R session.

See Also

The displaylist can be turned on and off using dev.control. Initially recording is on for screen devices, and off for print devices.

rgb

RGB Color Specification

Description

This function creates colors corresponding to the given intensities (between 0 and max) of the red, green and blue primaries. The colour specification refers to the standard sRGB colorspace (IEC standard 61966).

An alpha transparency value can also be specified (as an opacity, so 0 means fully transparent and max means opaque). If alpha is not specified, an opaque colour is generated.

The names argument may be used to provide names for the colors.

The values returned by these functions can be used with a col= specification in graphics functions or in par.
rgb

Usage

rgb(red, green, blue, alpha, names = NULL, maxColorValue = 1)

Arguments

red, blue, green, alpha
numeric vectors with values in \([0, M]\) where \(M\) is maxColorValue. When this
is 255, the red, blue, green, and alpha values are coerced to integers in \(0:255\)
and the result is computed most efficiently.

names character vector. The names for the resulting vector.

maxColorValue number giving the maximum of the color values range, see above.

Details

The colors may be specified by passing a matrix or data frame as argument red, and leaving blue
and green missing. In this case the first three columns of red are taken to be the red, green and
blue values.

Semi-transparent colors \((0 < \alpha < 1)\) are supported only on some devices: at the time of writing
on the pdf, windows, quartz and X11(type = “cairo”) devices and associated bitmap devices
(jpeg, png, bmp, tiff and bitmap). They are supported by several third-party devices such as those
in packages Cairo, cairoDevice and JavaGD. Only some of these devices support semi-transparent
backgrounds.

Most other graphics devices plot semi-transparent colors as fully transparent, usually with a warning
when first encountered.
NA values are not allowed for any of red, blue, green or alpha.

Value

A character vector with elements of 7 or 9 characters, "#" followed by the red, blue, green and
optionally alpha values in hexadecimal (after rescaling to \(0 \ldots 255\)). The optional alpha values
range from \(0\) (fully transparent) to \(255\) (opaque).

R does not use ‘premultiplied alpha’.

See Also

col2rgb for translating R colors to RGB vectors; rainbow, hsv, hcl, gray.

Examples

rgb(0, 1, 0)

rgb((0:15)/15, green = 0, blue = 0, names = paste("red", 0:15, sep = "."))

rgb(0, 0:12, 0, max = 255) \# integer input

ramp <- colorRamp(c("red", "white"))
rgb( ramp(seq(0, 1, length = 5)), max = 255)
Description
rgb2hsv transforms colors from RGB space (red/green/blue) into HSV space (hue/saturation/value).

Usage
rgb2hsv(r, g = NULL, b = NULL, maxColorValue = 255)

Arguments
r vector of ‘red’ values in \([0, M]\), \((M = \text{maxColorValue})\) or 3-row rgb matrix.
g vector of ‘green’ values, or NULL when \(r\) is a matrix.
b vector of ‘blue’ values, or NULL when \(r\) is a matrix.
maxColorValue number giving the maximum of the RGB color values range. The default 255 corresponds to the typical \(0:255\) RGB coding as in \text{col2rgb}().

Details
Value (brightness) gives the amount of light in the color.
Hue describes the dominant wavelength.
Saturation is the amount of Hue mixed into the color.
An HSV colorspace is relative to an RGB colorspace, which in \(R\) is sRGB, which has an implicit gamma correction.

Value
A matrix with a column for each color. The three rows of the matrix indicate hue, saturation and value and are named "h", "s", and "v" accordingly.

Author(s)
\(R\) interface by Wolfram Fischer \(<\text{wolfram@fischer-zim.ch}>\);
C code mainly by Nicholas Lewin-Koh \(<\text{nikko@hailmail.net}>\).

\text{hsv}, \text{col2rgb}, \text{rgb}.

Examples
## These (saturated, bright ones) only differ by hue
\(\text{rc} \leftarrow \text{col2rgb(c("red", "yellow","green","cyan", "blue", "magenta")})\)
\(\text{hc} \leftarrow \text{rgb2hsv(rc)}\)
6 * hc["h",] # the hues are equispaced

\(\text{rgb3} \leftarrow \text{floor}(256 \times \text{matrix}(\text{stats::runif(3*12)}, 3, 12))\)
(hsv3 <- rgb2hsv(rgb3))

## Consistency:
stopifnot(rgb3 == col2rgb(hsv(h = hsv3[1,], s = hsv3[2,], v = hsv3[3,])),
           all.equal(hsv3, rgb2hsv(rgb3/255, maxColorValue = 1)))

## A (simplified) pure R version -- originally by Wolfram Fischer --
## showing the exact algorithm:
rgb2hsvR <- function(rgb, gamma = 1, maxColorValue = 255)
{
  if(!is.numeric(rgb)) stop("rgb matrix must be numeric")
  d <- dim(rgb)
  if(d[1] != 3) stop("rgb matrix must have 3 rows")
  n <- d[2]
  if(n == 0) return(rbind(c(h = 1, s = 1, v = 1))[,0])
  rgb <- rgb/maxColorValue
  if(gamma != 1) rgb <- rgb ^ (1/gamma)

  ## get the max and min
  v <- apply( rgb, 2, max)
  s <- apply( rgb, 2, min)
  D <- v - s # range

  ## set hue to zero for undefined values (gray has no hue)
  h <- numeric(n)
  notgray <- ( s != v )

  ## blue hue
  idx <- (v == rgb[3,] & notgray )
  if (any (idx))
    h[idx] <- 2/3 + 1/6 * (rgb[1,idx] - rgb[2,idx]) / D[idx]

  ## green hue
  idx <- (v == rgb[2,] & notgray )
  if (any (idx))
    h[idx] <- 1/3 + 1/6 * (rgb[3,idx] - rgb[1,idx]) / D[idx]

  ## red hue
  idx <- (v == rgb[1,] & notgray )
  if (any (idx))

  ## correct for negative red
  idx <- (h < 0)
  h[idx] <- 1+h[idx]

  ## set the saturation
  s[! notgray] <- 0;
  s[notgray] <- 1 - s[notgray] / v[notgray]

  rbind( h = h, s = s, v = v )
}

## confirm the equivalence:
all.equal(rgb2hsv (rgb3),
           rgb2hsvR(rgb3), tolerance = 1e-14) # TRUE

savePlot
trans3d

Description

Projection of 3-dimensional to 2-dimensional points using a 4x4 viewing transformation matrix. Mainly for adding to perspective plots such as persp.

Usage

trans3d(x, y, z, pmat)
Arguments

\( x, \ y, \ z \) numeric vectors of equal length, specifying points in 3D space.

\( \text{pmat} \) a \( 4 \times 4 \) viewing transformation matrix, suitable for projecting the 3D coordinates \((x, y, z)\) into the 2D plane using homogeneous 4D coordinates \((x, y, z, t)\); such matrices are returned by \texttt{persp()}.

Value

a list with two components

\( x, y \) the projected 2d coordinates of the 3d input \((x, y, z)\).

\texttt{persp}

Examples

## See \texttt{help(persp)} \{after attaching the 'graphics' package\}
## --

---

\texttt{Type1Font} \hspace{1cm} \textit{Type 1 and CID Fonts}

Description

These functions are used to define the translation of a \texttt{R} graphics font family name to a Type 1 or CID font descriptions, used by both the \texttt{postscript} and \texttt{pdf} graphics devices.

Usage

\texttt{Type1Font(family, metrics, encoding = "default")}

\texttt{CIDFont(family, cmap, cmapEncoding, pdfresource = ")")}

Arguments

\texttt{family} a character string giving the name to be used internally for a Type 1 or CID-keyed font family. This needs to uniquely identify each family, so if you modify a family which is in use (see \texttt{postscriptFonts}) you need to change the family name.

metrics a character vector of four or five strings giving paths to the \texttt{afm} (Adobe Font Metric) files for the font.

cmap the name of a CMap file for a CID-keyed font.

encoding for \texttt{Type1Font}, the name of an encoding file. Defaults to "default", which maps on Unix-alikes to "ISOLatin1.enc" and on Windows to "WinAnsi.enc". Otherwise, a file name in the 'enc' directory of the \texttt{grDevices} package, which is used if the path does not contain a path separator. An extension ".enc" can be omitted.
cmapEncoding  The name of a character encoding to be used with the named CMap file: strings will be translated to this encoding when written to the file.

pdfresource  A chunk of PDF code; only required for using a CID-keyed font on pdf; users should not be expected to provide this.

Details

For Type1Fonts, if four `.afm` files are supplied the fifth is taken to be "Symbol.afm". Relative paths are taken relative to the directory `R_HOME/library/grDevices/afm`. The fifth (symbol) font must be in AdobeSym encoding. However, the glyphs in the first four fonts are referenced by name and any encoding given within the `.afm` files is not used.

The `.afm` files may be compressed with (or without) final extension `.gz`: the files which ship with R are installed as compressed files with this extension.

Glyphs in CID-keyed fonts are accessed by ID (number) and not by name. The CMap file maps encoded strings (usually in a MBCS) to IDs, so cmap and cmapEncoding specifications must match. There are no real bold or italic versions of CID fonts (bold/italic were very rarely used in traditional East Asian topography), and for the pdf device all four font faces will be identical. However, for the postscript device, bold and italic (and bold italic) are emulated.

CID-keyed fonts are intended only for use for the glyphs of East Asian languages, which are all monospaced and are all treated as filling the same bounding box. (Thus plotmath will work with such characters, but the spacing will be less carefully controlled than with Western glyphs.) The CID-keyed fonts do contain other characters, including a Latin alphabet: non-East-Asian glyphs are regarded as monospaced with half the width of East Asian glyphs. This is often the case, but sometimes Latin glyphs designed for proportional spacing are used (and may look odd). We strongly recommend that CID-keyed fonts are only used for East Asian glyphs.

Value

A list of class "Type1Font" or "CIDFont".

See Also

`postscript`, `pdf`, `postscriptFonts`, and `pdfFonts`.

Examples

```r
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
c("CM_regular_10.afm", "CM_boldx_10.afm",
"cmti10.afm", "cmbxti10.afm",
"CM_symbol_10.afm"),
encoding = "TeXtext.enc")

## Not run:
## This could be used by
postscript(family = CMitalic)
## or
postscriptFonts(CMitalic = CMitalic)  # once in a session
postscript(family = "CMitalic", encoding = "TeXtext.enc")

## End(Not run)
```
Description

X11 starts a graphics device driver for the X Window System (version 11). This can only be done on machines/accounts that have access to an X server.
x11 is recognized as a synonym for X11.
The R function is a wrapper for two devices, one based on Xlib (https://en.wikipedia.org/wiki/Xlib) and one using cairographics (http://www cairographics.org).

Usage

X11(display = "", width, height, pointsize, gamma, bg, canvas, fonts, family, xpos, ypos, title, type, antialias)

X11.options(..., reset = FALSE)

Arguments

display the display on which the graphics window will appear. The default is to use the value in the user's environment variable DISPLAY. This is ignored (with a warning) if an X11 device is already open on another display.

width, height the width and height of the plotting window, in inches. If NA, taken from the resources and if not specified there defaults to 7 inches. See also 'Resources'.

fontsize the default pointsize to be used. Defaults to 12.

gamma gamma correction fudge factor. Colours in R are sRGB; if your monitor does not conform to sRGB, you might be able to improve things by tweaking this parameter to apply additional gamma correction to the RGB channels. By default 1 (no additional gamma correction).

bg colour, the initial background colour. Default "transparent".

canvas colour. The colour of the canvas, which is visible only when the background colour is transparent. Should be an opaque colour (and any alpha value will be ignored). Default "white".

fonts for type = "Xlib" only: X11 font description strings into which weight, slant and size will be substituted. There are two, the first for fonts 1 to 4 and the second for font 5, the symbol font. See section 'Fonts'.

family The default family: a length-one character string. This is primarily intended for cairo-based devices, but for type = "Xlib", the X11Fonts() database is used to map family names to fonts (and this argument takes precedence over that one).

xpos, ypos integer: initial position of the top left corner of the window, in pixels. Negative values are from the opposite corner, e.g. xpos = -100 says the top right corner should be 100 pixels from the right edge of the screen. If NA (the default), successive devices are cascaded in 20 pixel steps from the top left. See also 'Resources'.
title character string, up to 100 bytes. With the default, "", a suitable title is created internally. A C-style format for an integer will be substituted by the device number (see the file argument to postscript for further details). How non-ASCII titles are handled is implementation-dependent.

type character string, one of "Xlib", "cairo", "nbcairo" or "dbcairo". Only the first will be available if the system was compiled without support for cairo-graphics. The default is "cairo" where available except on macOS, otherwise "Xlib".

antialias for cairo types, the type of anti-aliasing (if any) to be used. One of c("default", "none", "gray", "subpixel").

reset logical: should the defaults be reset to their defaults?

... Any of the arguments to X11, plus colortype and maxcubesize (see section 'Colour Rendering').

Details

The defaults for all of the arguments of X11 are set by X11.options: the ‘Arguments’ section gives the ‘factory-fresh’ defaults.

The initial size and position are only hints, and may not be acted on by the window manager. Also, some systems (especially laptops) are set up to appear to have a screen of a different size to the physical screen.

Option type selects between two separate devices: R can be built with support for neither, type = "Xlib" or both. Where both are available, types "cairo", "nbcairo" and "dbcairo" offer

- antialiasing of text and lines.
- translucent colours.
- scalable text, including to sizes like 4.5 pt.
- full support for UTF-8, so on systems with suitable fonts you can plot in many languages on a single figure (and this will work even in non-UTF-8 locales). The output should be locale-independent.

There are three variants of the cairo-based device. type = "nbcairo" has no buffering, type = "cairo" has some buffering, and supports dev.hold and dev.flush. type = "dbcairo" buffers output and updates the screen about every 100ms (by default). The refresh interval can be set (in units of seconds) by e.g. options(X11updates = 0.25): the value is consulted when a device is opened. Updates are only looked for every 50ms (at most), and during heavy graphics computations only every 500ms.

Which version will be fastest depends on the X11 connection and the type of plotting. You will probably want to use a buffered type unless backing store is in use on the X server (which for example it always is on macOS displays), as otherwise repainting when the window is exposed will be slow. On slow connections type = "dbcairo" will probably give the best performance.

Because of known problems with font selection on macOS without Pango (for example, the CRAN distribution), type = "cairo" is not the default there. These problems have included mixing up bold and italic (since worked around), selecting incorrect glyphs and ugly or missing symbol glyphs.

All devices which use an X11 server (including the type = "Xlib" versions of bitmap devices such as png) share internal structures, which means that they must use the same display and visual. If you want to change display, first close all such devices.
The cursor shown indicates the state of the device. If quiescent the cursor is an arrow: when the locator is in use it is a crosshair cursor, and when plotting computations are in progress (and this can be detected) it is a watch cursor. (The exact cursors displayed will depend on the window manager in use.)

X11 Fonts

This section applies only to type = "Xlib".

An initial/default font family for the device can be specified via the fonts argument, but if a device-independent R graphics font family is specified (e.g., via par(family =) in the graphics package), the X11 device makes use of the X11 font database (see X11Fonts) to convert the R graphics font family to an X11-specific font family description. If family is supplied as an argument, the X11 font database is used to convert that, but otherwise the argument fonts (with default given by X11.options) is used.

X11 chooses fonts by matching to a pattern, and it is quite possible that it will choose a font in the wrong encoding or which does not contain glyphs for your language (particularly common in iso10646-1 fonts).

The fonts argument is a two-element character vector, and the first element will be crucial in successfully using non-Western-European fonts. Settings that have proved useful include "*-mincho-%s-%s-%d-%s-*-*-*-*-*-*-*" for CJK languages and "-cronyx-helvetica-%s-%s-%d-%s-%s-%s-%s-%s" for Russian.

For UTF-8 locales, the XLC_LOCALE databases provide mappings between character encodings, and you may need to add an entry for your locale (e.g., Fedora Core 3 lacked one for ru_RU.utf8).

Cairo Fonts

The cairographics-based devices work directly with font family names such as "Helvetica" which can be selected initially by the family argument and subsequently by par or gpar. There are mappings for the three device-independent font families, "sans" for a sans-serif font (to "Helvetica"), "serif" for a serif font (to "Times") and "mono" for a monospaced font (to "Courier").

The font selection is handled by Pango (usually via fontconfig) or fontconfig (on macOS and perhaps elsewhere). The results depend on the fonts installed on the system running R – setting the environment variable FC_DEBUG to 1 normally allows some tracing of the selection process.

This works best when high-quality scalable fonts are installed, usually in Type 1 or TrueType formats: see the “R Installation and Administration Manual” for advice on how to obtain and install such fonts. At present the best rendering (including using kerning) will be achieved with TrueType fonts: see http://www.freedesktop.org/software/fontconfig/fontconfig-user.html for ways to set up your system to prefer them. The default family ("Helvetica") is likely not to use kerning: alternatives which should if you have them installed are "Arial", "DejaVu Sans" and "Liberation Sans" (and perhaps "FreeSans"). For those who prefer fonts with serifs, try "Times New Roman", "DejaVu Serif" and "Liberation Serif". To match LaTeX text, use something like "CM Roman".

Problems with incorrect rendering of symbols (e.g., of quote(pi) and expression(10^degree)) have been seen on Linux systems which have the Wine symbol font installed – fontconfig then prefers this and misinterprets its encoding. Adding the following lines to ‘~/.fonts.conf’ or ‘/etc/fonts/local.conf’ may circumvent this problem by preferring the URW Type 1 symbol font.

<fontconfig>
<match target="pattern">
A test for this is to run at the command line `fc-match Symbol`. If that shows `symbol.ttf` that may be the Wine symbol font – use `locate symbol.ttf` to see if it is found from a directory with ‘wine’ in the name.

**Resources**

The standard X11 resource `geometry` can be used to specify the window position and/or size, but will be overridden by values specified as arguments or non-NA defaults set in `X11.options`. The class looked for is `R_x11`. Note that the resource specifies the width and height in pixels and not in inches. See for example ‘`man X`’ (or [https://www.x.org/releases/current/](https://www.x.org/releases/current/)). An example line in ‘`~/.Xresources`’ might be

```
R_x11*geometry: 900x900-0+0
```

which specifies a 900 x 900 pixel window at the top right of the screen.

**Colour Rendering**

X11 supports several ‘visual’ types, and nowadays almost all systems support ‘truecolor’ which X11 will use by default. This uses a direct specification of any RGB colour up to the depth supported (usually 8 bits per colour). Other visuals make use of a palette to support fewer colours, only grays or even only black/white. The palette is shared between all X11 clients, so it can be necessary to limit the number of colours used by R.

The default for `type = "Xlib"` is to use the best possible colour model for the visual of the X11 server: these days this will almost always be ‘truecolor’. This can be overridden by the `colortype` argument of `X11.options`. **Note:** All X11 and `type = "Xlib"` bmp, jpeg, png and tiff devices share a `colortype` which is set when the first device to be opened. To change the `colortype` you need to close all open such devices, and then use `X11.options(colortype =)`.

The `colortype` types are tried in the order "true", "pseudo", "gray" and "mono" (black or white only). The values "pseudo" and "pseudo.cube" provide two colour strategies for a pseudocolor visual. The first strategy provides on-demand colour allocation which produces exact colours until the colour resources of the display are exhausted (when plotting will fail). The second allocates (if possible) a standard colour cube, and requested colours are approximated by the closest value in the cube.

With `colortype` equal to "pseudo.cube" or "gray" successively smaller palettes are tried until one is completely allocated. If allocation of the smallest attempt fails the device will revert to "mono". For "gray" the search starts at 256 grays for a display with depth greater than 8, otherwise with half the available colours. For "pseudo.cube" the maximum cube size is set by `X11.options(maxcolorsize =)` and defaults to 256. With that setting the largest cube tried is 4 levels each for RGB, using 64 colours in the palette.

The cairographics-based devices most likely only work (or work correctly) with ‘TrueColor’ visuals, although in principle this depends on the cairo installation: a warning is given if any other visual is encountered.

Anti-aliasing

Anti-aliasing is only supported for cairographics-based devices, and applies to both graphics and fonts. It is generally preferable for lines and text, but can lead to undesirable effects for fills, e.g. for `image` plots, and so is never used for fills.

antialias = "default" is in principle platform-dependent, but seems most often equivalent to antialias = "gray".

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

• The default device size is 7 inches square.
• Font sizes are in big points.
• The default font family is Helvetica.
• Line widths in 1/96 inch, minimum one pixel for type = "Xlib", 0.01 otherwise.
• For type = "Xlib" circle radii are in pixels with minimum one.
• Colours are interpreted by the X11 server, which is assumed to conform to sRGB.

Examples

```r
## Not run:
## put something like this in your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
         function(...) grDevices::X11.options(width = 8, height = 6, xpos = 0,
                        pointsize = 10))
## End(Not run)
```

---

**X11Fonts**

**X11 Fonts**

**Description**

These functions handle the translation of a device-independent R graphics font family name to an X11 font description.

**Usage**

`X11Font(font)`

`X11Fonts(...)`

**Arguments**

- `font` a character string containing an X11 font description.
- `...` either character strings naming mappings to display, or new (named) mappings to define.
Details

These functions apply only to an X11 device with type = "Xlib" – X11(type = "cairo") uses a different mechanism to select fonts.

Such a device is created with a default font (see the documentation for X11), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in par and for "fontfamily" in gpar in the grid package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to X11 fonts. A list of mappings is maintained and can be modified by the user.

The X11Fonts function can be used to list existing mappings and to define new mappings. The X11Font function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font and "mono" for a monospaced font. Further mappings are provided for "Helvetica" (the device default), "Times", "CyrHelvetica", "CyrTimes" (versions of these fonts with Cyrillic support, at least on Linux), "Arial" (on some platforms including macOS and Solaris) and "Mincho" (a CJK font).

utopia <- X11Font("*-*utopia-*-*-*-*-*-*-*-*-*-*-*-*")
X11Fonts(utopia = utopia)

xfig  XFig Graphics Device

Description

xfig starts the graphics device driver for producing XFig (version 3.2) graphics.

The auxiliary function ps.options can be used to set and view (if called without arguments) default values for the arguments to xfig and postscript.

Usage

xfig(file = if(onefile) "Rplots.fig" else "Rplot%03d.fig", 
onefile = FALSE, encoding = "none", 
paper = "default", horizontal = TRUE, 
width = 0, height = 0, family = "Helvetica", 
pointsize = 12, bg = "transparent", fg = "black", 
pagecentre = TRUE, defaultfont = FALSE, textspecial = FALSE)
Arguments

file a character string giving the name of the file. For use with onefile = FALSE
give a C integer format such as "Rplot%03d.fig" (the default in that case). (See
postscript for further details.)

onfile logical: if true allow multiple figures in one file. If false, assume only one page
per file and generate a file number containing the page number.

coding The encoding in which to write text strings. The default is not to re-encode.
This can be any encoding recognized by iconv: in a Western UTF-8 locale you
probably want to select an 8-bit encoding such as latin1, and in an East Asian
locale an EUC encoding. If re-encoding fails, the text strings will be written in
the current encoding with a warning.

coding the size of paper region. The choices are "A4", "Letter" and "Legal" (and
these can be lowercase). A further choice is "default", which is the default. If
this is selected, the papersize is taken from the option "papersize" if that is set
to a non-empty value, otherwise "A4".

coding the orientation of the printed image, a logical. Defaults to true, that is landscape
orientation.

coding the width and height of the graphics region in inches. The default is to use the
entire page less a 0.5 inch overall margin in each direction. (See postscript
for further details.)

coding the font family to be used. This must be one of "AvantGarde", "Bookman", "Courier", "Helvetica" (the default), "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times". Any other value is re-
placed by "Helvetica", with a warning.

coding the default point size to be used.

coding the initial background color to be used.

coding the initial foreground color to be used.

coding logical: should the device region be centred on the page?

coding logical: should the device use xfig’s default font?

coding logical: should the device set the textspecial flag for all text elements. This is
useful when generating pstex from xfig figures.

Details

Although xfig can produce multiple plots in one file, the XFig format does not say how to separate
or view them. So onefile = FALSE is the default.

The file argument is interpreted as a C integer format as used by sprintf, with integer argument
the page number. The default gives files ‘Rplot001.fig’, .., ‘Rplot999.fig’, ‘Rplot1000.fig’,
...

Line widths as controlled by par(lwd =) are in multiples of 5/6*1/72 inch. Multiples less than 1
are allowed. pch = "." with cex = 1 corresponds to a square of side 1/72 inch.

Windows users can make use of WinFIG (http://www.schmidt-web-berlin.de/WinFIG.htm,
shareware), or XFig under Cygwin.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R
Internals Manual”.

• The default device size is the paper size with a 0.25 inch border on all sides.
• Font sizes are in big points.
• The default font family is Helvetica.
• Line widths are integers, multiples of 5/432 inch.
• Circle radii are multiples of 1/1200 inch.
• Colours are interpreted by the viewing/printing application.

Note

Only some line textures \((0 \leq lty < 4)\) are used. Eventually this may be partially remedied, but the XFig file format does not allow as general line textures as the R model. Unimplemented line textures are displayed as dash-double-dotted.

There is a limit of 512 colours (plus white and black) per file.

xy.coords | Extracting Plotting Structures

Description

xy.coords is used by many functions to obtain x and y coordinates for plotting. The use of this common mechanism across all relevant R functions produces a measure of consistency.

Usage

```r
xy.coords(x, y = NULL, xlab = NULL, ylab = NULL, log = NULL,
           recycle = FALSE, setLab = TRUE)
```

Arguments

- `x, y` the x and y coordinates of a set of points. Alternatively, a single argument `x` can be provided.
- `xlab, ylab` names for the x and y variables to be extracted.
- `log` character, "x", "y" or both, as for `plot`. Sets negative values to `NA` and gives a warning.
- `recycle` logical; if TRUE, recycle (rep) the shorter of x or y if their lengths differ.
- `setLab` logical indicating if the resulting `xlab` and `ylab` should be constructed from the "kind" of \((x,y)\); otherwise, the arguments `xlab` and `ylab` are used.
Details

An attempt is made to interpret the arguments x and y in a way suitable for bivariate plotting (or other bivariate procedures).

If y is NULL and x is a

**formula:** of the form yvar ~ xvar. xvar and yvar are used as x and y variables.

**list:** containing components x and y, these are used to define plotting coordinates.

**time series:** the x values are taken to be \texttt{time(x)} and the y values to be the time series.

**matrix or \texttt{data.frame} with two or more columns:** the first is assumed to contain the x values and the second the y values. \textit{Note} that is also true if x has columns named "x" and "y"; these names will be irrelevant here.

In any other case, the x argument is coerced to a vector and returned as y component where the resulting x is just the index vector 1:n. In this case, the resulting xlab component is set to "Index" (if setLab is true as by default).

If x (after transformation as above) inherits from class "POSIXt" it is coerced to class "POSIXct".

Value

A list with the components

- **x** numeric (i.e., "double") vector of abscissa values.
- **y** numeric vector of the same length as x.
- **xlab** character(1) or NULL, the 'label' of x.
- **ylab** character(1) or NULL, the 'label' of y.

See Also

\texttt{plot.default}, \texttt{lines}, \texttt{points} and \texttt{lowess} are examples of functions which use this mechanism.

Examples

```r
def <- stats::fft(1:9)
xy.coords(def)
xy.coords(def, xlab = "fft") # labels "Re(fft)", "Im(fft)"

with(cars, xy.coords(dist ~ speed, NULL)$xlab ) # = "speed"

xy.coords(1:3, 1:2, recycle = TRUE) # otherwise error "lengths differ"
xy.coords(-2:10, log = "y")
##> xlab: "Index" \ warning: 3 y values <= 0 omitted ..
```
xyTable

Multiplicities of (x,y) Points, e.g., for a Sunflower Plot

Description

Given (x,y) points, determine their multiplicity – checking for equality only up to some (crude kind of) noise. Note that this is special kind of 2D binning.

Usage

xyTable(x, y = NULL, digits)

Arguments

x, y numeric vectors of the same length; alternatively other (x, y) argument combinations as allowed by xy.coords(x, y).

digits integer specifying the significant digits to be used for determining equality of coordinates. These are compared after rounding them via signif(*, digits).

Value

A list with three components of same length,

x x coordinates, rounded and sorted.
y y coordinates, rounded (and sorted within x).

number multiplicities (positive integers); i.e., number[i] is the multiplicity of (x[i], y[i]).

See Also

sunflowerplot which typically uses xyTable(); signif.

Examples

xyTable(iris[, 3:4], digits = 6)

## Discretized uncorrelated Gaussian:

require(stats)
xy <- data.frame(x = round(sort(rnorm(100))), y = rnorm(100))
xyTable(xy, digits = 1)
xyz.coords

Extracting Plotting Structures

Description

Utility for obtaining consistent x, y and z coordinates and labels for three dimensional (3D) plots.

Usage

```r
xyz.coords(x, y = NULL, z = NULL,
            xlab = NULL, ylab = NULL, zlab = NULL,
            log = NULL, recycle = FALSE, setLab = TRUE)
```

Arguments

- `x, y, z`: the x, y and z coordinates of a set of points. Both y and z can be left at `NULL`. In this case, an attempt is made to interpret x in a way suitable for plotting.
- `xlab, ylab, zlab`: names for the x, y and z variables to be extracted.
- `log`: character, "x", "y", "z" or combinations. Sets negative values to `NA` and gives a warning.
- `recycle`: logical; if TRUE, recycle (rep) the shorter ones of x, y or z if their lengths differ.
- `setLab`: logical indicating if the resulting xlab and ylab should be constructed from the “kind” of (x,y); otherwise, the arguments xlab and ylab are used.

Value

A list with the components

- `x`: numeric (i.e., `double`) vector of abscissa values.
- `y`: numeric vector of the same length as `x`.
- `z`: numeric vector of the same length as `x`.
- `xlab`: character(1) or `NULL`, the axis label of `x`.
- `ylab`: character(1) or `NULL`, the axis label of `y`.
- `zlab`: character(1) or `NULL`, the axis label of `z`.

The graphics package

---

**graphics-package**  *The R Graphics Package*

---

**Description**

R functions for base graphics

**Details**

This package contains functions for ‘base’ graphics. Base graphics are traditional S-like graphics, as opposed to the more recent grid graphics.

For a complete list of functions with individual help pages, use `library(help = "graphics")`.

**Author(s)**

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

**References**

---

**abline**  *Add Straight Lines to a Plot*

---

**Description**

This function adds one or more straight lines through the current plot.

**Usage**

```
abline(a = NULL, b = NULL, h = NULL, v = NULL, reg = NULL, 
       coef = NULL, untf = FALSE, ...)
```
Arguments

- **a, b**: the intercept and slope, single values.
- **untf**: logical asking whether to *untransform*. See ‘Details’.
- **h**: the y-value(s) for horizontal line(s).
- **v**: the x-value(s) for vertical line(s).
- **coef**: a vector of length two giving the intercept and slope.
- **reg**: an object with a `coef` method. See ‘Details’.
- ... *graphical parameters* such as `col`, `lty` and `lwd` (possibly as vectors: see ‘Details’) and `xpd` and the line characteristics `lend`, `ljoin` and `lmitre`.

Details

Typical usages are

```r
abline(a, b, untf = FALSE, ...)
abline(h =, untf = FALSE, ...)
abline(v =, untf = FALSE, ...)
abline(coef =, untf = FALSE, ...)
abline(reg =, untf = FALSE, ...)
```

The first form specifies the line in intercept/slope form (alternatively `a` can be specified on its own and is taken to contain the slope and intercept in vector form).

The `h=` and `v=` forms draw horizontal and vertical lines at the specified coordinates.

The `coef` form specifies the line by a vector containing the slope and intercept.

`reg` is a regression object with a `coef` method. If this returns a vector of length 1 then the value is taken to be the slope of a line through the origin, otherwise, the first 2 values are taken to be the intercept and slope.

If `untf` is true, and one or both axes are log-transformed, then a curve is drawn corresponding to a line in original coordinates, otherwise a line is drawn in the transformed coordinate system. The `h` and `v` parameters always refer to original coordinates.

The *graphical parameters* `col`, `lty` and `lwd` can be specified; see `par` for details. For the `h=` and `v=` usages they can be vectors of length greater than one, recycled as necessary.

Specifying an `xpd` argument for clipping overrides the global `par` (“xpd”) setting used otherwise.

References

See Also

- `lines` and `segments` for connected and arbitrary lines given by their endpoints. `par`. 
Examples

```r
## Setup up coordinate system (with x == y aspect ratio):
plot(c(-2,3), c(-1,5), type = "n", xlab = "x", ylab = "y", asp = 1)
## the x- and y-axis, and an integer grid
abline(h = 0, v = 0, col = "gray60")
text(1,0, "abline( h = 0 )", col = "gray60", adj = c(0, -.1))
abline(h = -1:5, v = -2:3, col = "lightgray", lty = 3)
abline(a = 1, b = 2, col = 2)
text(1,3, "abline( 1, 2 )", col = 2, adj = c(-.1, -.1))

## Simple Regression Lines:
require(stats)
sale5 <- c(6, 4, 9, 7, 6, 12, 8, 10, 9, 13)
plot(sale5)
abline(lsfit(1:10, sale5))
abline(lsfit(1:10, sale5, intercept = FALSE), col = 4) # less fitting

z <- lm(dist ~ speed, data = cars)
plot(cars)
abline(z) # equivalent to abline(reg = z) or
abline(coef = coef(z))

## trivial intercept model
abline(mC <- lm(dist ~ 1, data = cars)) ## the same as
abline(a = coef(mC), b = 0, col = "blue")
```

---

**arrows**

### Add Arrows to a Plot

#### Description

Draw arrows between pairs of points.

#### Usage

```r
arrows(x0, y0, x1 = x0, y1 = y0, length = 0.25, angle = 30,
       code = 2, col = par("fg"), lty = par("lty"),
       lwd = par("lwd"), ...)  
```

#### Arguments

- `x0`, `y0` coordinates of points from which to draw.
- `x1`, `y1` coordinates of points to which to draw. At least one must be supplied.
- `length` length of the edges of the arrow head (in inches).
- `angle` angle from the shaft of the arrow to the edge of the arrow head.
- `code` integer code, determining kind of arrows to be drawn.
- `col`, `lty`, `lwd` graphical parameters, possible vectors. NA values in `col` cause the arrow to be omitted.
- `...` graphical parameters such as `xpd` and the line characteristics `lend`, `ljoin` and `lmitre`: see `par`.  

assocplot

Details
For each i, an arrow is drawn between the point \((x0[i], y0[i])\) and the point \((x1[i], y1[i])\). The coordinate vectors will be recycled to the length of the longest.

If code = 1 an arrowhead is drawn at \((x0[i], y0[i])\) and if code = 2 an arrowhead is drawn at \((x1[i], y1[i])\). If code = 3 a head is drawn at both ends of the arrow. Unless length = 0, when no head is drawn.

The graphical parameters col, lty and lwd can be vectors of length greater than one and will be recycled if necessary.

The direction of a zero-length arrow is indeterminate, and hence so is the direction of the arrowheads. To allow for rounding error, arrowheads are omitted (with a warning) on any arrow of length less than 1/1000 inch.

Note
The first four arguments in the comparable S function are named x1, y1, x2, y2.

References

See Also
segments to draw segments.

Examples
```r
x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x, y); x <- x[i]; y <- y[i]
plot(x,y, main = "arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1) # one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col = 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col = "pink")
```

assocplot Association Plots

Description
Produce a Cohen-Friendly association plot indicating deviations from independence of rows and columns in a 2-dimensional contingency table.

Usage
```r
assocplot(x, col = c("black", "red"), space = 0.3, main = NULL, xlab = NULL, ylab = NULL)
```
Arguments

- **x**: a two-dimensional contingency table in matrix form.
- **col**: a character vector of length two giving the colors used for drawing positive and negative Pearson residuals, respectively.
- **space**: the amount of space (as a fraction of the average rectangle width and height) left between each rectangle.
- **main**: overall title for the plot.
- **xlab**: a label for the x axis. Defaults to the name (if any) of the row dimension in x.
- **ylab**: a label for the y axis. Defaults to the name (if any) of the column dimension in x.

Details

For a two-way contingency table, the signed contribution to Pearson’s \( \chi^2 \) for cell \( i,j \) is \( d_{ij} = (f_{ij} - e_{ij})/\sqrt{e_{ij}} \), where \( f_{ij} \) and \( e_{ij} \) are the observed and expected counts corresponding to the cell. In the Cohen-Friendly association plot, each cell is represented by a rectangle that has (signed) height proportional to \( d_{ij} \) and width proportional to \( \sqrt{e_{ij}} \), so that the area of the box is proportional to the difference in observed and expected frequencies. The rectangles in each row are positioned relative to a baseline indicating independence (\( d_{ij} = 0 \)). If the observed frequency of a cell is greater than the expected one, the box rises above the baseline and is shaded in the color specified by the first element of col, which defaults to black; otherwise, the box falls below the baseline and is shaded in the color specified by the second element of col, which defaults to red.

A more flexible and extensible implementation of association plots written in the grid graphics system is provided in the function **assoc** in the contributed package vcd (Meyer, Zeileis and Hornik, 2005).

Examples

```r
## Aggregate over sex:
x <- margin.table(HairEyeColor, c(1, 2))
x
assocplot(x, main = "Relation between hair and eye color")
```
Axis

Generic Function to Add an Axis to a Plot

Description
Generic function to add a suitable axis to the current plot.

Usage
Axis(x = NULL, at = NULL, ..., side, labels = NULL)

Arguments
x an object which indicates the range over which an axis should be drawn
at the points at which tick-marks are to be drawn.
side an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
labels this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. If this is specified as a character or expression vector, at should be supplied and they should be the same length.
... Arguments to be passed to methods and perhaps then to axis.

Details
This is a generic function. It works in a slightly non-standard way: if x is supplied and non-NULL it dispatches on x, otherwise if at is supplied and non-NULL it dispatches on at, and the default action is to call axis, omitting argument x.

The idea is that for plots for which either or both of the axes are numerical but with a special interpretation, the standard plotting functions (including boxplot, contour, coplot, filled.contour, pairs, plot.default, rug and stripchart) will set up user coordinates and Axis will be called to label them appropriately.

There are "Date" and "POSIXt" methods which can pass an argument format on to the appropriate axis method (see axis.POSIXct).

Value
The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see 'Details').

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

See Also
axis.
**axis**

**Add an Axis to a Plot**

**Description**

Adds an axis to the current plot, allowing the specification of the side, position, labels, and other options.

**Usage**

```r
axis(side, at = NULL, labels = TRUE, tick = TRUE, line = NA,
pos = NA, outer = FALSE, font = NA, lty = "solid",
lwd = 1, lwd.ticks = lwd, col = NULL, col.ticks = NULL,
hadj = NA, padj = NA, ...)
```

**Arguments**

- `side`: an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
- `at`: the points at which tick-marks are to be drawn. Non-finite (infinite, NaN or NA) values are omitted. By default (when NULL) tickmark locations are computed, see ‘Details’ below.
- `labels`: this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. (Other objects are coerced by `as.graphicsAnnot`.) If this is not logical, at should also be supplied and of the same length. If `labels` is of length zero after coercion, it has the same effect as supplying `TRUE`.
- `tick`: a logical value specifying whether tickmarks and an axis line should be drawn.
- `line`: the number of lines into the margin at which the axis line will be drawn, if not NA.
- `pos`: the coordinate at which the axis line is to be drawn: if not NA this overrides the value of `line`.
- `outer`: a logical value indicating whether the axis should be drawn in the outer plot margin, rather than the standard plot margin.
- `font`: font for text. Defaults to `par("font")`.
- `lty`: line type for both the axis line and the tick marks.
- `lwd`, `lwd.ticks`: line widths for the axis line and the tick marks. Zero or negative values will suppress the line or ticks.
- `col`, `col.ticks`: colors for the axis line and the tick marks respectively. `col = NULL` means to use `par("fg")`, possibly specified inline, and `col.ticks = NULL` means to use whatever color `col` resolved to.
- `hadj`: adjustment (see `par("adj")`) for all labels parallel (‘horizontal’) to the reading direction. If this is not a finite value, the default is used (centring for strings parallel to the axis, justification of the end nearest the axis otherwise).
- `padj`: adjustment for each tick label perpendicular to the reading direction. For labels parallel to the axes, `padj = 0` means right or top alignment, and `padj = 1` means left or bottom alignment. This can be a vector given a value for each string, and will be recycled as necessary.
If padj is not a finite value (the default), the value of par("las") determines
the adjustment. For strings plotted perpendicular to the axis the default is to
centre the string.

other graphical parameters may also be passed as arguments to this function,
particularly, cex.axis, col.axis and font.axis for axis annotation, mgp and
xaxp or yaxp for positioning, tck or tcl for tick mark length and direction,
las for vertical/horizontal label orientation, or fg instead of col, and xpd for
clipping. See par on these.
Parameters xaxt (sides 1 and 3) and yaxt (sides 2 and 4) control if the axis is
plotted at all.
Note that lab will partial match to argument labels unless the latter is also
supplied. (Since the default axes have already been set up by plot.window, lab
will not be acted on by axis.)

Details

The axis line is drawn from the lowest to the highest value of at, but will be clipped at the plot
region. By default, only ticks which are drawn from points within the plot region (up to a tolerance
for rounding error) are plotted, but the ticks and their labels may well extend outside the plot region.
Use xpd = TRUE or xpd = NA to allow axes to extend further.

When at = NULL, pretty tick mark locations are computed internally (the same way axTicks(side)
would) from par("xaxp") or "yaxp" and par("xlog") (or "ylog"). Note that these locations may
change if an on-screen plot is resized (for example, if the plot argument asp (see plot.window) is
set.)
If labels is not specified, the numeric values supplied or calculated for at are converted to character
strings as if they were a numeric vector printed by print.default(digits = 7).
The code tries hard not to draw overlapping tick labels, and so will omit labels where they would
abut or overlap previously drawn labels. This can result in, for example, every other tick being
labelled. (The ticks are drawn left to right or bottom to top, and space at least the size of an ‘m’ is
left between labels.)
If either line or pos is set, they (rather than par("mgp")[3]) determine the position of the axis
line and tick marks, and the tick labels are placed par("mgp")[2] further lines into (or towards for
pos) the margin.
Several of the graphics parameters affect the way axes are drawn. The vertical (for sides 1 and 3)
positions of the axis and the tick labels are controlled by mgp[2:3] and mex, the size and direction of
the ticks is controlled by tck and tcl and the appearance of the tick labels by cex.axis, col.axis
and font.axis with orientation controlled by las (but not srt, unlike S which uses srt if at is
supplied and 1as if it is not). Note that adj is not supported and labels are always centered. See
par for details.

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first
drawn (see ‘Details’).
This function is usually invoked for its side effect, which is to add an axis to an already existing
plot.

References

Brooks/Cole.
**axis.POSIXct**

See Also

*Axis* for a generic interface.

*axTicks* returns the axis tick locations corresponding to `at = NULL`; *pretty* is more flexible for computing pretty tick coordinates and does *not* depend on (nor adapt to) the coordinate system in use.

Several graphics parameters affecting the appearance are documented in *par*.

**Examples**

```r
require(stats) # for rnorm
plot(1:4, rnorm(4), axes = FALSE)
axis(1, 1:4, LETTERS[1:4])
aaxis(2)
box() #- to make it look "as usual"

plot(1:7, rnorm(7), main = "axis() examples",
     type = "s", xaxt = "n", frame = FALSE, col = "red")
aaxis(1, 1:7, LETTERS[1:7], col.axis = "blue")
# unusual options:
aaxis(4, col = "violet", col.axis = "dark violet", lwd = 2)
aaxis(3, col = "gold", lty = 2, lwd = 0.5)

# one way to have a custom x axis
plot(1:10, xaxt = "n")
aaxis(1, xaxp = c(2, 9, 7))
```

---

**axis.POSIXct**  
**Date and Date-time Plotting Functions**

**Description**

Functions to plot objects of classes "POSIXlt", "POSIXct" and "Date" representing calendar dates and times.

**Usage**

```r
axis.POSIXct(side, x, at, format, labels = TRUE, ...)
aaxis.Date(side, x, at, format, labels = TRUE, ...)
```

**Arguments**

- `x, at`  
  A date-time or date object.

- `side`  
  See *axis*.

- `format`  
  See *strptime*.

- `labels`  
  Either a logical value specifying whether annotations are to be made at the tickmarks, or a vector of character strings to be placed at the tickpoints.

- `...`  
  Further arguments to be passed from or to other methods, typically graphical parameters.
Details

axis.POSIXct and axis.Date work quite hard to choose suitable time units (years, months, days, hours, minutes or seconds) and a sensible output format, but this can be overridden by supplying a format specification.

If at is supplied it specifies the locations of the ticks and labels whereas if x is specified a suitable grid of labels is chosen. Printing of tick labels can be suppressed by using labels = FALSE.

The date-times for a "POSIXct" input are interpreted in the time zone give by the "tzone" attribute if there is one, otherwise the current time zone.

The way the date-times are rendered (especially month names) is controlled by the locale setting of category "LC_TIME" (see Sys.setlocale).

Value

The locations on the axis scale at which tick marks were drawn.

See Also

DateTimeClasses, Dates for details of the classes.

Axis.

Examples

```r
with(beaver1, {
  time <- strptime(paste(1990, day, time %/% 100, time %% 100),
               "%Y %j %H %M")
  plot(time, temp, type = "l") # axis at 4-hour intervals.
  # now label every hour on the time axis
  r <- as.POSIXct(round(range(time), "hours"))
  axis.POSIXct(1, at = seq(r[1], r[2], by = "hour"), format = "%H")
})

plot(.leap.seconds, seq_along(.leap.seconds), type = "n", xaxt = "n",
     xlab = "leap seconds", ylab = "", bty = "n")
rug(.leap.seconds)
## or as dates
lps <- as.Date(.leap.seconds)
plot(lps, seq_along(.leap.seconds),
     type = "n", xaxt = "n", xlab = "leap seconds",
     ylab = "", bty = "n")
rug(lps)
## 100 random dates in a 10-week period
random.dates <- as.Date("2001/1/1") + 70*sort(stats::runif(100))
plot(random.dates, 1:100)
# or for a better axis labelling
plot(random.dates, 1:100, xaxt = "n")
axis.Date(1, at = seq(as.Date("2001/1/1"), max(random.dates)+6, "weeks"))
axis.Date(1, at = seq(as.Date("2001/1/1"), max(random.dates)+6, "days"),
           labels = FALSE, tcl = -0.2)
```
### axTicks

**Compute Axis Tickmark Locations**

**Description**

Compute pretty tickmark locations, the same way as \texttt{R} does internally. This is only non-trivial when \texttt{log} coordinates are active. By default, gives the at values which \texttt{axis(side)} would use.

**Usage**

\begin{verbatim}
axTicks(side, axp = NULL, usr = NULL, log = NULL, nintLog = NULL)
\end{verbatim}

**Arguments**

- \texttt{side} integer in 1:4, as for \texttt{axis}.
- \texttt{axp} numeric vector of length three, defaulting to \texttt{par("xaxp")} or \texttt{par("yaxp")} depending on the \texttt{side} argument (\texttt{par("xaxp")} if \texttt{side} is 1 or 3, \texttt{par("yaxp")} if \texttt{side} is 2 or 4).
- \texttt{usr} numeric vector of length two giving user coordinate limits, defaulting to the relevant portion of \texttt{par("usr")} \texttt{par("usr")[1:2]} or \texttt{par("usr")[3:4]} for \texttt{side} in (1,3) or (2,4) respectively.
- \texttt{log} logical indicating if log coordinates are active; defaults to \texttt{par("xlog")} or \texttt{par("ylog")} depending on \texttt{side}.
- \texttt{nintLog} (only used when \texttt{log} is true): approximate (lower bound for the) number of tick intervals; defaults to \texttt{par("lab")[j]} where \texttt{j} is 1 or 2 depending on \texttt{side}. Set this to \texttt{Inf} if you want the same behavior as in earlier \texttt{R} versions (than 2.14.x).

**Details**

The \texttt{axp}, \texttt{usr}, and \texttt{log} arguments must be consistent as their default values (the \texttt{par(\ldots)} results) are. If you specify all three (as non-\texttt{NULL}), the graphics environment is not used at all. Note that the meaning of \texttt{axp} differs significantly when \texttt{log} is \texttt{TRUE}; see the documentation on \texttt{par(xaxp = \ldots)}. \texttt{axTicks()} can be used an \texttt{R} interface to the \texttt{C} function \texttt{CreateAtVector()} in ‘\ldots/src/main/plot.c’ which is called by \texttt{axis(side, \*\*)} when no argument at is specified. The delicate case, \texttt{log = TRUE}, now makes use of \texttt{axisTicks} (in package \texttt{grDevices}) unless \texttt{nintLog = Inf} which exists for back compatibility.

**Value**

numeric vector of coordinate values at which axis tickmarks can be drawn. By default, when only the first argument is specified, these values should be identical to those that \texttt{axis(side)} would use or has used. Note that the values are decreasing when \texttt{usr} is (‘reverse axis” case).

**See Also**

\texttt{axis, par, pretty} uses the same algorithm (but independently of the graphics environment) and has more options. However it is not available for \texttt{log = TRUE}.

\texttt{axisTicks()} (package \texttt{grDevices}).
Examples

```r
plot(1:7, 10*21:27)
axTicks(1)
axTicks(2)
stopifnot(identical(axTicks(1), axTicks(3)),
          identical(axTicks(2), axTicks(4)))
```

```r
## Show how axTicks() and axis() correspond :
op <- par(mfrow = c(3, 1))
for(x in 9999 * c(1, 2, 8)) {
  plot(x, 9, log = "x")
  cat(formatC(par("xaxp"), width = 5), ";", T <- axTicks(1), \n"
    rug(T, col = adjustcolor("red", 0.5), lwd = 4)
}
par(op)
```

```r
x <- 9.9*10^(-3:10)
plot(x, 1:14, log = "x")
axTicks(1) # now length 5, in R <= 2.13.x gave the following
axTicks(1, nintLog = Inf) # rather too many
```

```r
## An example using axTicks() without reference to an existing plot
## (copying R’s internal procedures for setting axis ranges etc.),
## You do need to supply _all_ of axp, usr, log, nintLog
## standard logarithmic y axis labels
ylims <- c(0.2, 88)
get_axp <- function(x) 10^c(ceiling(x[1]), floor(x[2]))
axp <- par("yaxp")
usr.i <- log10(ylims)
(aT.i <- axTicks(side = 2, usr = usr.i,
               axp = c(get_axp(usr.i), n = 3), log = TRUE, nintLog = 5))
```

```r
## mimic (default) par("yaxs") == "r"
usr.r <- extendrange(r = log10(ylims), f = 0.04)
(aT.r <- axTicks(side = 2, usr = usr.r,
               axp = c(get_axp(usr.r), 3), log = TRUE, nintLog = 5))
```

```r
## Prove that we got it right :
plot(0:1, ylims, log = "y", yaxs = "i")
stopifnot(all.equal(aT.i, axTicks(side = 2)))
```

```r
plot(0:1, ylims, log = "y", yaxs = "r")
stopifnot(all.equal(aT.r, axTicks(side = 2)))
```

---

**barplot**

**Bar Plots**

**Description**

Creates a bar plot with vertical or horizontal bars.

**Usage**

`barplot(height, ...)`
## Default S3 method:
barplot(height, width = 1, space = NULL,
    names.arg = NULL, legend.text = NULL, beside = FALSE,
    horiz = FALSE, density = NULL, angle = 45,
    col = NULL, border = par("fg"),
    main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
    xlim = NULL, ylim = NULL, xpd = TRUE, log = "",
    axes = TRUE, axisnames = TRUE,
    cex.axis = par("cex.axis"), cex.names = par("cex.axis"),
    inside = TRUE, plot = TRUE, axis.lty = 0, offset = 0,
    add = FALSE, args.legend = NULL, ...)

Arguments

**height**
either a vector or matrix of values describing the bars which make up the plot.
If height is a vector, the plot consists of a sequence of rectangular bars with
eheights given by the values in the vector. If height is a matrix and beside is FALSE then each bar of the plot corresponds to a column of height, with the
tvalues in the column giving the heights of stacked sub-bars making up the bar.
If height is a matrix and beside is TRUE, then the values in each column are
juxtaposed rather than stacked.

**width**
optional vector of bar widths. Re-cycled to length the number of bars drawn.
Specifying a single value will have no visible effect unless xlim is specified.

**space**
the amount of space (as a fraction of the average bar width) left before each bar.
May be given as a single number or one number per bar. If height is a matrix
and beside is TRUE, space may be specified by two numbers, where the first is
the space between bars in the same group, and the second the space between the
groups. If not given explicitly, it defaults to c(0,1) if height is a matrix and
beside is TRUE, and to 0.2 otherwise.

**names.arg**
a vector of names to be plotted below each bar or group of bars. If this argument
is omitted, then the names are taken from the names attribute of height if this
is a vector, or the column names if it is a matrix.

**legend.text**
a vector of text used to construct a legend for the plot, or a logical indicating
whether a legend should be included. This is only useful when height is a
matrix. In that case given legend labels should correspond to the rows of height;
if legend.text is true, the row names of height will be used as labels if they
are non-null.

**beside**
a logical value. If FALSE, the columns of height are portrayed as stacked bars,
and if TRUE the columns are portrayed as juxtaposed bars.

**horiz**
a logical value. If FALSE, the bars are drawn vertically with the first bar to the
left. If TRUE, the bars are drawn horizontally with the first at the bottom.

**density**
a vector giving the density of shading lines, in lines per inch, for the bars or bar
components. The default value of NULL means that no shading lines are drawn.
Non-positive values of density also inhibit the drawing of shading lines.

**angle**
the slope of shading lines, given as an angle in degrees (counter-clockwise), for
the bars or bar components.

**col**
a vector of colors for the bars or bar components. By default, grey is used if
height is a vector, and a gamma-corrected grey palette if height is a matrix.

**border**
the color to be used for the border of the bars. Use border = NA to omit borders.
If there are shading lines, border = TRUE means use the same colour for the
border as for the shading lines.
main, sub: overall and sub title for the plot.
xlab: a label for the x axis.
ylab: a label for the y axis.
xlim: limits for the x axis.
ylim: limits for the y axis.
xpd: logical. Should bars be allowed to go outside region?
log: string specifying if axis scales should be logarithmic; see plot.default.
axes: logical. If TRUE, a vertical (or horizontal, if horiz is true) axis is drawn.
axisnames: logical. If TRUE, and if there are names.arg (see above), the other axis is drawn (with lty = 0) and labeled.
cex.axis: expansion factor for numeric axis labels.
cex.names: expansion factor for axis names (bar labels).
inside: logical. If TRUE, the lines which divide adjacent (non-stacked!) bars will be drawn. Only applies when space = 0 (which it partly is when beside = TRUE).
plot: logical. If FALSE, nothing is plotted.
axis.lty: the graphics parameter lty applied to the axis and tick marks of the categorical (default horizontal) axis. Note that by default the axis is suppressed.
offset: a vector indicating how much the bars should be shifted relative to the x axis.
add: logical specifying if bars should be added to an already existing plot; defaults to FALSE.
args.legend: list of additional arguments to pass to legend(); names of the list are used as argument names. Only used if legend.text is supplied.
...: arguments to be passed to/from other methods. For the default method these can include further arguments (such as axes, asp and main) and graphical parameters (see par) which are passed to plot.window(), title() and axis.

Details

This is a generic function, it currently only has a default method. A formula interface may be added eventually.

Value

A numeric vector (or matrix, when beside = TRUE), say mp, giving the coordinates of all the bar midpoints drawn, useful for adding to the graph.

If beside is true, use colMeans(mp) for the midpoints of each group of bars, see example.

                       y = c(840, 200) / 840 * 100,
                       z = c(37, 17) / 37 * 100),
        beside = FALSE,
        width = c(465, 840, 37),
        col = c(1, 2),
```
legend.text = c("A", "B"),
args.legend = list(x = "topleft")

box

Description

This function draws a box around the current plot in the given color and linetype. The bty parameter determines the type of box drawn. See par for details.

Usage

box(which = "plot", lty = "solid", ...)

Arguments

which character, one of "plot", "figure", "inner" and "outer".
lty line type of the box.
... further graphical parameters, such as bty, col, or lwd, see par. Note that xpd is not accepted as clipping is always to the device region.

Details

The choice of colour is complicated. If col was supplied and is not NA, it is used. Otherwise, if fg was supplied and is not NA, it is used. The final default is par("col").

References

rect for drawing of arbitrary rectangles.

Examples

plot(1:7, abs(stats::rnorm(7)), type = "h", axes = FALSE)
axis(1, at = 1:7, labels = letters[1:7])
box(lty = "1373", col = "red")
**Description**

Produce box-and-whisker plot(s) of the given (grouped) values.

**Usage**

```r
boxplot(x, ...)  
## S3 method for class 'formula'
boxplot(formula, data = NULL, ..., subset, na.action = NULL,  
       drop = FALSE, sep = ".", lex.order = FALSE)
```

## Default S3 method:

```r
boxplot(x, ..., range = 1.5, width = NULL, varwidth = FALSE,  
       notch = FALSE, outline = TRUE, names, plot = TRUE,  
       border = par("fg"), col = NULL, log = ",",  
       pars = list(boxwex = 0.8, staplewex = 0.5, outwex = 0.5),  
       horizontal = FALSE, add = FALSE, at = NULL)
```

**Arguments**

- `formula` a formula, such as `y ~ grp`, where `y` is a numeric vector of data values to be split into groups according to the grouping variable `grp` (usually a factor).
- `data` a data.frame (or list) from which the variables in `formula` should be taken.
- `subset` an optional vector specifying a subset of observations to be used for plotting.
- `na.action` a function which indicates what should happen when the data contain NAs. The default is to ignore missing values in either the response or the group.
- `drop`, `sep`, `lex.order` passed to `split.default`, see there.
- `x` for specifying data from which the boxplots are to be produced. Either a numeric vector, or a single list containing such vectors. Additional unnamed arguments specify further data as separate vectors (each corresponding to a component boxplot). NAs are allowed in the data.
- `...` For the `formula` method, named arguments to be passed to the default method.
- `range` this determines how far the plot whiskers extend out from the box. If `range` is positive, the whiskers extend to the most extreme data point which is no more than `range` times the interquartile range from the box. A value of zero causes the whiskers to extend to the data extremes.
- `width` a vector giving the relative widths of the boxes making up the plot.
- `varwidth` if `varwidth` is `TRUE`, the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers et al., 1983, p. 62). See boxplot.stats for the calculations used.

if outline is not true, the outliers are not drawn (as points whereas S+ uses lines).

group labels which will be printed under each boxplot. Can be a character vector or an expression (see plotmath).

a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower.

staple line width expansion, proportional to box width.

outlier line width expansion, proportional to box width.

if TRUE (the default) then a boxplot is produced. If not, the summaries which the boxplots are based on are returned.

an optional vector of colors for the outlines of the boxplots. The values in border are recycled if the length of border is less than the number of plots.

if col is non-null it is assumed to contain colors to be used to colour the bodies of the box plots. By default they are in the background colour.

character indicating if x or y or both coordinates should be plotted in log scale.

a list of (potentially many) more graphical parameters, e.g., boxwex or outpch; these are passed to bxp (if plot is true); for details, see there.

logical indicating if the boxplots should be horizontal; default FALSE means vertical boxes.

logical, if true add boxplot to current plot.

numeric vector giving the locations where the boxplots should be drawn, particularly when add = TRUE; defaults to 1:n where n is the number of boxes.

The generic function boxplot currently has a default method (boxplot.default) and a formula interface (boxplot.formula).

If multiple groups are supplied either as multiple arguments or via a formula, parallel boxplots will be plotted, in the order of the arguments or the order of the levels of the factor (see factor).

Missing values are ignored when forming boxplots.

List with the following components:

a matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.

a vector with the number of observations in each group.

a matrix where each column contains the lower and upper extremes of the notch.

the values of any data points which lie beyond the extremes of the whiskers.

a vector of the same length as out whose elements indicate to which group the outlier belongs.

a vector of names for the groups.

boxplot.stats which does the computation, bxp for the plotting and more examples; and stripchart for an alternative (with small data sets).

Examples

## boxplot on a formula:
boxplot(count ~ spray, data = InsectSprays, col = "lightgray")
# *add* notches (somewhat funny here):
boxplot(count ~ spray, data = InsectSprays,
notch = TRUE, add = TRUE, col = "blue")

boxplot(decrease ~ treatment, data = OrchardSprays,
log = "y", col = "bisque")

rb <- boxplot(decrease ~ treatment, data = OrchardSprays, col = "bisque")
title("Comparing boxplot()s and non-robust mean +/- SD")

mn.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, mean)
sd.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, sd)
xi <- 0.3 + seq(rb$n)
points(xi, mn.t, col = "orange", pch = 18)
arrows(xi, mn.t - sd.t, xi, mn.t + sd.t,
    code = 3, col = "pink", angle = 75, length = .1)

## boxplot on a matrix:
mat <- cbind(Uni05 = (1:100)/21, Norm = rnorm(100),
\[\text{t}^{*}\] = rt(100, df = 5), Gam2 = rgamma(100, shape = 2))

boxplot(mat) # directly, calling boxplot.matrix()

## boxplot on a data frame:
df. <- as.data.frame(mat)
par(las = 1) # all axis labels horizontal
boxplot(df., main = "boxplot(*, horizontal = TRUE)", horizontal = TRUE)

## Using 'at = ' and adding boxplots -- example idea by Roger Bivand:
boxplot(len ~ dose, data = ToothGrowth,
boxwex = 0.25, at = 1:3 - 0.2,
subset = supp == "VC", col = "yellow",
main = "Guinea Pigs' Tooth Growth",

xlab = "Vitamin C dose mg",
ylab = "tooth length",
xlim = c(0.5, 3.5), ylim = c(0, 35), yaxs = "i")

boxplot(len ~ dose, data = ToothGrowth, add = TRUE,
boxwex = 0.25, at = 1:3 + 0.2,
subset = supp == "OJ", col = "orange")
legend(2, 9, c("Ascorbic acid", "Orange juice"),
    fill = c("yellow", "orange"))

## With less effort (slightly different) using factor *interaction*:
boxplot(len ~ dose:supp, data = ToothGrowth, 
    boxwex = 0.5, col = c("orange", "yellow"), 
    main = "Guinea Pigs' Tooth Growth", 
    xlab = "Vitamin C dose mg", ylab = "tooth length", 
    sep = ":", lex.order = TRUE, ylim = c(0, 35), yaxs = "i")

## more examples in help(bxp)

---

**boxplot.matrix**

*Draw a Boxplot for each Column (Row) of a Matrix*

**Description**

Interpreting the columns (or rows) of a matrix as different groups, draw a boxplot for each.

**Usage**

```r
## S3 method for class 'matrix'
boxplot(x, use.cols = TRUE, ...)
```

**Arguments**

- `x`: a numeric matrix.
- `use.cols`: logical indicating if columns (by default) or rows (`use.cols = FALSE`) should be plotted.
- `...`: Further arguments to `boxplot`.

**Value**

A list as for `boxplot`.

**Author(s)**

Martin Maechler, 1995, for S+, then R package `sfsmisc`.

**See Also**

- `boxplot.default` which already works nowadays with data.frames;
- `boxplot.formula`, `plot.factor` which work with (the more general concept) of a grouping factor.

**Examples**

```r
## Very similar to the example in ?boxplot
mat <- cbind(Uni05 = (1:100)/21, Norm = rnorm(100), 
    T5 = rt(100, df = 5), Gam2 = rgamma(100, shape = 2))
boxplot(mat, main = "boxplot.matrix(...., main = ...)", 
    notch = TRUE, col = 1:4)
```
Description

bxp draws box plots based on the given summaries in z. It is usually called from within boxplot, but can be invoked directly.

Usage

```r
bxp(z, notch = FALSE, width = NULL, varwidth = FALSE, 
    outline = TRUE, notch.frac = 0.5, log = "", 
    border = par("fg"), pars = NULL, frame.plot = axes, 
    horizontal = FALSE, add = FALSE, at = NULL, show.names = NULL, 
    ...)```

Arguments

- `z`: a list containing data summaries to be used in constructing the plots. These are usually the result of a call to boxplot, but can be generated in any fashion.
- `notch`: if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap then the medians are significantly different at the 5 percent level.
- `width`: a vector giving the relative widths of the boxes making up the plot.
- `varwidth`: if varwidth is TRUE, the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
- `outline`: if outline is not true, the outliers are not drawn.
- `notch.frac`: numeric in (0,1). When notch = TRUE, the fraction of the box width that the notches should use.
- `border`: character or numeric (vector), the color of the box borders. Is recycled for multiple boxes. Is used as default for the boxcol, medcol, whiskcol, staplecol, and outcol options (see below).
- `log`: character, indicating if any axis should be drawn in logarithmic scale, as in plot.default.
- `frame.plot`: logical, indicating if a ‘frame’ (box) should be drawn; defaults to TRUE, unless axes = FALSE is specified.
- `horizontal`: logical indicating if the boxplots should be horizontal; default FALSE means vertical boxes.
- `add`: logical, if true add boxplot to current plot.
- `at`: numeric vector giving the locations where the boxplots should be drawn, particularly when add = TRUE; defaults to 1:n where n is the number of boxes.
- `show.names`: Set to TRUE or FALSE to override the defaults on whether an x-axis label is printed for each group.
- `pars,...`: graphical parameters (etc) can be passed as arguments to this function, either as a list (pars) or normally(...), see the following. (Those in ... take precedence over those in pars.)
Currently, yaxs and ylim are used ‘along the boxplot’, i.e., vertically, when horizontal is false, and xlim horizontally. xaxt, yaxt, las, cex.axis, and col.axis are passed to axis, and main, cex.main, col.main, sub, cex.sub, col.sub, xlab, ylab, cex.lab, and col.lab are passed to title.

In addition, axes is accepted (see plot.window), with default TRUE.

The following arguments (or pars components) allow further customization of the boxplot graphics. Their defaults are typically determined from the non-prefixed version (e.g., boxlty from lty), either from the specified argument or pars component or the corresponding par one.

boxwex: a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower. The default depends on at and typically is 0.8.

staplewex, outwex: staple and outlier line width expansion, proportional to box width; both default to 0.5.

boxlty, boxlwd, boxcol, boxfill: box outline type, width, color, and fill color (which currently defaults to col and will in future default to par(“bg”)).

medlty, medlwd, medpch, medcex, medcol, medbg: median line type, line width, point character, point size expansion, color, and background color. The default medpch = NA suppresses the point, and medlty = “blank” does so for the line. Note that medlwd defaults to 3× the default lwd.

whisklty, whisklwd, whiskcol: whisker line type (default: "dashed"), width, and color.

stapletlty, staplelwd, staplecol: staple (= end of whisker) line type, width, and color.

outlty, outlwd, outpch, outcex, outcol, outbg: outlier line type, line width, point character, point size expansion, color, and background color. The default outlty = “blank” suppresses the lines and outpch = NA suppresses points.

Value

An invisible vector, actually identical to the at argument, with the coordinates ("x" if horizontal is false, "y" otherwise) of box centers, useful for adding to the plot.

Note

When add = FALSE, xlim now defaults to xlim = range(at, *) + c(-0.5, 0.5). It will usually be a good idea to specify xlim if the "x" axis has a log scale or width is far from uniform.

Author(s)

The R Core development team and Arni Magnusson (then at U Washington) who has provided most changes for the box*, med*, whisk*, staple*, and out* arguments.

## too many possibilities
boxplot(z, boxfill = "light gray", outpch = 21:25, outlty = 2,
bg = "pink", lwd = 2,
medcol = "dark blue", medcex = 2, medpch = 20)
Description

Computes and plots conditional densities describing how the conditional distribution of a categori-

cal variable \( y \) changes over a numerical variable \( x \).

Usage

cdplot(x, ...)  

## Default S3 method:  
cdplot(x, y,  
plot = TRUE, tol.ylab = 0.05, ylevels = NULL,  
bw = "nrd0", n = 512, from = NULL, to = NULL,  
col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,  
yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), ...)  

## S3 method for class 'formula'  
cdplot(formula, data = list(),  
plot = TRUE, tol.ylab = 0.05, ylevels = NULL,  
bw = "nrd0", n = 512, from = NULL, to = NULL,  
col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,  
yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), ...,  
subset = NULL)

Arguments

x  
an object, the default method expects a single numerical variable (or an object  
coercible to this).

y  
a "factor" interpreted to be the dependent variable

formula  
a "formula" of type \( y \sim x \) with a single dependent "factor" and a single  
numerical explanatory variable.

data  
an optional data frame.

plot  
logical. Should the computed conditional densities be plotted?

tol.ylab  
convenience tolerance parameter for y-axis annotation. If the distance between  
two labels drops under this threshold, they are plotted equidistantly.

ylevels  
a character or numeric vector specifying in which order the levels of the depen-
dent variable should be plotted.

bw, n, from, to, ...  
arguments passed to \texttt{density}

col  
a vector of fill colors of the same length as \( \text{levels}(y) \). The default is to call  
\texttt{gray.colors}.

border  
border color of shaded polygons.

main, xlab, ylab  
character strings for annotation

yaxlabels  
character vector for annotation of y axis, defaults to \texttt{levels(y)}.

xlim, ylim  
the range of x and y values with sensible defaults.

subset  
an optional vector specifying a subset of observations to be used for plotting.
**Details**

cdplot computes the conditional densities of \(x\) given the levels of \(y\) weighted by the marginal distribution of \(y\). The densities are derived cumulatively over the levels of \(y\).

This visualization technique is similar to spinograms (see spineplot) and plots \(P(y|x)\) against \(x\). The conditional probabilities are not derived by discretization (as in the spinogram), but using a smoothing approach via `density`.

Note, that the estimates of the conditional densities are more reliable for high-density regions of \(x\). Conversely, the are less reliable in regions with only few \(x\) observations.

**Value**

The conditional density functions (cumulative over the levels of \(y\)) are returned invisibly.

```r
## NASA space shuttle o-ring failures
fail <- factor(c(2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1, 1, 2, 1, 2, 1, 1, 1, 1, 2, 1, 2, 1),
               levels = 1:2, labels = c("no", "yes"))
temperature <- c(53, 57, 58, 63, 66, 67, 67, 67, 68, 69, 70, 70, 70, 70, 72, 73, 75, 75, 76, 76, 78, 79, 81)

## CD plot
cdplot(fail ~ temperature)
cdplot(fail ~ temperature, bw = 2)
cdplot(fail ~ temperature, bw = "SJ")

## compare with spinogram
(spineplot(fail ~ temperature, breaks = 3))

## highlighting for failures
cdplot(fail ~ temperature, ylevels = 2:1)

## scatter plot with conditional density
cdens <- cdplot(fail ~ temperature, plot = FALSE)
plot(I(as.numeric(fail) - 1) ~ jitter(temperature, factor = 2),
     xlab = "Temperature", ylab = "Conditional failure probability")
lines(53:81, 1 - cdens[[1]](53:81), col = 2)
```
clip

Set Clipping Region

Description

Set clipping region in user coordinates

Usage

clip(x1, x2, y1, y2)

Arguments

x1, x2, y1, y2 user coordinates of clipping rectangle

Details

How the clipping rectangle is set depends on the setting of par("xpd"): this function changes the current setting until the next high-level plotting command resets it.

Clipping of lines, rectangles and polygons is done in the graphics engine, but clipping of text is if possible done in the device, so the effect of clipping text is device-dependent (and may result in text not wholly within the clipping region being omitted entirely).

Exactly when the clipping region will be reset can be hard to predict. plot.new always resets it. Functions such as lines and text only reset it if par("xpd") has been changed. However, functions such as box, mtext, title and plot.dendrogram can manipulate the xpd setting.

See Also

par

Examples

x <- rnorm(1000)
hist(x, xlim = c(-4,4))
usr <- par("usr")
clip(usr[1], -2, usr[3], usr[4])
hist(x, col = 'red', add = TRUE)
clip(2, usr[2], usr[3], usr[4])
hist(x, col = 'blue', add = TRUE)
do.call("clip", as.list(usr)) # reset to plot region
Description

Create a contour plot, or add contour lines to an existing plot.

Usage

```
contour(x, ...) 
## Default S3 method:
contour(x = seq(0, 1, length.out = nrow(z)),
y = seq(0, 1, length.out = ncol(z)),
z,
nlevels = 10, levels = pretty(zlim, nlevels),
labels = NULL,
xlim = range(x, finite = TRUE),
ylim = range(y, finite = TRUE),
zlim = range(z, finite = TRUE),
labcex = 0.6, drawlabels = TRUE, method = "flattest",
vfont, axes = TRUE, frame.plot = axes,
col = par("fg"), lty = par("lty"), lwd = par("lwd"),
add = FALSE, ...)
```

Arguments

- `x, y` locations of grid lines at which the values in `z` are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If `x` is a list, its components `x$x` and `x$y` are used for `x` and `y`, respectively. If the list has component `z` this is used for `z`.

- `z` a matrix containing the values to be plotted (NAs are allowed). Note that `x` can be used instead of `z` for convenience.

- `nlevels` number of contour levels desired iff `levels` is not supplied.

- `levels` numeric vector of levels at which to draw contour lines.

- `labels` a vector giving the labels for the contour lines. If NULL then the levels are used as labels, otherwise this is coerced by `as.character`.

- `labcex` cex for contour labelling. This is an absolute size, not a multiple of `par("cex")`.

- `drawlabels` logical. Contours are labelled if TRUE.

- `method` character string specifying where the labels will be located. Possible values are "simple", "edge" and "flattest" (the default). See the 'Details' section.

- `vfont` if NULL, the current font family and face are used for the contour labels. If a character vector of length 2 then Hershey vector fonts are used for the contour labels. The first element of the vector selects a typeface and the second element selects a fontindex (see `text` for more information). The default is NULL on graphics devices with high-quality rotation of text and `c("sans serif", "plain")` otherwise.

- `xlim, ylim, zlim` x-, y- and z-limits for the plot.
contour is a generic function with only a default method in base R. The methods for positioning the labels on contours are "simple" (draw at the edge of the plot, overlaying the contour line), "edge" (draw at the edge of the plot, embedded in the contour line, with no labels overlapping) and "flattest" (draw on the flattest section of the contour, embedded in the contour line, with no labels overlapping). The second and third may not draw a label on every contour line.

For information about vector fonts, see the help for text and Hershey. Notice that contour interprets the $z$ matrix as a table of $f(x[i], y[j])$ values, so that the x axis corresponds to row number and the y axis to column number, with column 1 at the bottom, i.e. a 90 degree counter-clockwise rotation of the conventional textual layout.

Alternatively, use contourplot from the lattice package where the formula notation allows to use vectors $x$, $y$, and $z$ of the same length.

There is limited control over the axes and frame as arguments col, lwd and lty refer to the contour lines (rather than being general graphical parameters). For more control, add contours to a plot, or add axes and frame to a contour plot.

options("max.contour.segments") for the maximal complexity of a single contour line. contourlines, filled.contour for color-filled contours, contourplot (and levelplot) from package lattice. Further, image and the graphics demo which can be invoked as demo(graphics).

Examples

```r
require(grDevices) # for colours
x <- -6:16
op <- par(mfrow = c(2, 2))
contour(outer(x, x), method = "edge", vfont = c("sans serif", "plain"))
z <- outer(x, sqrt(abs(x)), FUN = "/")
image(x, x, z)
contour(x, x, z, col = "pink", add = TRUE, method = "edge", vfont = c("sans serif", "plain"))
contour(x, x, z, ylim = c(1, 6), method = "simple", labcex = 1, xlab = quote(x[1]), ylab = quote(x[2]))
contour(x, x, z, ylim = c(-6, 6), nlev = 20, lty = 2, method = "simple",
```
### Convert between Graphics Coordinate Systems

**Description**

Convert between graphics coordinate systems.

**Usage**

- `grconvertX(x, from = "user", to = "user")`
- `grconvertY(y, from = "user", to = "user")`

**Arguments**

- `x, y`: numeric vector of coordinates.
- `from, to`: character strings giving the coordinate systems to convert between.
Details

The coordinate systems are

"user" user coordinates.
"inches" inches.
"device" the device coordinate system.
"ndc" normalized device coordinates.
"nfc" normalized figure coordinates.
"npc" normalized plot coordinates.
"nic" normalized inner region coordinates. (The ‘inner region’ is that inside the outer margins.)

(These names can be partially matched.) For the ‘normalized’ coordinate systems the lower left has value 0 and the top right value 1.

Device coordinates are those in which the device works: they are usually in pixels where that makes sense and in big points (1/72 inch) otherwise (e.g., pdf and postscript).

Value

A numeric vector of the same length as the input.

Examples

```r
op <- par(omd=c(0.1, 0.9, 0.1, 0.9), mfrow = c(1, 2))
plot(1:4)
for(tp in c("in", "dev", "ndc", "nfc", "npc", "nic"))
  print(grconvertX(c(1.0, 4.0), "user", tp))
par(op)
```

Description

This function produces two variants of the conditioning plots discussed in the reference below.

Usage

```r
coplot(formula, data, given.values, panel = points, rows, columns,
       show.given = TRUE, col = par("fg"), pch = par("pch"),
       bar.bg = c(num = gray(0.8), fac = gray(0.95)),
       xlab = c(x.name, paste("Given :", a.name)),
       ylab = c(y.name, paste("Given :", b.name)),
       subscripts = FALSE,
       axlabels = function(f) abbreviate(levels(f)),
       number = 6, overlap = 0.5, xlim, ylim, ...)
co.intervals(x, number = 6, overlap = 0.5)
```
Arguments

formula a formula describing the form of conditioning plot. A formula of the form
\[ y \sim x \mid a \] indicates that plots of \( y \) versus \( x \) should be produced conditional
on the variable \( a \). A formula of the form \( y \sim x \mid a \times b \) indicates that plots of \( y \)
versus \( x \) should be produced conditional on the two variables \( a \) and \( b \).
All three or four variables may be either numeric or factors. When \( x \) or \( y \) are
factors, the result is almost as if \texttt{as.numeric()} was applied, whereas for factor
\( a \) or \( b \), the conditioning (and its graphics if \texttt{show.given} is true) are adapted.
data a data frame containing values for any variables in the formula. By default the
environment where \texttt{coplot} was called from is used.
given.values a value or list of two values which determine how the conditioning on \( a \) and \( b \) is
to take place.
When there is no \( b \) (i.e., conditioning only on \( a \)), usually this is a matrix with
two columns each row of which gives an interval, to be conditioned on, but is
can also be a single vector of numbers or a set of factor levels (if the variable
being conditioned on is a factor). In this case (no \( b \)), the result of \texttt{co.intervals}
can be used directly as \texttt{given.values} argument.
panel a \texttt{function(x, y, col, pch, ...)} which gives the action to be carried out
in each panel of the display. The default is \texttt{points}.
rows the panels of the plot are laid out in a \texttt{rows} by \texttt{columns} array. \texttt{rows} gives the
number of rows in the array.
columns the number of columns in the panel layout array.
show.given logical (possibly of length 2 for 2 conditioning variables): should conditioning
plots be shown for the corresponding conditioning variables (default \texttt{TRUE}).
col a vector of colors to be used to plot the points. If too short, the values are
recycled.
pch a vector of plotting symbols or characters. If too short, the values are recycled.
bar.bg a named vector with components "num" and "fac" giving the background col-
ors for the (shingle) bars, for \texttt{numeric} and \texttt{factor} conditioning variables respec-
tively.
xlab character; labels to use for the x axis and the first conditioning variable. If only
one label is given, it is used for the x axis and the default label is used for the
conditioning variable.
ylab character; labels to use for the y axis and any second conditioning variable.
subscripts logical: if true the panel function is given an additional (third) argument
\texttt{subscripts} giving the subscripts of the data passed to that panel.
axlabels function for creating axis (tick) labels when \( x \) or \( y \) are factors.
number integer; the number of conditioning intervals, for \( a \) and \( b \), possibly of length 2.
It is only used if the corresponding conditioning variable is not a \texttt{factor}.
overlap numeric < 1; the fraction of overlap of the conditioning variables, possibly of
length 2 for \( x \) and \( y \) direction. When overlap < 0, there will be \texttt{gaps} between the
data slices.
xlim the range for the x axis.
ylim the range for the y axis.
... additional arguments to the panel function.
x a numeric vector.
Details

In the case of a single conditioning variable a, when both rows and columns are unspecified, a ‘close to square’ layout is chosen with columns >= rows.

In the case of multiple rows, the order of the panel plots is from the bottom and from the left (corresponding to increasing a, typically).

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus plot and boxplot are not panel functions.

The rendering of arguments xlab and ylab is not controlled by par arguments cex.lab and font.lab even though they are plotted by mtext rather than title.

Value

co.intervals(., number, .) returns a (number × 2) matrix, say ci, where ci[k,] is the range of x values for the k-th interval.

pairs, panel.smooth, points.

Examples

## Tonga Trench Earthquakes
coplot(lat ~ long | depth, data = quakes)
given.depth <- co.intervals(quakes$depth, number = 4, overlap = .1)
coplot(lat ~ long | depth, data = quakes, given.v = given.depth, rows = 1)

## Conditioning on 2 variables:
ll.dm <- lat ~ long | depth * mag
coplot(ll.dm, data = quakes)
coplot(ll.dm, data = quakes, number = c(4, 7), show.given = c(TRUE, FALSE))
coplot(ll.dm, data = quakes, number = c(3, 7),
overlap = c(-.5, .1)) # negative overlap DROPS values

## given two factors
Index <- seq(length = nrow(warpbreaks)) # to get nicer default labels
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
show.given = 0:1)
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
col = "red", bg = "pink", pch = 21,
bar.bg = c(fac = "light blue"))

## Example with empty panels:
with(data.frame(state.x77), {
coplot(Life.Exp ~ Income | Illiteracy * state.region, number = 3,
panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...))

## y ~ factor -- not really sensible, but 'show off'!
coplot(Life.Exp ~ state.region | Income * state.division,
panel = panel.smooth)
curve

))

draws a curve corresponding to a function over the interval [from, to]. curve can plot also an expression in the variable xname, default 'x'.

Usage
curve(expr, from = NULL, to = NULL, n = 101, add = FALSE,
type = "l", xname = "x", xlab = xname, ylab = NULL,
log = NULL, xlim = NULL, ...)  
## S3 method for class 'function'
plot(x, y = 0, to = 1, from = y, xlim = NULL, ylab = NULL, ...)

Arguments

expr The name of a function, or a call or an expression written as a function of x which will evaluate to an object of the same length as x.
x a 'vectorizing' numeric R function.
y alias for from for compatibility with plot
from, to the range over which the function will be plotted.
n integer; the number of x values at which to evaluate.
add logical; if TRUE add to an already existing plot; if NA start a new plot taking the defaults for the limits and log-scaling of the x-axis from the previous plot. Taken as FALSE (with a warning if a different value is supplied) if no graphics device is open.
xlim NULL or a numeric vector of length 2; if non-NULL it provides the defaults for c(from, to) and, unless add = TRUE, selects the x-limits of the plot – see plot.window.
type plot type: see plot.default.
xname character string giving the name to be used for the x axis.
xlab, ylab, log, ... labels and graphical parameters can also be specified as arguments. See 'Details' for the interpretation of the default for log.

Details

The function or expression expr (for curve) or function x (for plot) is evaluated at n points equally spaced over the range [from, to]. The points determined in this way are then plotted.

If either from or to is NULL, it defaults to the corresponding element of xlim if that is not NULL.
What happens when neither from/to nor xlim specifies both x-limits is a complex story. For plot(<function>) and for curve(add = FALSE) the defaults are (0,1). For curve(add = NA) and curve(add = TRUE) the defaults are taken from the x-limits used for the previous plot. (This differs from versions of R prior to 2.14.0.)

The value of log is used both to specify the plot axes (unless add = TRUE) and how ‘equally spaced’ is interpreted: if the x component indicates log-scaling, the points at which the expression or function is plotted are equally spaced on log scale.

The default value of log is taken from the current plot when add = TRUE, whereas if add = NA the x component is taken from the existing plot (if any) and the y component defaults to linear. For add = FALSE the default is ""

This used to be a quick hack which now seems to serve a useful purpose, but can give bad results for functions which are not smooth.

For expensive-to-compute expressions, you should use smarter tools.

The way curve handles expr has caused confusion. It first looks to see if expr is a name (also known as a symbol), in which case it is taken to be the name of a function, and expr is replaced by a call to expr with a single argument with name given by xname. Otherwise it checks that expr is either a call or an expression, and that it contains a reference to the variable given by xname (using all.vars): anything else is an error. Then expr is evaluated in an environment which supplies a vector of name given by xname of length n, and should evaluate to an object of length n. Note that this means that curve(x, ...) is taken as a request to plot a function named x (and it is used as such in the function method for plot).

The plot method can be called directly as plot.function.

Value

A list with components x and y of the points that were drawn is returned invisibly.

Warning

For historical reasons, add is allowed as an argument to the "function" method of plot, but its behaviour may surprise you. It is recommended to use add only with curve.

splinefun for spline interpolation, lines.

Examples

plot(qnorm) # default range c(0, 1) is appropriate here,
# but end values are -/+Inf and so are omitted.
plot(qlogis, main = "The Inverse Logit : qlogis()")
abline(h = 0, v = 0:2/2, lty = 3, col = "gray")

curve(sin, -2*pi, 2*pi, xname = "t")
curve(tan, xname = "t", add = NA,
main = "curve(tan) --> same x-scale as previous plot")

op <- par(mfrow = c(2, 2))
curve(x^2 - 2, col = "violet")
curve(x^2 - 2, add = TRUE, col = "violet")

cos, -pi, 3*pi)
dotchart

curve(cos, xlim = c(-pi, 3*pi), n = 1001, col = "blue", add = TRUE)

chippy <- function(x) sin(cos(x)*exp(-x/2))
curve(chippy, -8, 7, n = 2001)
plot(chippy, -8, -5)

for(ll in c("", "x", "y", "xy"))
  curve(log(1+x), 1, 100, log = ll, sub = paste0("log = ", ll, ","))
par(op)

---

Description

Draw a Cleveland dot plot.

Usage

\[
\text{dotchart}(x, \text{labels} = \text{NULL}, \text{groups} = \text{NULL}, \text{gdata} = \text{NULL},
\text{cex} = \text{par}("cex"), \text{pt.cex} = \text{cex},
\text{pch} = 21, \text{gpch} = 21, \text{bg} = \text{par}("bg"),
\text{color} = \text{par}("fg"), \text{gcolor} = \text{par}("fg"), \text{lcolor} = \text{"gray"},
\text{xlim} = \text{range}(x[\text{is.finite}(x)]),
\text{main} = \text{NULL}, \text{xlab} = \text{NULL}, \text{ylab} = \text{NULL}, \ldots)
\]

Arguments

- \text{x} either a vector or matrix of numeric values (NAs are allowed). If \text{x} is a matrix the overall plot consists of juxtaposed dotplots for each row. Inputs which satisfy \text{is.numeric}(x) but not \text{is.vector}(x) || \text{is.matrix}(x) are coerced by \text{as.numeric}, with a warning.
- \text{labels} a vector of labels for each point. For vectors the default is to use \text{names}(x) and for matrices the row labels \text{dimnames(x)}[[1]].
- \text{groups} an optional factor indicating how the elements of \text{x} are grouped. If \text{x} is a matrix, groups will default to the columns of \text{x}.
- \text{gdata} data values for the groups. This is typically a summary such as the median or mean of each group.
- \text{cex} the character size to be used. Setting \text{cex} to a value smaller than one can be a useful way of avoiding label overlap. Unlike many other graphics functions, this sets the actual size, not a multiple of \text{par}("cex").
- \text{pt.cex} the \text{cex} to be applied to plotting symbols. This behaves like \text{cex} in \text{plot()}.  
- \text{pch} the plotting character or symbol to be used.
- \text{gpch} the plotting character or symbol to be used for group values.
- \text{bg} the background color of plotting characters or symbols to be used; use \text{par}(\text{bg} = \ast) to set the background color of the whole plot.
- \text{color} the color(s) to be used for points and labels.
- \text{gcolor} the single color to be used for group labels and values.
- \text{lcolor} the color(s) to be used for the horizontal lines.
filled.contour

Description

This function produces a contour plot with the areas between the contours filled in solid color (Cleveland calls this a level plot). A key showing how the colors map to \( z \) values is shown to the right of the plot.

Usage

```r
filled.contour(x = seq(0, 1, length.out = nrow(z)),
    y = seq(0, 1, length.out = ncol(z)),
    z,
    xlim = range(x, finite = TRUE),
    ylim = range(y, finite = TRUE),
    zlim = range(z, finite = TRUE),
    levels = pretty(zlim, nlevels), nlevels = 20,
    color.palette = cm.colors,
    col = color.palette(length(levels) - 1),
    plot.title, plot.axes, key.title, key.axes,
    asp = NA, xaxs = "i", yaxs = "i", las = 1,
    axes = TRUE, frame.plot = axes, ...)
```

```
.filled.contour(x, y, z, levels, col)
```
Arguments

- **x, y**
  - Locations of grid lines at which the values in z are measured. These must be in ascending order. (The rest of this description does not apply to `.filled.contour()`. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively. If the list has component z this is used for z.

- **z**
  - A numeric matrix containing the values to be plotted. Note that x can be used instead of z for convenience.

- **xlim**
  - X limits for the plot.

- **ylim**
  - Y limits for the plot.

- **zlim**
  - Z limits for the plot.

- **levels**
  - A set of levels which are used to partition the range of z. Must be strictly increasing (and finite). Areas with z values between consecutive levels are painted with the same color.

- **nlevels**
  - If levels is not specified, the range of z, values is divided into approximately this many levels.

- **color.palette**
  - A color palette function to be used to assign colors in the plot.

- **col**
  - An explicit set of colors to be used in the plot. This argument overrides any palette function specification. There should be one less color than levels.

- **plot.title**
  - Statements which add titles to the main plot.

- **plot.axes**
  - Statements which draw axes (and a box) on the main plot. This overrides the default axes.

- **key.title**
  - Statement which add titles for the plot key.

- **key.axes**
  - Statements which draw axes on the key plot. This overrides the default axes.

- **asp**
  - The y/x aspect ratio, see `plot.window`.

- **xaxs**
  - The x axis style. The default is to use internal labeling.

- **yaxs**
  - The y axis style. The default is to use internal labeling.

- **las**
  - The style of labeling to be used. The default is to use horizontal labeling.

- **axes, frame.plot**
  - Logicals indicating if axes and a box should be drawn, as in `plot.default`.

- **...**
  - Additional graphical parameters, currently only passed to `title()`.

Details

The values to be plotted can contain NAs. Rectangles with two or more corner values are NA are omitted entirely: where there is a single NA value the triangle opposite the NA is omitted.

Values to be plotted can be infinite: the effect is similar to that described for NA values.

`.filled.contour()` is a ‘bare bones’ interface to add just the contour plot to an already-set-up plot region. It is is intended for programmatic use, and the programmer is responsible for checking the conditions on the arguments.

Note

`filled.contour` uses the `layout` function and so is restricted to a full page display.

The output produced by `filled.contour` is actually a combination of two plots; one is the filled contour and one is the legend. Two separate coordinate systems are set up for these two plots, but they are only used internally — once the function has returned these coordinate systems are lost. If you want to annotate the main contour plot, for example to add points, you can specify graphics commands in the `plot.axes` argument. See the examples.
fourfoldplot

Description

Creates a fourfold display of a 2 by 2 by \( k \) contingency table on the current graphics device, allowing for the visual inspection of the association between two dichotomous variables in one or several populations (strata).
fourfoldplot

Usage

```r
fourfoldplot(x, color = c("#99CCFF", "#6699CC"),
conf.level = 0.95,
std = c("margins", "ind.max", "all.max"),
margin = c(1, 2), space = 0.2, main = NULL,
mfrow = NULL, mfcol = NULL)
```

Arguments

- **x**: a 2 by 2 by k contingency table in array form, or as a 2 by 2 matrix if k is 1.
- **color**: a vector of length 2 specifying the colors to use for the smaller and larger diagonals of each 2 by 2 table.
- **conf.level**: confidence level used for the confidence rings on the odds ratios. Must be a single nonnegative number less than 1; if set to 0, confidence rings are suppressed.
- **std**: a character string specifying how to standardize the table. Must match one of "margins", "ind.max", or "all.max", and can be abbreviated to the initial letter. If set to "margins", each 2 by 2 table is standardized to equate the margins specified by `margin` while preserving the odds ratio. If "ind.max" or "all.max", the tables are either individually or simultaneously standardized to a maximal cell frequency of 1.
- **margin**: a numeric vector with the margins to equate. Must be one of 1, 2, or c(1, 2) (the default), which corresponds to standardizing the row, column, or both margins in each 2 by 2 table. Only used if `std` equals "margins".
- **space**: the amount of space (as a fraction of the maximal radius of the quarter circles) used for the row and column labels.
- **main**: character string for the fourfold title.
- **mfrow**: a numeric vector of the form c(nr, nc), indicating that the displays for the 2 by 2 tables should be arranged in an nr by nc layout, filled by rows.
- **mfcol**: a numeric vector of the form c(nr, nc), indicating that the displays for the 2 by 2 tables should be arranged in an nr by nc layout, filled by columns.

Details

The fourfold display is designed for the display of 2 by 2 by k tables.

Following suitable standardization, the cell frequencies $f_{ij}$ of each 2 by 2 table are shown as a quarter circle whose radius is proportional to $\sqrt{f_{ij}}$ so that its area is proportional to the cell frequency. An association (odds ratio different from 1) between the binary row and column variables is indicated by the tendency of diagonally opposite cells in one direction to differ in size from those in the other direction; color is used to show this direction. Confidence rings for the odds ratio allow a visual test of the null of no association; the rings for adjacent quadrants overlap if and only if the observed counts are consistent with the null hypothesis.

Typically, the number k corresponds to the number of levels of a stratifying variable, and it is of interest to see whether the association is homogeneous across strata. The fourfold display visualizes the pattern of association. Note that the confidence rings for the individual odds ratios are not adjusted for multiple testing.

fourfoldplot(x)

## Fourfold display of x, with frequencies in each table
## standardized to equate the margins for admission. but not
## for sex.
## Figure 3 in Friendly (1994).
fourfoldplot(x, margin = 2)

frame

Create / Start a New Plot Frame

Description

This function (frame is an alias for plot.new) causes the completion of plotting in the current plot
(if there is one) and an advance to a new graphics frame. This is used in all high-level plotting
functions and also useful for skipping plots when a multi-figure region is in use.

Usage

plot.new()
frame()

Details

The new page is painted with the background colour (par("bg")), which is often transparent. For
devices with a canvas colour (the on-screen devices X11, windows and quartz), the window is first
painted with the canvas colour and then the background colour.

There are two hooks called "before.plot.new" and "plot.new" (see setHook) called immedi-
ately before and after advancing the frame. The latter is used in the testing code to annotate the new
page. The hook function(s) are called with no argument. (If the value is a character string, get is
called on it from within the graphics namespace.)
grid

Add Grid to a Plot

Description

grid adds an nx by ny rectangular grid to an existing plot.

Usage

grid(nx = NULL, ny = nx, col = "lightgray", lty = "dotted", lwd = par("lwd"), equilogs = TRUE)

Arguments

- nx, ny: number of cells of the grid in x and y direction. When NULL, as per default, the grid aligns with the tick marks on the corresponding default axis (i.e., tickmarks as computed by `axTicks`). When NA, no grid lines are drawn in the corresponding direction.
- col: character or (integer) numeric; color of the grid lines.
- lty: character or (integer) numeric; line type of the grid lines.
- lwd: non-negative numeric giving line width of the grid lines.
- equilogs: logical, only used when log coordinates and alignment with the axis tick marks are active. Setting equilogs = FALSE in that case gives non equidistant tick aligned grid lines.

Note

If more fine tuning is required, use `abline(h = ., v = .)` directly.

References

See Also

plot, abline, lines, points.
Examples

```r
plot(1:3)
grid(NA, 5, lwd = 2) # grid only in y-direction
```

```r
## maybe change the desired number of tick marks: par(lab = c(mx, my, 7))
op <- par(mfcol = 1:2)
with(iris, 
  {
    plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
         xlim = c(4, 8), ylim = c(2, 4.5), panel.first = grid(),
         main = "with(iris, plot(...., panel.first = grid(), ..) )")
    plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
         panel.first = grid(3, lty = 1, lwd = 2),
         main = "... panel.first = grid(3, lty = 1, lwd = 2), ..")
  }
)
par(op)
```
• a function to compute the number of cells.

In the last three cases the number is a suggestion only; as the breakpoints will be set to pretty values, the number is limited to 1e6 (with a warning if it was larger). If breaks is a function, the x vector is supplied to it as the only argument (and the number of breaks is only limited by the amount of available memory).

freq logical; if TRUE, the histogram graphic is a representation of frequencies, the counts component of the result; if FALSE, probability densities, component density, are plotted (so that the histogram has a total area of one). Defaults to TRUE if and only if breaks are equidistant (and probability is not specified).

probability an alias for !freq, for S compatibility.

include.lowest logical; if TRUE, an x[i] equal to the breaks value will be included in the first (or last, for right = FALSE) bar. This will be ignored (with a warning) unless breaks is a vector.
right logical; if TRUE, the histogram cells are right-closed (left open) intervals.

density the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. Non-positive values of density also inhibit the drawing of shading lines.

angle the slope of shading lines, given as an angle in degrees (counter-clockwise).

col a colour to be used to fill the bars. The default of NULL yields unfilled bars.

border the color of the border around the bars. The default is to use the standard foreground color.

main, xlab, ylab these arguments to title have useful defaults here.

xlim, ylim the range of x and y values with sensible defaults. Note that xlim is not used to define the histogram (breaks), but only for plotting (when plot = TRUE).

axes logical. If TRUE (default), axes are draw if the plot is drawn.

plot logical. If TRUE (default), a histogram is plotted, otherwise a list of breaks and counts is returned. In the latter case, a warning is used if (typically graphical) arguments are specified that only apply to the plot = TRUE case.

labels logical or character string. Additionally draw labels on top of bars, if not FALSE; see plot.histogram.

nclass numeric (integer). For S(-PLUS) compatibility only, nclass is equivalent to breaks for a scalar or character argument.

warn.unused logical. If plot = FALSE and warn.unused = TRUE, a warning will be issued when graphical parameters are passed to hist.default().

... further arguments and graphical parameters passed to plot.histogram and thence to title and axis (if plot = TRUE).

Details

The definition of histogram differs by source (with country-specific biases). R’s default with equi-spaced breaks (also the default) is to plot the counts in the cells defined by breaks. Thus the height of a rectangle is proportional to the number of points falling into the cell, as is the area provided the breaks are equally-spaced.

The default with non-equi-spaced breaks is to give a plot of area one, in which the area of the rectangles is the fraction of the data points falling in the cells.
If `right = TRUE` (default), the histogram cells are intervals of the form \((a, b]\), i.e., they include their right-hand endpoint, but not their left one, with the exception of the first cell when `include.lowest` is `TRUE`.

For `right = FALSE`, the intervals are of the form \([a, b)\), and `include.lowest` means 'include highest'.

A numerical tolerance of \(10^{-7}\) times the median bin size (for more than four bins, otherwise the median is substituted) is applied when counting entries on the edges of bins. This is not included in the reported breaks nor in the calculation of density.

The default for `breaks` is "Sturges": see `nclass.Sturges`. Other names for which algorithms are supplied are "Scott" and "FD" / "Freedman-Diaconis" (with corresponding functions `nclass.scott` and `nclass.FD`). Case is ignored and partial matching is used. Alternatively, a function can be supplied which will compute the intended number of breaks or the actual breakpoints as a function of \(x\).

Value

an object of class "histogram" which is a list with components:

- `breaks` the \(n + 1\) cell boundaries (= `breaks` if that was a vector). These are the nominal breaks, not with the boundary fuzz.
- `counts` \(n\) integers; for each cell, the number of \(x[\] inside.
- `density` values \(\hat{f}(x_i)\), as estimated density values. If \(\text{all}(\text{diff(breaks)} == 1)\), they are the relative frequencies \(\text{counts}/n\) and in general satisfy \(\sum_i \hat{f}(x_i)(b_{i+1} - b_i) = 1\), where \(b_i = \text{breaks}[i]\).
- `mids` the \(n\) cell midpoints.
- `xname` a character string with the actual \(x[]\) argument name.
- `equidist` logical, indicating if the distances between `breaks` are all the same.

References

See Also

`nclass.Sturges`, `stem`, `density`, `truehist` in package MASS.

Typical plots with vertical bars are not histograms. Consider `barplot` or `plot(*, type = "h")` for such bar plots.

Examples

```r
op <- par(mfrow = c(2, 2))
hist(islands)
utils::str(hist(islands, col = "gray", labels = TRUE))

hist(sort(islands), breaks = 12, col = "lightblue", border = "pink")
##-- For non-equidistant breaks, counts should NOT be graphed unscaled:
r <- hist(sort(islands), breaks = c(4*0:5, 10*3:5, 70, 100, 140),
          col = "blue1")
text(r$mids, r$density, r$counts, adj = c(.5, -.5), col = "blue3")
```
### hist.POSIXt

**Histogram of a Date or Date-Time Object**

**Description**

Method for `hist` applied to date or date-time objects.

**Usage**

```r
## S3 method for class 'POSIXt'
hist(x, breaks, ..., 
  xlab = deparse(substitute(x)),
  plot = TRUE, freq = FALSE,
  start.on.monday = TRUE, format, right = TRUE)
```

```r
## S3 method for class 'Date'
hist(x, breaks, ..., 
  xlab = deparse(substitute(x)),
  plot = TRUE, freq = FALSE,
  start.on.monday = TRUE, format, right = TRUE)
```
Arguments

x an object inheriting from class "POSIXt" or "Date".
breaks a vector of cut points or number giving the number of intervals which x is to be cut into or an interval specification, one of "days", "weeks", "months", "quarters" or "years", plus "secs", "mins", "hours" for date-time objects.

... graphical parameters, or arguments to hist.default such as include.lowest, right and labels.
xlab a character string giving the label for the x axis, if plotted.
plot logical. If TRUE (default), a histogram is plotted, otherwise a list of breaks and counts is returned.
freq logical; if TRUE, the histogram graphic is a representation of frequencies, i.e, the counts component of the result; if FALSE, relative frequencies (probabilities) are plotted.

start.on.monday logical. If breaks = "weeks", should the week start on Mondays or Sundays?

format for the x-axis labels. See strftime.
right logical; if TRUE, the histogram cells are right-closed (left open) intervals.

Details

Note that unlike the default method, breaks is a required argument.
Using breaks = "quarters" will create intervals of 3 calendar months, with the intervals beginning on January 1, April 1, July 1 or October 1, based upon min(x) as appropriate.
With the default right = TRUE, breaks will be set on the last day of the previous period when breaks is "months", "quarters" or "years". Use right = FALSE to set them to the first day of the interval shown in each bar.

Value

An object of class "histogram": see hist.

rug(.leap.seconds, lwd=2)

## 100 random dates in a 10-week period
random.dates <- as.Date("2001/1/1") + 70*stats::runif(100)
hist(random.dates, "weeks", format = "%d %b")
Identify Points in a Scatter Plot

Description

identify reads the position of the graphics pointer when the (first) mouse button is pressed. It then searches the coordinates given in x and y for the point closest to the pointer. If this point is close enough to the pointer, its index will be returned as part of the value of the call.

Usage

identify(x, ...)

## Default S3 method:
identify(x, y = NULL, labels = seq_along(x), pos = FALSE,
n = length(x), plot = TRUE, atpen = FALSE, offset = 0.5,
tolerance = 0.25, ...)

Arguments

x, y coordinates of points in a scatter plot. Alternatively, any object which defines coordinates (a plotting structure, time series etc: see xy.coords) can be given as x, and y left missing.

labels an optional character vector giving labels for the points. Will be coerced using as.character, and recycled if necessary to the length of x. Excess labels will be discarded, with a warning.

pos if pos is TRUE, a component is added to the return value which indicates where text was plotted relative to each identified point: see Value.

n the maximum number of points to be identified.

plot logical: if plot is TRUE, the labels are printed near the points and if FALSE they are omitted.

atpen logical: if TRUE and plot = TRUE, the lower-left corners of the labels are plotted at the points clicked rather than relative to the points.

offset the distance (in character widths) which separates the label from identified points. Negative values are allowed. Not used if atpen = TRUE.

tolerance the maximal distance (in inches) for the pointer to be ‘close enough’ to a point.

... further arguments passed to par such as cex, col and font.

Details

identify is a generic function, and only the default method is described here.

identify is only supported on screen devices such as X11, windows and quartz. On other devices the call will do nothing.

Clicking near (as defined by tolerance) a point adds it to the list of identified points. Points can be identified only once, and if the point has already been identified or the click is not near any of the points a message is printed immediately on the R console.

If plot is TRUE, the point is labelled with the corresponding element of labels. If atpen is false (the default) the labels are placed below, to the left, above or to the right of the identified point,
depending on where the pointer was relative to the point. If atpen is true, the labels are placed with the bottom left of the string’s box at the pointer.

For the usual X11 device the identification process is terminated by pressing any mouse button other than the first. For the quartz device the process is terminated by pressing either the pop-up menu equivalent (usually second mouse button or Ctrl-click) or the ESC key.

On most devices which support identify, successful selection of a point is indicated by a bell sound unless options(locatorBell = FALSE) has been set.

If the window is resized or hidden and then exposed before the identification process has terminated, any labels drawn by identify will disappear. These will reappear once the identification process has terminated and the window is resized or hidden and exposed again. This is because the labels drawn by identify are not recorded in the device’s display list until the identification process has terminated.

If you interrupt the identify call this leaves the graphics device in an undefined state, with points labelled but labels not recorded in the display list. Copying a device in that state will give unpredictable results.

Value

If pos is FALSE, an integer vector containing the indices of the identified points, in the order they were identified.

If pos is TRUE, a list containing a component ind, indicating which points were identified and a component pos, indicating where the labels were placed relative to the identified points (1=below, 2=left, 3=above, 4=right and 0=no offset, used if atpen = TRUE).

Technicalities

The algorithm used for placing labels is the same as used by text if pos is specified there, the difference being that the position of the pointer relative the identified point determines pos in identify.

For labels placed to the left of a point, the right-hand edge of the string’s box is placed offset units to the left of the point, and analogously for points to the right. The baseline of the text is placed below the point so as to approximately centre string vertically. For labels placed above or below a point, the string is centered horizontally on the point. For labels placed above, the baseline of the text is placed offset units above the point, and for those placed below, the baseline is placed so that the top of the string’s box is approximately offset units below the point. If you want more precise placement (e.g., centering) use plot = FALSE and plot via text or points: see the examples.

Examples

```r
## A function to use identify to select points, and overplot the
## points with another symbol as they are selected
identifyPch <- function(x, y = NULL, n = length(x), plot = FALSE, pch = 19, ...)
{
```
xy <- xy.coords(x, y); x <- xy$x; y <- xy$y
sel <- rep(FALSE, length(x))
while(sum(sel) < n) {
    ans <- identify(x[!sel], y[!sel], labels = which(!sel), n = 1, plot = plot, ...)
    if(!length(ans)) break
    ans <- which(!sel)[ans]
    points(x[ans], y[ans], pch = pch)
    sel[ans] <- TRUE
}
## return indices of selected points
which(sel)

if(dev.interactive()) { ## use it
    x <- rnorm(50); y <- rnorm(50)
    plot(x,y); identifyPch(x,y) # how fast to get all?
}

---

**image**

*Display a Color Image*

**Description**

Creates a grid of colored or gray-scale rectangles with colors corresponding to the values in \( z \). This can be used to display three-dimensional or spatial data aka \textit{images}. This is a generic function.

The functions \texttt{heat.colors}, \texttt{terrain.colors} and \texttt{topo.colors} create heat-spectrum (red to white) and topographical color schemes suitable for displaying ordered data, with \( n \) giving the number of colors desired.

**Usage**

\texttt{image(x, \ldots)}

### Default S3 method:

\texttt{image(x, y, z, zlim, xlim, ylim, col = heat.colors(12),
add = FALSE, xaxs = "i", yaxs = "i", xlab, ylab,
breaks, oldstyle = FALSE, useRaster, \ldots)}

**Arguments**

\texttt{x, y} \quad \text{name} for \texttt{x} \quad \text{name} for \texttt{y}

locations of grid lines at which the values in \( z \) are measured. These must be finite, non-missing and in (strictly) ascending order. By default, equally spaced values from 0 to 1 are used. If \( x \) is a list, its components \( x$x \) and \( x$y \) are used for \( x \) and \( y \), respectively. If the list has component \( z \) this is used for \( z \).

\texttt{z} \quad \text{name} for \texttt{z}

a numeric or logical matrix containing the values to be plotted (NAs are allowed). Note that \( x \) can be used instead of \( z \) for convenience.

\texttt{zlim} \quad \text{name} for \texttt{zlim}

the minimum and maximum \( z \) values for which colors should be plotted, defaulting to the range of the finite values of \( z \). Each of the given colors will be used to color an equispaced interval of this range. The \texttt{midpoints} of the intervals cover the range, so that values just outside the range will be plotted.
xlim, ylim  ranges for the plotted x and y values, defaulting to the ranges of x and y.
col  a list of colors such as that generated by rainbow, heat.colors, topo.colors, terrain.colors or similar functions.
add  logical; if TRUE, add to current plot (and disregard the following four arguments). This is rarely useful because image ‘paints’ over existing graphics.
xaxs, yaxs  style of x and y axis. The default “i” is appropriate for images. See par.
xlab, ylab  each a character string giving the labels for the x and y axis. Default to the ‘call names’ of x or y, or to “” if these were unspecified.
breaks  a set of finite numeric breakpoints for the colours: must have one more breakpoint than colour and be in increasing order. Unsorted vectors will be sorted, with a warning.
oldstyle  logical. If true the midpoints of the colour intervals are equally spaced, and zlim[1] and zlim[2] were taken to be midpoints. The default is to have colour intervals of equal lengths between the limits.
useRaster  logical; if TRUE a bitmap raster is used to plot the image instead of polygons. The grid must be regular in that case, otherwise an error is raised. For the behaviour when this is not specified, see ‘Details’.
...

Details

The length of x should be equal to the nrow(z)+1 or nrow(z). In the first case x specifies the boundaries between the cells: in the second case x specifies the midpoints of the cells. Similar reasoning applies to y. It probably only makes sense to specify the midpoints of an equally-spaced grid. If you specify just one row or column and a length-one x or y, the whole user area in the corresponding direction is filled. For logarithmic x or y axes the boundaries between cells must be specified.

Rectangles corresponding to missing values are not plotted (and so are transparent and (unless add = TRUE) the default background painted in par("bg") will show through and if that is transparent, the canvas colour will be seen).

If breaks is specified then zlim is unused and the algorithm used follows cut, so intervals are closed on the right and open on the left except for the lowest interval which is closed at both ends.

The axes (where plotted) make use of the classes of xlim and ylim (and hence by default the classes of x and y): this will mean that for example dates are labelled as such.

Notice that image interprets the z matrix as a table of f(x[i], y[j]) values, so that the x axis corresponds to row number and the y axis to column number, with column 1 at the bottom, i.e. a 90 degree counter-clockwise rotation of the conventional printed layout of a matrix.

Images for large z on a regular grid are rendered more efficiently with useRaster = TRUE and can prevent rare anti-aliasing artifacts, but may not be supported by all graphics devices. Some devices (such as postscript and X11(type = "Xlib")) which do not support semi-transparent colours may emit missing values as white rather than transparent, and there may be limitations on the size of a raster image. (Problems with the rendering of raster images have been reported by users of windows() devices under Remote Desktop, at least under its default settings.)

The graphics files in PDF and PostScript can be much smaller under this option.

If useRaster is not specified, raster images are used when thegetOption("preferRaster") is true, the grid is regular and either dev.capabilities("rasterImage")$rasterImage is "yes" or it is "non-missing" and there are no missing values.
Note

Originally based on a function by Thomas Lumley.

axis(2, at = seq(100, 600, by = 100))
box()
title(main = "Maunga Whau Volcano", font.main = 4)

Description

layout divides the device up into as many rows and columns as there are in matrix mat, with the column-widths and the row-heights specified in the respective arguments.

Usage

layout(mat, widths = rep.int(1, ncol(mat)),
  heights = rep.int(1, nrow(mat)), respect = FALSE)
layout.show(n = 1)
lcm(x)
Arguments

mat  a matrix object specifying the location of the next $N$ figures on the output device. Each value in the matrix must be 0 or a positive integer. If $N$ is the largest positive integer in the matrix, then the integers $\{1, \ldots, N-1\}$ must also appear at least once in the matrix.

widths  a vector of values for the widths of columns on the device. Relative widths are specified with numeric values. Absolute widths (in centimetres) are specified with the lcm() function (see examples).

heights  a vector of values for the heights of rows on the device. Relative and absolute heights can be specified, see widths above.

respect  either a logical value or a matrix object. If the latter, then it must have the same dimensions as mat and each value in the matrix must be either 0 or 1.

n  number of figures to plot.

x  a dimension to be interpreted as a number of centimetres.

Details

Figure $i$ is allocated a region composed from a subset of these rows and columns, based on the rows and columns in which $i$ occurs in mat.

The respect argument controls whether a unit column-width is the same physical measurement on the device as a unit row-height.

There is a limit (currently 200) for the numbers of rows and columns in the layout, and also for the total number of cells (10007).

layout.show(n) plots (part of) the current layout, namely the outlines of the next $n$ figures.

lcm is a trivial function, to be used as the interface for specifying absolute dimensions for the widths and heights arguments of layout().

Value

layout returns the number of figures, $N$, see above.

Warnings

These functions are totally incompatible with the other mechanisms for arranging plots on a device: par(mfrow), par(mfcol) and split.screen.

**legend**

Add Legends to Plots

Description

This function can be used to add legends to plots. Note that a call to the function `locator(1)` can be used in place of the `x` and `y` arguments.

Usage

```r
legend(x, y = NULL, legend, fill = NULL, col = par("col"),
       border = "black", lty, lwd, pch,
```
angle = 45, density = NULL, bty = "o", bg = par("bg"),
box.lwd = par("lwd"), box.lty = par("lty"), box.col = par("fg"),
pt.bg = NA, cex = 1, pt.cex = cex, pt.lwd = lwd,
xjust = 0, yjust = 1, x.intersp = 1, y.intersp = 1,
adj = c(0, 0.5), text.width = NULL, text.col = par("col"),
text.font = NULL, merge = do.lines && has.pch, trace = FALSE,
plot = TRUE, ncol = 1, horiz = FALSE, title = NULL,
inset = 0, xpd, title.col = text.col, title.adj = 0.5,
seg.len = 2)

Arguments

x, y
the x and y co-ordinates to be used to position the legend. They can be specified
by keyword or in any way which is accepted by xy.coords: See 'Details'.

legend
a character or expression vector of length ≥ 1 to appear in the legend. Other
objects will be coerced by as.graphicsAnnot.

fill
if specified, this argument will cause boxes filled with the specified colors (or
shaded in the specified colors) to appear beside the legend text.

col
the color of points or lines appearing in the legend.

border
the border color for the boxes (used only if fill is specified).

lty, lwd
the line types and widths for lines appearing in the legend. One of these two
must be specified for line drawing.

pch
the plotting symbols appearing in the legend, as numeric vector or a vector of
1-character strings (see points). Unlike points, this can all be specified as a
single multi-character string. Must be specified for symbol drawing.

angle
angle of shading lines.

density
the density of shading lines, if numeric and positive. If NULL or negative or NA
color filling is assumed.

bty
the type of box to be drawn around the legend. The allowed values are "o" (the
default) and "n".

bg
the background color for the legend box. (Note that this is only used if
bty != "n").

box.lty, box.lwd, box.col
the line type, width and color for the legend box (if bty = "o").

pt.bg
the background color for the points, corresponding to its argument bg.

cex
character expansion factor relative to current par("cex"). Used for text, and
provides the default for pt.cex.

pt.cex
expansion factor(s) for the points.

pt.lwd
line width for the points, defaults to the one for lines, or if that is not set, to
par("lwd").

xjust
how the legend is to be justified relative to the legend x location. A value of 0
means left justified, 0.5 means centered and 1 means right justified.

yjust
the same as xjust for the legend y location.

x.intersp
character interspacing factor for horizontal (x) spacing.

y.intersp
the same for vertical (y) line distances.

adj
numeric of length 1 or 2; the string adjustment for legend text. Useful for y-
adjustment when labels are plotmath expressions.
**legend**

The `legend()` function is used to add a legend to a plot. It takes several arguments:

- **text.width**: The width of the legend text in x ("user") coordinates. (Should be a single positive number even for a reversed x axis.) Defaults to the proper value computed by `strwidth(legend)`.
- **text.col**: The color used for the legend text.
- **text.font**: The font used for the legend text, see `text`.
- **merge**: Logical; if TRUE, merge points and lines but not filled boxes. Defaults to TRUE if there are points and lines.
- **trace**: Logical; if TRUE, shows how `legend` does all its magical computations.
- **plot**: Logical. If FALSE, nothing is plotted but the sizes are returned.
- **ncol**: The number of columns in which to set the legend items (default is 1, a vertical legend).
- **horiz**: Logical; if TRUE, set the legend horizontally rather than vertically (specifying `horiz` overrides the `ncol` specification).
- **title**: A character string or length-one expression giving a title to be placed at the top of the legend. Other objects will be coerced by `as.graphicsAnnot`.
- **inset**: Inset distance(s) from the margins as a fraction of the plot region when legend is placed by keyword.
- **xpd**: If supplied, a value of the graphical parameter `xpd` to be used while the legend is being drawn.
- **title.col**: Color for `title`.
- **title.adj**: Horizontal adjustment for `title`: see the help for `par("adj")`.
- **seg.len**: The length of lines drawn to illustrate `lty` and/or `lwd` (in units of character widths).

**Details**

Arguments `x`, `y`, `legend` are interpreted in a non-standard way to allow the coordinates to be specified via one or two arguments. If `legend` is missing and `y` is not numeric, it is assumed that the second argument is intended to be `legend` and that the first argument specifies the coordinates.

The coordinates can be specified in any way which is accepted by `xy.coords`. If this gives the coordinates of one point, it is used as the top-left coordinate of the rectangle containing the legend. If it gives the coordinates of two points, these specify opposite corners of the rectangle (either pair of corners, in any order).

The location may also be specified by setting `x` to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the legend on the inside of the plot frame at the given location. Partial argument matching is used. The optional `inset` argument specifies how far the legend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for `x`-distance, the second for `y`-distance.

Attribute arguments such as `col`, `pch`, `lty`, etc, are recycled if necessary: `merge` is not. Set entries of `lty` to 0 or set entries of `lwd` to `NA` to suppress lines in corresponding legend entries; set `pch` values to `NA` to suppress points.

Points are drawn after lines in order that they can cover the line with their background color `pt.bg`, if applicable.

See the examples for how to right-justify labels.

Since they are not used for Unicode code points, values `−31:−1` are silently omitted, as are `NA` and `""` values.
Value

A list with list components

- **rect**: a list with components
  - \(w, h\): positive numbers giving \textbf{width} and \textbf{height} of the legend’s box.
  - \(\text{left}, \text{top}\): \(x\) and \(y\) coordinates of upper left corner of the box.

- **text**: a list with components
  - \(x, y\): numeric vectors of length \text{length(legend)}\, giving the \(x\) and \(y\) coordinates of the legend’s text(s).

Note: \text{rect} and \text{text} are returned invisibly.

  x = seq(-pi, pi, len = 65),
  plot(x, sin(x), type = "l", col = 2, xlab = expression(phi),
       ylab = expression(f(x))),
  abline(h = -1:1, v = pi/2*(-6:6), col = "gray90")
)
```

```r
ex.cs1 <- expression(plain(sin) * x, paste("cos", x))
utils::str(legend(-3, .9, ex.cs1, lty = 1:2, plot = FALSE, adj = c(0, 0.6)))
```

```r
ex12 <- expression(bar(x) == sum(over(x[i], n), i == 1, n),
                    hat(x) == median(x[i], i == 1, n))
utils::str(legend(4.1, 30, ex12, col = 2:3, lty = 2:3, lwd = 2))
```
Add Connected Line Segments to a Plot

Description

A generic function taking coordinates given in various ways and joining the corresponding points with line segments.

Usage

lines(x, ...)

## Default S3 method:
lines(x, y = NULL, type = "l", ...)
Arguments

- **x, y**: coordinate vectors of points to join.
- **type**: character indicating the type of plotting; actually any of the types as in `plot.default`.
- **...**: Further graphical parameters (see `par`) may also be supplied as arguments, particularly, line type, `lty`, line width, `lwd`, color, `col` and for `type = "b"`, `pch`. Also the line characteristics `lend`, `ljoin` and `lmitre`.

Details

The coordinates can be passed in a plotting structure (a list with `x` and `y` components), a two-column matrix, a time series, ... See `xy.coords`. If supplied separately, they must be of the same length.

The coordinates can contain NA values. If a point contains NA in either its `x` or `y` value, it is omitted from the plot, and lines are not drawn to or from such points. Thus missing values can be used to achieve breaks in lines.

For `type = "h"`, `col` can be a vector and will be recycled as needed.

`lwd` can be a vector: its first element will apply to lines but the whole vector to symbols (recycled as necessary).

- `lines.formula` for the formula method; `points`, particularly for `type %in% c("p","b","o")`, `plot`, and the workhorse function `plot.xy`.
- `abline` for drawing (single) straight lines.
- `par` for line type (`lty`) specification and how to specify colors.

Examples

```r
# draw a smooth line through a scatter plot
plot(cars, main = "Stopping Distance versus Speed")
lines(stats::lowess(cars))
```

Description

Reads the position of the graphics cursor when the (first) mouse button is pressed.

Usage

```
locator(n = 512, type = "n", ...)
```
Arguments

- **n**  
  the maximum number of points to locate. Valid values start at 1.

- **type**  
  One of "n", "p", "l" or "o". If "p" or "o" the points are plotted; if "l" or "o" they are joined by lines.

- **...**  
  additional graphics parameters used if type != "n" for plotting the locations.

Details

`locator` is only supported on screen devices such as X11, windows and quartz. On other devices the call will do nothing.

Unless the process is terminated prematurely by the user (see below) at most n positions are determined.

For the usual X11 device the identification process is terminated by pressing any mouse button other than the first. For the quartz device the process is terminated by pressing the ESC key.

The current graphics parameters apply just as if `plot.default` has been called with the same value of type. The plotting of the points and lines is subject to clipping, but locations outside the current clipping rectangle will be returned.

On most devices which support `locator`, successful selection of a point is indicated by a bell sound unless `options(locatorBell = FALSE)` has been set.

If the window is resized or hidden and then exposed before the input process has terminated, any lines or points drawn by `locator` will disappear. These will reappear once the input process has terminated and the window is resized or hidden and exposed again. This is because the points and lines drawn by `locator` are not recorded in the device’s display list until the input process has terminated.

Value

A list containing x and y components which are the coordinates of the identified points in the user coordinate system, i.e., the one specified by `par("usr")`.

---

**matplot**  
*Plot Columns of Matrices*

Description

Plot the columns of one matrix against the columns of another.
Usage

\texttt{matplot(x, y, type = "p", lty = 1:5, lwd = 1, lend = par("lend"),}
  \hspace{1cm} pch = \text{NULL},
  \hspace{1cm} col = 1:6, cex = \text{NULL}, bg = \text{NA},
  \hspace{1cm} xlab = \text{NULL}, ylab = \text{NULL}, xlim = \text{NULL}, ylim = \text{NULL},
  \hspace{1cm} \ldots, add = \text{FALSE}, verbose = getOption("verbose"))

\texttt{matpoints(x, y, type = "p", lty = 1:5, lwd = 1, pch = \text{NULL},}
  \hspace{1cm} col = 1:6, \ldots)

\texttt{matlines (x, y, type = "l", lty = 1:5, lwd = 1, pch = \text{NULL},}
  \hspace{1cm} col = 1:6, \ldots)

Arguments

- **x, y**: vectors or matrices of data for plotting. The number of rows should match. If one of them are missing, the other is taken as y and an x vector of \(1:n\) is used. Missing values (\text{NA}s) are allowed.
- **type**: character string (length 1 vector) or vector of 1-character strings indicating the type of plot for each column of y, see \texttt{plot} for all possible types. The first character of type defines the first plot, the second character the second, etc. Characters in type are cycled through; e.g., "pl" alternately plots points and lines.
- **lty, lwd, lend**: vector of line types, widths, and end styles. The first element is for the first column, the second element for the second column, etc., even if lines are not plotted for all columns. Line types will be used cyclically until all plots are drawn.
- **pch**: character string or vector of 1-characters or integers for plotting characters, see \texttt{points}. The first character is the plotting-character for the first plot, the second for the second, etc. The default is the digits (1 through 9, 0) then the lowercase and uppercase letters.
- **col**: vector of colors. Colors are used cyclically.
- **cex**: vector of character expansion sizes, used cyclically. This works as a multiple of \texttt{par("cex")}. \text{NULL} is equivalent to 1.0.
- **bg**: vector of background (fill) colors for the open plot symbols given by \texttt{pch = 21:25} as in \texttt{points}. The default \text{NA} corresponds to the one of the underlying function \texttt{plot.xy}.
- **xlab, ylab**: titles for x and y axes, as in \texttt{plot}.
- **xlim, ylim**: ranges of x and y axes, as in \texttt{plot}.
- **\ldots**: Graphical parameters (see \texttt{par}) and any further arguments of \texttt{plot}, typically \texttt{plot.default}, may also be supplied as arguments to this function. Hence, the high-level graphics control arguments described under \texttt{par} and the arguments to \texttt{title} may be supplied to this function.
- **add**: logical. If \text{TRUE}, plots are added to current one, using \texttt{points} and \texttt{lines}.
- **verbose**: logical. If \text{TRUE}, write one line of what is done.

Details

Points involving missing values are not plotted.
The first column of \( x \) is plotted against the first column of \( y \), the second column of \( x \) against the second column of \( y \), etc. If one matrix has fewer columns, plotting will cycle back through the columns again. (In particular, either \( x \) or \( y \) may be a vector, against which all columns of the other argument will be plotted.)

The first element of \( \text{col} \), \( \text{cex} \), \( \text{lty} \), \( \text{lwd} \) is used to plot the axes as well as the first line.

Because plotting symbols are drawn with lines and because these functions may be changing the line style, you should probably specify \( \text{lty} = 1 \) when using plotting symbols.

**Side Effects**

Function \( \text{matplot} \) generates a new plot; \( \text{matpoints} \) and \( \text{matlines} \) add to the current one.

                    sep = "=", collapse = " ",
                    main = "Fisher's Iris Data")
par(op)

mosaicplot Mosaic Plots

Description
Plots a mosaic on the current graphics device.

Usage
mosaicplot(x, ...)
## Default S3 method:
mosaicplot(x, main = deparse(substitute(x)),
            sub = NULL, xlab = NULL, ylab = NULL,
            sort = NULL, off = NULL, dir = NULL,
            color = NULL, shade = FALSE, margin = NULL,
            cex.axis = 0.66, las = par("las"), border = NULL,
            type = c("pearson", "deviance", "FT"), ...)

mosaicplot(formula, data = NULL, ...,
            main = deparse(substitute(data)), subset,
            na.action = stats::na.omit)

Arguments

x a contingency table in array form, with optional category labels specified in the
dimnames(x) attribute. The table is best created by the table() command.

main character string for the mosaic title.

sub character string for the mosaic sub-title (at bottom).

xlab, ylab x- and y-axis labels used for the plot; by default, the first and second element of
names(dimnames(X)) (i.e., the name of the first and second variable in X).

sort vector ordering of the variables, containing a permutation of the integers
1:length(dim(x)) (the default).

off vector of offsets to determine percentage spacing at each level of the mosaic
(appropriate values are between 0 and 20, and the default is 20 times the number
of splits for 2-dimensional tables, and 10 otherwise. Rescaled to maximally 50,
and recycled if necessary.)
mosaicplot

**dir**
vector of split directions ("v" for vertical and "h" for horizontal) for each level of the mosaic, one direction for each dimension of the contingency table. The default consists of alternating directions, beginning with a vertical split.

**color**
logical or (recycling) vector of colors for color shading, used only when shade is FALSE, or NULL (default). By default, grey boxes are drawn. color = TRUE uses a gamma-corrected grey palette. color = FALSE gives empty boxes with no shading.

**shade**
a logical indicating whether to produce extended mosaic plots, or a numeric vector of at most 5 distinct positive numbers giving the absolute values of the cut points for the residuals. By default, shade is FALSE, and simple mosaics are created. Using shade = TRUE cuts absolute values at 2 and 4.

**margin**
a list of vectors with the marginal totals to be fit in the log-linear model. By default, an independence model is fitted. See loglin for further information.

**cex.axis**
The magnification to be used for axis annotation, as a multiple of par("cex").

**las**
numeric; the style of axis labels, see par.

**border**
colour of borders of cells: see polygon.

**type**
a character string indicating the type of residual to be represented. Must be one of "pearson" (giving components of Pearson’s $\chi^2$), "deviance" (giving components of the likelihood ratio $\chi^2$), or "FT" for the Freeman-Tukey residuals. The value of this argument can be abbreviated.

**formula**
a formula, such as $y \sim x$.

**data**
a data frame (or list), or a contingency table from which the variables in formula should be taken.

... further arguments to be passed to or from methods.

**subset**
an optional vector specifying a subset of observations in the data frame to be used for plotting.

**na.action**
a function which indicates what should happen when the data contains variables to be cross-tabulated, and these variables contain NAs. The default is to omit cases which have an NA in any variable. Since the tabulation will omit all cases containing missing values, this will only be useful if the na.action function replaces missing values.

**Details**
This is a generic function. It currently has a default method (mosaicplot.default) and a formula interface (mosaicplot.formula).

Extended mosaic displays visualize standardized residuals of a loglinear model for the table by color and outline of the mosaic’s tiles. (Standardized residuals are often referred to a standard normal distribution.) Cells representing negative residuals are drawn in shaded of red and with broken borders; positive ones are drawn in blue with solid borders.

For the formula method, if data is an object inheriting from class "table" or class "ftable" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be non-negative. In this case the left-hand side of formula should be empty and the variables on the right-hand side should be taken from the names of the dimnames attribute of the contingency table. A marginal table of these variables is computed, and a mosaic plot of that table is produced. Otherwise, data should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, after possibly selecting a subset of the data as specified by the subset
mosaicplot

argument, a contingency table is computed from the variables given in formula, and a mosaic is produced from this.

See Emerson (1998) for more information and a case study with television viewer data from Nielsen Media Research.

Missing values are not supported except via an na.action function when data contains variables to be cross-tabulated.

A more flexible and extensible implementation of mosaic plots written in the grid graphics system is provided in the function mosaic in the contributed package vcd (Meyer, Zeileis and Hornik, 2005).

# color recycling
mosaicplot(~ gear + carb, data = mtcars, color = 2:3, las = 1)

---

### mtext

#### Write Text into the Margins of a Plot

**Description**

Text is written in one of the four margins of the current figure region or one of the outer margins of the device region.

**Usage**

```r
mtext(text, side = 3, line = 0, outer = FALSE, at = NA,
adj = NA, padj = NA, cex = NA, col = NA, font = NA, ...)
```

**Arguments**

- `text`: a character or expression vector specifying the text to be written. Other objects are coerced by `as.graphicsAnnot`.
- `side`: on which side of the plot (1=bottom, 2=left, 3=top, 4=right).
- `line`: on which MARGIN line, starting at 0 counting outwards.
- `outer`: use outer margins if available.
- `at`: give location of each string in user coordinates. If the component of `at` corresponding to a particular text item is not a finite value (the default), the location will be determined by `adj`.
- `adj`: adjustment for each string in reading direction. For strings parallel to the axes, `adj = 0` means left or bottom alignment, and `adj = 1` means right or top alignment.
  - If `adj` is not a finite value (the default), the value of `par("las")` determines the adjustment. For strings plotted parallel to the axis the default is to centre the string.
- `padj`: adjustment for each string perpendicular to the reading direction (which is controlled by `adj`). For strings parallel to the axes, `padj = 0` means right or top alignment, and `padj = 1` means left or bottom alignment.
  - If `padj` is not a finite value (the default), the value of `par("las")` determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.
- `cex`: character expansion factor. NULL and NA are equivalent to 1.0. This is an absolute measure, not scaled by `par("cex")` or by setting `par("mfrow")` or `par("mfcol")`. Can be a vector.
- `col`: color to use. Can be a vector. NA values (the default) mean use `par("col")`.
- `font`: font for text. Can be a vector. NA values (the default) mean use `par("font")`.
- `...`: Further graphical parameters (see `par`), including family, las and xpd. (The latter defaults to the figure region unless `outer = TRUE`, otherwise the device region. It can only be increased.)
pairs

Details

The user coordinates in the outer margins always range from zero to one, and are not affected by the user coordinates in the figure region(s) — R differs here from other implementations of S.

All of the named arguments can be vectors, and recycling will take place to plot as many strings as the longest of the vector arguments.

Note that a vector \( \text{adj} \) has a different meaning from \( \text{text} \). \( \text{adj} = 0.5 \) will centre the string, but for \( \text{outer} = \text{TRUE} \) on the device region rather than the plot region.

Parameter \( \text{las} \) will determine the orientation of the string(s). For strings plotted perpendicular to the axis the default justification is to place the end of the string nearest the axis on the specified line. (Note that this differs from S, which uses \( \text{srt} \) if \( \text{at} \) is supplied and \( \text{las} \) if it is not. Parameter \( \text{srt} \) is ignored in R.)

Note that if the text is to be plotted perpendicular to the axis, \( \text{adj} \) determines the justification of the string and the position along the axis unless \( \text{at} \) is specified.

Graphics parameter "\( \text{ylbias} \)" (see \( \text{par} \)) determines how the text baseline is placed relative to the nominal line.

Side Effects

The given text is written onto the current plot.

Examples

plot(1:10, (-4:5)^2, main = "Parabola Points", xlab = "xlab")
mtext("10 of them")
for(s in 1:4)
  mtext(paste("mtext(..., line= -1, \{side, col, font\} = ", s,
  "\", cex = ", (t+s)/2, "\")\), line = -1,
  side = s, col = s, font = s, cex = (t+s)/2)
mtext("mtext(..., line= -2)\), line = -2)
mtext("mtext(..., line= -2, \text{adj} = 0\), line = -2, adj = 0)
##--- log axis :
plot(1:10, exp(1:10), log = "y", main = "log =\"y\"\", xlab = "xlab")
for(s in 1:4) mtext(paste("mtext(...,side=", s ,"\"), side = s)

pairs

Scatterplot Matrices

Description

A matrix of scatterplots is produced.
Usage

pairs(x, ...)

## S3 method for class 'formula'
pairs(formula, data = NULL, ..., subset,
       na.action = stats::na.pass)

## Default S3 method:
pairs(x, labels, panel = points, ...,
       horInd = 1:nc, verInd = 1:nc,
       lower.panel = panel, upper.panel = panel,
       diag.panel = NULL, text.panel = textPanel,
       label.pos = 0.5 + has.diag/3, line.main = 3,
       cex.labels = NULL, font.labels = 1,
       row1atop = TRUE, gap = 1, log = "")

Arguments

x the coordinates of points given as numeric columns of a matrix or data frame. Logical and factor columns are converted to numeric in the same way that data.matrix does.

formula a formula, such as ~ x + y + z. Each term will give a separate variable in the pairs plot, so terms should be numeric vectors. (A response will be interpreted as another variable, but not treated specially, so it is confusing to use one.)

data a data.frame (or list) from which the variables in formula should be taken.

subset an optional vector specifying a subset of observations to be used for plotting.

na.action a function which indicates what should happen when the data contain NAs. The default is to pass missing values on to the panel functions, but na.action = na.omit will cause cases with missing values in any of the variables to be omitted entirely.

labels the names of the variables.

panel function(x, y, ...) which is used to plot the contents of each panel of the display.

... arguments to be passed to or from methods.

Also, graphical parameters can be given as can arguments to plot such as main. par("oma") will be set appropriately unless specified.

horInd, verInd The (numerical) indices of the variables to be plotted on the horizontal and vertical axes respectively.

lower.panel, upper.panel separate panel functions (or NULL) to be used below and above the diagonal respectively.

diag.panel optional function(x, ...) to be applied on the diagonals.

text.panel optional function(x, y, labels, cex, font, ...) to be applied on the diagonals.

label.pos y position of labels in the text panel.

line.main if main is specified, line.main gives the line argument to mtext() which draws the title. You may want to specify oma when changing line.main.
pairs

cex.labels, font.labels
  graphics parameters for the text panel.
row1atop
  logical. Should the layout be matrix-like with row 1 at the top, or graph-like
  with row 1 at the bottom?
gap
  distance between subplots, in margin lines.
log
  a character string indicating if logarithmic axes are to be used: see
  plot.default. log = "xy" specifies logarithmic axes for all variables.

Details

The $ij$th scatterplot contains $x[,i]$ plotted against $x[,j]$. The scatterplot can be customised by
setting panel functions to appear as something completely different. The off-diagonal panel func-
tions are passed the appropriate columns of $x$ as $x$ and $y$: the diagonal panel function (if any) is
passed a single column, and the text.panel function is passed a single $(x, y)$ location and the
column name. Setting some of these panel functions to NULL is equivalent to not drawing anything
there.

The graphical parameters pch and col can be used to specify a vector of plotting symbols and colors
to be used in the plots.

The graphical parameter oma will be set by pairs.default unless supplied as an argument.
A panel function should not attempt to start a new plot, but just plot within a given coordinate
system: thus plot and boxplot are not panel functions.

By default, missing values are passed to the panel functions and will often be ignored within a panel.
However, for the formula method and na.action = na.omit, all cases which contain a missing
values for any of the variables are omitted completely (including when the scales are selected).
Arguments horInd and verInd were introduced in R 3.2.0. If given the same value they can be
used to select or re-order variables: with different ranges of consecutive values they can be used to
plot rectangular windows of a full pairs plot; in the latter case ‘diagonal’ refers to the diagonal of
the full plot.

      subset = Education < 20, main = "Swiss data, Education < 20")

pairs(USJudgeRatings)

## show only lower triangle (and suppress labeling for whatever reason):
pairs(USJudgeRatings, text.panel = NULL, upper.panel = NULL)

## put histograms on the diagonal
panel.smooth

Simple Panel Plot

Description

An example of a simple useful panel function to be used as argument in e.g., coplot or pairs.

Usage

panel.smooth(x, y, col = par("col"), bg = NA, pch = par("pch"),
  cex = 1, col.smooth = "red", span = 2/3, iter = 3,
  ...)

Arguments

x, y numeric vectors of the same length
col, bg, pch, cex numeric or character codes for the color(s), point type and size of points; see also par.

span smoothing parameter f for lowess, see there.

iter number of robustness iterations for lowess.

... further arguments to lines.

panel.hist <- function(x, ...
{
  usr <- par("usr"); on.exit(par(usr))
  par(usr = c(usr[1:2], 0, 1.5))
  h <- hist(x, plot = FALSE)
  breaks <- h$breaks; nB <- length(breaks)
  y <- h$counts; y <- y/max(y)
  rect(breaks[-nB], 0, breaks[-1], y, col = "cyan", ...)
}

pairs(USJudgeRatings[1:5], panel = panel.smooth,
  cex = 1.5, pch = 24, bg = "light blue",
  diag.panel = panel.hist, cex.labels = 2, font.labels = 2)

## put (absolute) correlations on the upper panels,
## with size proportional to the correlations.
panel.cor <- function(x, y, digits = 2, prefix = ",
{
  usr <- par("usr"); on.exit(par(usr))
  par(usr = c(0, 1, 0, 1))
  r <- abs(cor(x, y))
  txt <- format(c(r, 0.123456789), digits = digits)[1]
  txt <- paste0(prefix, txt)
  if(missing(cex.cor)) cex.cor <- 0.8/strwidth(txt)
  text(0.5, 0.5, txt, cex = cex.cor * r)
}
pairs(USJudgeRatings, lower.panel = panel.smooth, upper.panel = panel.cor)
pairs(iris[-5], log = "xy") # plot all variables on log scale

par

Set or Query Graphical Parameters

Description
par can be used to set or query graphical parameters. Parameters can be set by specifying them as arguments to par in tag = value form, or by passing them as a list of tagged values.

Usage

par(..., no.readonly = FALSE)

<highlevel plot> (...<tag> = <value>)

Arguments

... arguments in tag = value form, or a list of tagged values. The tags must come from the names of graphical parameters described in the ‘Graphical Parameters’ section.

no.readonly logical; if TRUE and there are no other arguments, only parameters are returned which can be set by a subsequent par() call on the same device.

Details

Each device has its own set of graphical parameters. If the current device is the null device, par will open a new device before querying/setting parameters. (What device is controlled by options("device").)

Parameters are queried by giving one or more character vectors of parameter names to par.

par() (no arguments) or par(no.readonly = TRUE) is used to get all the graphical parameters (as a named list). Their names are currently taken from the unexported variable graphics:::.Pars.

R.O. indicates read-only arguments: These may only be used in queries and cannot be set. ("cin", "cra", "csi", "cxy", "din" and "page" are always read-only.)

Several parameters can only be set by a call to par():

- "ask",
- "fig", "fin",
- "lheight",
- "mai", "mar", "mex", "mfcol", "mfrow", "mfg",
- "new",
- "oma", "omd", "omi"
• "pin", "plt", "ps", "pty",
• "usr",
• "xlog", "ylog",
• "ylbias"

The remaining parameters can also be set as arguments (often via ... ) to high-level plot functions such as plot.default, plot.window, points, lines, abline, axis, title, text, mtext, segments, symbols, arrows, polygon, rect, box, contour, filled.contour and image. Such settings will be active during the execution of the function, only. However, see the comments on bg, cex, col, lty, lwd and pch which may be taken as arguments to certain plot functions rather than as graphical parameters.

The meaning of 'character size' is not well-defined: this is set up for the device taking pointsize into account but often not the actual font family in use. Internally the corresponding pars (cra, cin, cxy and csi) are used only to set the inter-line spacing used to convert mar and oma to physical margins. (The same inter-line spacing multiplied by 1height is used for multi-line strings in text and strheight.)

Note that graphical parameters are suggestions: plotting functions and devices need not make use of them (and this is particularly true of non-default methods for e.g. plot).

Value

When parameters are set, their previous values are returned in an invisible named list. Such a list can be passed as an argument to par to restore the parameter values. Use par(no.readonly = TRUE) for the full list of parameters that can be restored. However, restoring all of these is not wise: see the ‘Note’ section.

When just one parameter is queried, the value of that parameter is returned as (atomic) vector. When two or more parameters are queried, their values are returned in a list, with the list names giving the parameters.

Note the inconsistency: setting one parameter returns a list, but querying one parameter returns a vector.

Graphical Parameters

adj The value of adj determines the way in which text strings are justified in text, mtext and title. A value of 0 produces left-justified text, 0.5 (the default) centered text and 1 right-justified text. (Any value in \([0, 1]\) is allowed, and on most devices values outside that interval will also work.)

Note that the adj argument of text also allows adj = c(x, y) for different adjustment in x- and y- directions. Note that whereas for text it refers to positioning of text about a point, for mtext and title it controls placement within the plot or device region.

ann If set to FALSE, high-level plotting functions calling plot.default do not annotate the plots they produce with axis titles and overall titles. The default is to do annotation.

ask logical. If TRUE (and the R session is interactive) the user is asked for input, before a new figure is drawn. As this applies to the device, it also affects output by packages grid and lattice. It can be set even on non-screen devices but may have no effect there.

This not really a graphics parameter, and its use is deprecated in favour of devAskNewPage.

bg The color to be used for the background of the device region. When called from par() it also sets new = FALSE. See section ‘Color Specification’ for suitable values. For many devices the initial value is set from the bg argument of the device, and for the rest it is normally "white".

Note that some graphics functions such as plot.default and points have an argument of this name with a different meaning.
A character string which determines the type of box which is drawn about plots. If bty is one of "o" (the default), "l", "7", "c", "u", or "\"" the resulting box resembles the corresponding upper case letter. A value of "n" suppresses the box.

cex A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default. This starts as 1 when a device is opened, and is reset when the layout is changed, e.g. by setting mrow.

Note that some graphics functions such as plot.default have an argument of this name which multiplies this graphical parameter, and some functions such as points and text accept a vector of values which are recycled.

cex.axis The magnification to be used for axis annotation relative to the current setting of cex.

cex.lab The magnification to be used for x and y labels relative to the current setting of cex.

cex.main The magnification to be used for main titles relative to the current setting of cex.

cex.sub The magnification to be used for sub-titles relative to the current setting of cex.

cin R.O.; character size (width, height) in inches. These are the same measurements as cra, expressed in different units.

col A specification for the default plotting color. See section 'Color Specification'.

Some functions such as lines and text accept a vector of values which are recycled and may be interpreted slightly differently.

col.axis The color to be used for axis annotation. Defaults to "black".

col.lab The color to be used for x and y labels. Defaults to "black".

col.main The color to be used for plot main titles. Defaults to "black".

col.sub The color to be used for plot sub-titles. Defaults to "black".

cra R.O.; size of default character (width, height) in 'rasters' (pixels). Some devices have no concept of pixels and so assume an arbitrary pixel size, usually 1/72 inch. These are the same measurements as cin, expressed in different units.

crt A numerical value specifying (in degrees) how single characters should be rotated. It is unwise to expect values other than multiples of 90 to work. Compare with srt which does string rotation.

csi R.O.; height of (default-sized) characters in inches. The same as par("cin")[2].

cxy R.O.; size of default character (width, height) in user coordinate units. par("cxy") is par("cin")/par("pin") scaled to user coordinates. Note that c(strwidth(ch), strheight(ch)) for a given string ch is usually much more precise.

din R.O.; the device dimensions, (width, height), in inches. See also dev.size, which is updated immediately when an on-screen device windows is re-sized.

err (Unimplemented; \ R \ is silent when points outside the plot region are not plotted.) The degree of error reporting desired.

family The name of a font family for drawing text. The maximum allowed length is 200 bytes. This name gets mapped by each graphics device to a device-specific font description. The default value is "" which means that the default device fonts will be used (and what those are should be listed on the help page for the device). Standard values are "serif", "sans" and "mono", and the Hershey font families are also available. (Devices may define others, and some devices will ignore this setting completely. Names starting with "Hershey" are treated specially and should only be used for the built-in Hershey font families.) This can be specified inline for text.
fg The color to be used for the foreground of plots. This is the default color used for things like axes and boxes around plots. When called from `par()` this also sets parameter `col` to the same value. See section ‘Color Specification’. A few devices have an argument to set the initial value, which is otherwise “black”.

fig A numerical vector of the form \( c(x_1, x_2, y_1, y_2) \) which gives the (NDC) coordinates of the figure region in the display region of the device. If you set this, unlike S, you start a new plot, so to add to an existing plot use `new = TRUE` as well.

fin The figure region dimensions, \((\text{width, height})\), in inches. If you set this, unlike S, you start a new plot.

font An integer which specifies which font to use for text. If possible, device drivers arrange so that 1 corresponds to plain text (the default), 2 to bold face, 3 to italic and 4 to bold italic. Also, font 5 is expected to be the symbol font, in Adobe symbol encoding. On some devices font families can be selected by `family` to choose different sets of 5 fonts.

font.axis The font to be used for axis annotation.

font.lab The font to be used for x and y labels.

font.main The font to be used for plot main titles.

font.sub The font to be used for plot sub-titles.

lab A numerical vector of the form \( c(x, y, 1\text{en}) \) which modifies the default way that axes are annotated. The values of \( x \) and \( y \) give the (approximate) number of tickmarks on the x and y axes and \( 1\text{en} \) specifies the label length. The default is \( c(5, 5, 7) \). Note that this only affects the way the parameters `xaxp` and `yaxp` are set when the user coordinate system is set up, and is not consulted when axes are drawn. \( 1\text{en} \) is unimplemented in \( \text{R} \).

las numeric in \{0,1,2,3\}; the style of axis labels.

0: always parallel to the axis [default].
1: always horizontal,
2: always perpendicular to the axis,
3: always vertical.

Also supported by `mtext`. Note that string/character rotation via argument `srt` to `par` does not affect the axis labels.

lend The line end style. This can be specified as an integer or string:

0 and “round” mean rounded line caps [default];
1 and “butt” mean butt line caps;
2 and “square” mean square line caps.

lheight The line height multiplier. The height of a line of text (used to vertically space multi-line text) is found by multiplying the character height both by the current character expansion and by the line height multiplier. Default value is 1. Used in `text` and `strheight`.

ljoin The line join style. This can be specified as an integer or string:

0 and “round” mean rounded line joins [default];
1 and “mitre” mean mitred line joins;
2 and “bevel” mean bevelled line joins.

lmitre The line mitre limit. This controls when mitred line joins are automatically converted into bevelled line joins. The value must be larger than 1 and the default is 10. Not all devices will honour this setting.

lty The line type. Line types can either be specified as an integer \(0=\text{blank}, 1=\text{solid} \) (default), \(2=\text{dashed}, 3=\text{dotted}, 4=\text{dotdash}, 5=\text{longdash}, 6=\text{twodash} \) or as one of the character strings
"blank", "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash", where
"blank" uses ‘invisible lines’ (i.e., does not draw them).
Alternatively, a string of up to 8 characters (from c(1:9,   "A":"F") may be given,
giving the length of line segments which are alternatively drawn and skipped. See section
‘Line Type Specification’.
Functions such as lines and segments accept a vector of values which are recycled.

lwd The line width, a positive number, defaulting to 1. The interpretation is device-specific, and
some devices do not implement line widths less than one. (See the help on the device for
details of the interpretation.)
Functions such as lines and segments accept a vector of values which are recycled: in such
uses lines corresponding to values NA or NaN are omitted. The interpretation of 0 is device-
specific.

mai A numerical vector of the form c(bottom, left, top, right) which gives the
margin size specified in inches.

mar A numerical vector of the form c(bottom, left, top, right) which gives the
number of lines of margin to be specified on the four sides of the plot. The default is
c(5, 4, 4, 2) + 0.1.

mex mex is a character size expansion factor which is used to describe coordinates in the margins
of plots. Note that this does not change the font size, rather specifies the size of font (as a
multiple of csi) used to convert between mar and mai, and between oma and omi.
This starts as 1 when the device is opened, and is reset when the layout is changed (alongside
resetting cex).
mfcol, mfrow A vector of the form c(nr, nc). Subsequent figures will be drawn in an nr-by-nc
array on the device by columns (mfcol), or rows (mfrow), respectively.
In a layout with exactly two rows and columns the base value of "cex" is reduced by a factor
of 0.83: if there are three or more of either rows or columns, the reduction factor is 0.66.
Setting a layout resets the base value of cex and that of mex to 1.
If either of these is queried it will give the current layout, so querying cannot tell you the order
in which the array will be filled.
Consider the alternatives, layout and split.screen.
mfg A numerical vector of the form c(i, j) where i and j indicate which figure in an array of
figures is to be drawn next (if setting) or is being drawn (if enquiring). The array must already
have been set by mfcol or mfrow.
For compatibility with S, the form \( c(i, j, nr, nc) \) is also accepted, when \( nr \) and \( nc \) should be the current number of rows and number of columns. Mismatches will be ignored, with a warning.

**mgp**
The margin line (in \( \text{mex} \) units) for the axis title, axis labels and axis line. Note that \( \text{mgp}[1] \) affects \textit{title} whereas \( \text{mgp}[2:3] \) affect \textit{axis}. The default is \( c(3, 1, 0) \).

**mih**
The height in inches of symbols to be drawn when the value of \( pch \) is an integer. \textit{Completely ignored in R}.

**new**
Logical, defaulting to FALSE. If set to TRUE, the next high-level plotting command (actually \texttt{plot.new}) should not clean the frame before drawing \textit{as if it were on a new device}. It is an error (ignored with a warning) to try to use \( \text{new} = \text{TRUE} \) on a device that does not currently contain a high-level plot.

**oma**
A vector of the form \( c(\text{bottom, left, top, right}) \) giving the size of the outer margins in lines of text.

**omd**
A vector of the form \( c(x1, x2, y1, y2) \) giving the region inside outer margins in NDC (= normalized device coordinates), i.e., as a fraction (in \([0, 1]\)) of the device region.

**omi**
A vector of the form \( c(\text{bottom, left, top, right}) \) giving the size of the outer margins in inches.

**page**
\texttt{R.O.}: A boolean value indicating whether the next call to \texttt{plot.new} is going to start a new page. This value may be FALSE if there are multiple figures on the page.

**pch**
Either an integer specifying a symbol or a single character to be used as the default in plotting points. See \texttt{points} for possible values and their interpretation. Note that only integers and single-character strings can be set as a graphics parameter (and not NA nor NULL). Some functions such as \texttt{points} accept a vector of values which are recycled.

**pin**
The current plot dimensions, \( (\text{width, height}) \), in inches.

**plt**
A vector of the form \( c(x1, x2, y1, y2) \) giving the coordinates of the plot region as fractions of the current figure region.

**ps**
Integer; the point size of text (but not symbols). Unlike the \texttt{pointsize} argument of most devices, this does not change the relationship between \texttt{mar} and \texttt{mai} (nor \texttt{oma} and \texttt{omi}).

What is meant by ‘point size’ is device-specific, but most devices mean a multiple of 1bp, that is 1/72 of an inch.
par

pty A character specifying the type of plot region to be used; "s" generates a square plotting region and "m" generates the maximal plotting region.

smo (Unimplemented) a value which indicates how smooth circles and circular arcs should be.

srt The string rotation in degrees. See the comment about crt. Only supported by text.

tck The length of tick marks as a fraction of the smaller of the width or height of the plotting region. If tck \geq 0.5 it is interpreted as a fraction of the relevant side, so if tck = 1 grid lines are drawn. The default setting (tck = NA) is to use tcl = -0.5.

usr A vector of the form c(x1, x2, y1, y2) giving the extremes of the user coordinates of the plotting region. When a logarithmic scale is in use (i.e., par("xlog") is true, see below), then the x-limits will be $10^{\text{par("usr")}[1:2]}$. Similarly for the y-axis.

xaxp A vector of the form c(x1, x2, n) giving the coordinates of the extreme tick marks and the number of intervals between tick-marks unless for log coordinates, see xaxp above. n = 1 will produce tick marks at $10^j$ for integer j, n = 2 gives marks $k10^j$ with $k \in \{1, 5\}$, n = 3 gives marks $k10^j$ with $k \in \{1, 2, 5\}$. See axTicks() for a pure R implementation of this.

This parameter is reset when a user coordinate system is set up, for example by starting a new page or by calling plot.window or setting par("usr"): n is taken from par("lab"). It affects the default behaviour of subsequent calls to axis for sides 1 or 3. It is only relevant to default numeric axis systems, and not for example to dates.

xaxs The style of axis interval calculation to be used for the x-axis. Possible values are "r", "i", "e", "s", "d". The styles are generally controlled by the range of data or xlim, if given. Style "r" (regular) first extends the data range by 4 percent at each end and then finds an axis with pretty labels that fits within the extended range. Style "i" (internal) just finds an axis with pretty labels that fits within the original data range. Style "s" (standard) finds an axis with pretty labels within which the original data range fits. Style "e" (extended) is like style "s", except that it is also ensures that there is room for plotting symbols within the bounding box. Style "d" (direct) specifies that the current axis should be used on subsequent plots. (Only "r" and "i" styles have been implemented in R.)

xaxt A character which specifies the x axis type. Specifying "n" suppresses plotting of the axis. The standard value is "s": for compatibility with S values "1" and "t" are accepted but are equivalent to "s": any value other than "n" implies plotting.

xlog A logical value (see log in plot.default). If TRUE, a logarithmic scale is in use (e.g., after plot(*, log = "x")). For a new device, it defaults to FALSE, i.e., linear scale.

xpd A logical value or NA. If FALSE, all plotting is clipped to the plot region, if TRUE, all plotting is clipped to the figure region, and if NA, all plotting is clipped to the device region. See also clip.

yaxp A vector of the form c(y1, y2, n) giving the coordinates of the extreme tick marks and the number of intervals between tick-marks unless for log coordinates, see xaxp above.

yaxs The style of axis interval calculation to be used for the y-axis. See xaxs above.
par

yaxt  A character which specifies the y axis type. Specifying "n" suppresses plotting.

ylbias  A positive real value used in the positioning of text in the margins by axis and mtext. The default is in principle device-specific, but currently 0.2 for all of R’s own devices. Set this to 0.2 for compatibility with R < 2.14.0 on x11 and windows() devices.

ylog  A logical value; see xlog above.

**Color Specification**

Colors can be specified in several different ways. The simplest way is with a character string giving the color name (e.g., "red"). A list of the possible colors can be obtained with the function colors. Alternatively, colors can be specified directly in terms of their RGB components with a string of the form "#RRGGBB" where each of the pairs RR, GG, BB consist of two hexadecimal digits giving a value in the range 00 to FF. Colors can also be specified by giving an index into a small table of colors, the palette: indices wrap round so with the default palette of size 8, 10 is the same as 2. This provides compatibility with S. Index 0 corresponds to the background color. Note that the palette (apart from 0 which is per-device) is a per-session setting. Negative integer colours are errors.

Additionally, "transparent" is transparent, useful for filled areas (such as the background!), and just invisible for things like lines or text. In most circumstances (integer) NA is equivalent to "transparent" (but not for text and mtext).

Semi-transparent colors are available for use on devices that support them.

The functions rgb, hsv, hcl, gray and rainbow provide additional ways of generating colors.

**Line Type Specification**

Line types can either be specified by giving an index into a small built-in table of line types (1 = solid, 2 = dashed, etc, see lty above) or directly as the lengths of on/off stretches of line. This is done with a string of an even number (up to eight) of characters, namely non-zero (hexadecimal) digits which give the lengths in consecutive positions in the string. For example, the string "33" specifies three units on followed by three off and "3313" specifies three units on followed by one on and finally three off. The ‘units’ here are (on most devices) proportional to lwd, and with lwd = 1 are in pixels or points or 1/96 inch.

The five standard dash-dot line types (lty = 2:6) correspond to c("44", "13", "1343", "73", "2262").

Note that NA is not a valid value for lty.

**Note**

The effect of restoring all the (settable) graphics parameters as in the examples is hard to predict if the device has been resized. Several of them are attempting to set the same things in different ways, and those last in the alphabet will win. In particular, the settings of mai, mar, pin, plt and pty interact, as do the outer margin settings, the figure layout and figure region size.

Examples

```r
op <- par(mfrow = c(2, 2), # 2 x 2 pictures on one plot
    pty = "s") # square plotting region,
    # independent of device size

## At end of plotting, reset to previous settings:
par(op)

## Alternatively,
op <- par(no.readonly = TRUE) # the whole list of settable par's.
## do lots of plotting and par(.) calls, then reset:
par(op)
## Note this is not in general good practice

par("ylog") # FALSE
plot(1 : 12, log = "y")
par("ylog") # TRUE

plot(1:2, xaxs = "i") # 'inner axis' w/o extra space
par(c("usr", "xaxp"))

(nr.prof <-
c(prof.pilots = 16, lawyers = 11, farmers = 10, salesmen = 9, physicians = 9,
    mechanics = 6, policemen = 6, managers = 6, engineers = 5, teachers = 4,
    housewives = 3, students = 3, armed.forces = 1))
par(las = 3)
barplot(rbind(nr.prof)) # R 0.63.2: shows alignment problem
par(las = 0) # reset to default

require(grDevices) # for gray
## 'fg' use:
plot(1:12, type = "b", main = "fg : axes, ticks and box in gray",
    fg = gray(0.7), bty = "7", sub = R.version.string)

ex <- function() {
    old.par <- par(no.readonly = TRUE) # all par settings which
        # could be changed.
on.exit(par(old.par))
    ## ...
    ## ... do lots of par() settings and plots
    ## ...
invisible() #-- now, par(old.par) will be executed
}
ex()

## Line types
showLty <- function(ltys, xoff = 0, ...) {
    stopifnot((n <- length(ltys)) > 0)
    op <- par(mar = rep(.5,4)); on.exit(par(op))
    plot(0:1, 0:1, type = "n", axes = FALSE, ann = FALSE)
    ```
persp

Perspective Plots

Description

This function draws perspective plots of a surface over the x–y plane. persp is a generic function.

Usage

persp(x, ...)

## Default S3 method:
persp(x = seq(0, 1, length.out = nrow(z)),
y = seq(0, 1, length.out = ncol(z)),
z, xlim = range(x), ylim = range(y),
zlim = range(z, na.rm = TRUE),
xlab = NULL, ylab = NULL, zlab = NULL,
main = NULL, sub = NULL,
theta = 0, phi = 15, r = sqrt(3), d = 1,
scale = TRUE, expand = 1,
col = "white", border = NULL, ltheta = -135, lphi = 0,
shade = NA, box = TRUE, axes = TRUE, nticks = 5,
ticktype = "simple", ...)

Arguments

x, y

locations of grid lines at which the values in z are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x$x and x$y are used for x and y, respectively.

z

a matrix containing the values to be plotted (NAs are allowed). Note that x can be used instead of z for convenience.

xlim, ylim, zlim

x-, y- and z-limits. These should be chosen to cover the range of values of the surface: see ‘Details’.

xlab, ylab, zlab

titles for the axes. N.B. These must be character strings; expressions are not accepted. Numbers will be coerced to character strings.

main, sub

main and sub title, as for title.
persp

theta, phi angles defining the viewing direction. theta gives the azimuthal direction and phi the colatitude.

r the distance of the eyepoint from the centre of the plotting box.

d a value which can be used to vary the strength of the perspective transformation. Values of d greater than 1 will lessen the perspective effect and values less and 1 will exaggerate it.

scale before viewing the x, y and z coordinates of the points defining the surface are transformed to the interval [0,1]. If scale is TRUE the x, y and z coordinates are transformed separately. If scale is FALSE the coordinates are scaled so that aspect ratios are retained. This is useful for rendering things like DEM information.

expand a expansion factor applied to the z coordinates. Often used with 0 < expand < 1 to shrink the plotting box in the z direction.

col the color(s) of the surface facets. Transparent colours are ignored. This is recycled to the \((nx-1)(ny-1)\) facets.

border the color of the line drawn around the surface facets. The default, NULL, corresponds to par("fg"). A value of NA will disable the drawing of borders: this is sometimes useful when the surface is shaded.

ltheta, lphi if finite values are specified for ltheta and lphi, the surface is shaded as though it was being illuminated from the direction specified by azimuth ltheta and colatitude lphi.

shade the shade at a surface facet is computed as \(((1+d)/2)^\text{shade}\), where d is the dot product of a unit vector normal to the facet and a unit vector in the direction of a light source. Values of shade close to one yield shading similar to a point light source model and values close to zero produce no shading. Values in the range 0.5 to 0.75 provide an approximation to daylight illumination.

box should the bounding box for the surface be displayed. The default is TRUE.

axes should ticks and labels be added to the box. The default is TRUE. If box is FALSE then no ticks or labels are drawn.

ticktype character: "simple" draws just an arrow parallel to the axis to indicate direction of increase; "detailed" draws normal ticks as per 2D plots.

nticks the (approximate) number of tick marks to draw on the axes. Has no effect if ticktype is "simple".

... additional graphical parameters (see par).

Details

The plots are produced by first transforming the \((x,y,z)\) coordinates to the interval [0,1] using the limits supplied or computed from the range of the data. The surface is then viewed by looking at the origin from a direction defined by theta and phi. If theta and phi are both zero the viewing direction is directly down the negative y axis. Changing theta will vary the azimuth and changing phi the colatitude.

There is a hook called "persp" (see setHook) called after the plot is completed, which is used in the testing code to annotate the plot page. The hook function(s) are called with no argument.

Notice that persp interprets the z matrix as a table of \(f(x[i], y[j])\) values, so that the x axis corresponds to row number and the y axis to column number, with column 1 at the bottom, so that with the standard rotation angles, the top left corner of the matrix is displayed at the left hand side, closest to the user.
The sizes and fonts of the axis labels and the annotations for `ticktype = "detailed"` are controlled by graphics parameters "cex.lab"/"font.lab" and "cex.axis"/"font.axis" respectively.

The bounding box is drawn with edges of faces facing away from the viewer (and hence at the back of the box) with solid lines and other edges dashed and on top of the surface. This (and the plotting of the axes) assumes that the axis limits are chosen so that the surface is within the box, and the function will warn if this is not the case.

Value

`persp()` returns the viewing transformation matrix, say VT, a $4 \times 4$ matrix suitable for projecting 3D coordinates $(x, y, z)$ into the 2D plane using homogeneous 4D coordinates $(x, y, z, t)$. It can be used to superimpose additional graphical elements on the 3D plot, by `lines()` or `points()`, using the function `trans3d()`.

References

See Also

`contour` and `image`; `trans3d`.

Rotatable 3D plots can be produced by package *rgl*: other ways to produce static perspective plots are available in packages `lattice` and `scatterplot3d`.

Examples

```r
require(grDevices) # for trans3d
## More examples in demo(persp) !!

par(op)

---

pie

Pie Charts

Description

Draw a pie chart.

Usage

```
pie(x, labels = names(x), edges = 200, radius = 0.8,
clockwise = FALSE, init.angle = if(clockwise) 90 else 0,
density = NULL, angle = 45, col = NULL, border = NULL,
lty = NULL, main = NULL, ...)```

Arguments

- `x`: a vector of non-negative numerical quantities. The values in `x` are displayed as the areas of pie slices.
labels

one or more expressions or character strings giving names for the slices. Other objects are coerced by \texttt{as.graphicsAnnot}. For empty or \texttt{NA} (after coercion to character) labels, no label nor pointing line is drawn.

edges

the circular outline of the pie is approximated by a polygon with this many edges.

radius

the pie is drawn centered in a square box whose sides range from $-1$ to $1$. If the character strings labeling the slices are long it may be necessary to use a smaller radius.

clockwise

logical indicating if slices are drawn clockwise or counter clockwise (i.e., mathematically positive direction), the latter is default.

init.angle

number specifying the \textit{starting angle} (in degrees) for the slices. Defaults to 0 (i.e., ‘3 o’clock’) unless clockwise is true where \texttt{init.angle} defaults to 90 (degrees), (i.e., ‘12 o’clock’).

density

the density of shading lines, in lines per inch. The default value of \texttt{NULL} means that no shading lines are drawn. Non-positive values of \texttt{density} also inhibit the drawing of shading lines.

angle

the slope of shading lines, given as an angle in degrees (counter-clockwise).

col

a vector of colors to be used in filling or shading the slices. If missing a set of 6 pastel colours is used, unless density is specified when \texttt{par(“fg“)} is used.

border, lty

(possibly vectors) arguments passed to \texttt{polygon} which draws each slice.

main

an overall title for the plot.

... \texttt{graphical parameters} can be given as arguments to \texttt{pie}. They will affect the main title and labels only.

Note

Pie charts are a very bad way of displaying information. The eye is good at judging linear measures and bad at judging relative areas. A bar chart or dot chart is a preferable way of displaying this type of data.

Cleveland (1985), page 264: “Data that can be shown by pie charts always can be shown by a dot chart. This means that judgements of position along a common scale can be made instead of the less accurate angle judgements.” This statement is based on the empirical investigations of Cleveland and McGill as well as investigations by perceptual psychologists.

\texttt{dotchart}.

Examples

\begin{verbatim}
require(grDevices)
pie(rep(1, 24), col = rainbow(24), radius = 0.9)
pie.sales <- c(0.12, 0.3, 0.26, 0.16, 0.04, 0.12)
\end{verbatim}
names(pie.sales) <- c("Blueberry", "Cherry", "Apple", "Boston Cream", "Other", "Vanilla Cream")
pie(pie.sales) # default colours
pie(pie.sales, col = c("purple", "violetred1", "green3", "cornsilk", "cyan", "white"))
pie(pie.sales, col = gray(seq(0.4, 1.0, length = 6)))
pie(pie.sales, density = 10, angle = 15 + 10 * 1:6)
pie(pie.sales, clockwise = TRUE, main = "pie(*, clockwise = TRUE)")
segments(0, 0, 0, 1, col = "red", lwd = 2)
text(0, 1, "init.angle = 90", col = "red")
n <- 200
pie(rep(1, n), labels = "", col = rainbow(n), border = NA, main = "pie(*, labels="", col=rainbow(n), border=NA,..")

## Another case showing pie() is rather fun than science:
## (original by FinalBackwardsGlance on http://imgur.com/gallery/wWrpU4X)
pie(c(Sky = 78, "Sunny side of pyramid" = 17, "Shady side of pyramid" = 5), init.angle = 315, col = c("deepskyblue", "yellow", "yellow3"), border = FALSE)

plot

---

### Generic X-Y Plotting

**Description**

Generic function for plotting of R objects. For more details about the graphical parameter arguments, see `par`.

For simple scatter plots, `plot.default` will be used. However, there are plot methods for many R objects, including functions, data.frames, density objects, etc. Use `methods(plot)` and the documentation for these.

**Usage**

`plot(x, y, ...)`

**Arguments**

- `x` the coordinates of points in the plot. Alternatively, a single plotting structure, function or any R object with a plot method can be provided.
- `y` the y coordinates of points in the plot, optional if `x` is an appropriate structure.
- `...` Arguments to be passed to methods, such as graphical parameters (see `par`). Many methods will accept the following arguments:

  - `type` what type of plot should be drawn. Possible types are:
    - "p" for points,
    - "l" for lines,
    - "b" for both,
    - "c" for the lines part alone of "b",
    - "o" for both 'overplotted'.
    - "h" for histogram’ like (or ‘high-density’) vertical lines,
    - "s" for stair steps,
"S" for other steps, see 'Details' below,
• "n" for no plotting.
All other types give a warning or an error; using, e.g., type = "punkte" being equivalent to type = "p" for S compatibility. Note that some methods, e.g. plot.factor, do not accept this.

main an overall title for the plot: see title.
sub a sub title for the plot: see title.
xlab a title for the x axis: see title.
 ylab a title for the y axis: see title.
asp the y/x aspect ratio, see plot.window.

Details

The two step types differ in their x-y preference: Going from \((x_1, y_1)\) to \((x_2, y_2)\) with \(x_1 < x_2\), type = "s" moves first horizontal, then vertical, whereas type = "S" moves the other way around.

See Also

plot.default, plot.formula and other methods; points, lines, par. For thousands of points, consider using smoothScatter() instead of plot().

For X-Y-Z plotting see contour, persp and image.

Examples

```r
require(stats) # for lowess, rpois, rnorm
plot(cars)
lines(lowess(cars))

plot(sin, -pi, 2*pi) # see ?plot.function

## Discrete Distribution Plot:
plot(table(rpois(100, 5)), type = "h", col = "red", lwd = 10,
     main = "rpois(100, lambda = 5)")

## Simple quantiles/ECDF, see ecdf() {library(stats)} for a better one:
plot(x <- sort(rnorm(47)), type = "s", main = "plot(x, type = \"s\")")
points(x, cex = .5, col = "dark red")
```

---

**plot.data.frame**  
**Plot Method for Data Frames**

**Description**

plot.data.frame, a method for the plot generic. It is designed for a quick look at numeric data frames.

**Usage**

```r
## S3 method for class 'data.frame'
plot(x, ...)
```
Arguments

- **x**: object of class `data.frame`.
- **...**: further arguments to `stripchart`, `plot.default` or `pairs`.

Details

This is intended for data frames with numeric columns. For more than two columns it first calls `data.matrix` to convert the data frame to a numeric matrix and then calls `pairs` to produce a scatterplot matrix. This can fail and may well be inappropriate: for example numerical conversion of dates will lose their special meaning and a warning will be given.

For a two-column data frame it plots the second column against the first by the most appropriate method for the first column.

For a single numeric column it uses `stripchart`, and for other single-column data frames tries to find a plot method for the single column.

See Also

data.frame

Examples

```r
plot(OrchardSprays[,1], method = "jitter")
plot(OrchardSprays[4:1])
plot(OrchardSprays)
plot(iris)
plot(iris[5:4])
plot(women)
```

The Default Scatterplot Function

Description

Draw a scatter plot with decorations such as axes and titles in the active graphics window.

Usage

```r
## Default S3 method:
plot(x, y = NULL, type = "p", xlim = NULL, ylim = NULL,
     log = "", main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
     ann = par("ann"), axes = TRUE, frame.plot = axes,
     panel.first = NULL, panel.last = NULL, asp = NA, ...)
```

Arguments

- **x, y**: the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details. If supplied separately, they must be of the same length.
type 1-character string giving the type of plot desired. The following values are possible, for details, see `plot`: "p" for points, "l" for lines, "b" for both points and lines, "c" for empty points joined by lines, "o" for overplotted points and lines, "s" and "S" for stair steps and "h" for histogram-like vertical lines. Finally, "n" does not produce any points or lines.

xlim the x limits (x1, x2) of the plot. Note that x1 $>$ x2 is allowed and leads to a ‘reversed axis’. The default value, NULL, indicates that the range of the finite values to be plotted should be used.

ylim the y limits of the plot.

log a character string which contains "x" if the x axis is to be logarithmic, "y" if the y axis is to be logarithmic and "xy" or "yx" if both axes are to be logarithmic.

main a main title for the plot, see also `title`.

sub a sub title for the plot.

xlab a label for the x axis, defaults to a description of x.

ylab a label for the y axis, defaults to a description of y.

ann a logical value indicating whether the default annotation (title and x and y axis labels) should appear on the plot.

axes a logical value indicating whether both axes should be drawn on the plot. Use `graphical parameter` "xaxt" or "yaxt" to suppress just one of the axes.

frame.plot a logical indicating whether a box should be drawn around the plot.

panel.first an ‘expression’ to be evaluated after the plot axes are set up but before any plotting takes place. This can be useful for drawing background grids or scatterplot smooths. Note that this works by lazy evaluation: passing this argument from other `plot` methods may well not work since it may be evaluated too early.

panel.last an expression to be evaluated after plotting has taken place but before the axes, title and box are added. See the comments about `panel.first`.

asp the y/x aspect ratio, see `plot.window`.

... other graphical parameters (see `par` and section ‘Details’ below).

Details

Commonly used graphical parameters are:

col The colors for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified.

bg a vector of background colors for open plot symbols, see `points`. Note: this is not the same setting as `par("bg")`.

pch a vector of plotting characters or symbols: see `points`.

cex a numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of `par("cex")`. NULL and NA are equivalent to 1.0. Note that this does not affect annotation: see below.

lty a vector of line types, see `par`.

cex.main, col.lab, font.sub, etc settings for main- and sub-title and axis annotation, see `title` and `par`.

lwd a vector of line widths, see `par`. 
Note

The presence of panel.first and panel.last is a historical anomaly: default plots do not have 'panels', unlike e.g. pairs plots. For more control, use lower-level plotting functions: plot.default calls in turn some of plot.new, plot.window, plot.xy, axis, box and title, and plots can be built up by calling these individually, or by calling plot(type = "n") and adding further elements.

plot, plot.window, xy.coords. For thousands of points, consider using smoothScatter instead.

Examples

Speed <- cars$speed
Distance <- cars$dist
plot(Speed, Distance, panel.first = grid(8, 8),
     pch = 0, cex = 1.2, col = "blue")
plot(Speed, Distance,
     panel.first = lines(stats::lowess(Speed, Distance), lty = "dashed"),
     pch = 0, cex = 1.2, col = "blue")

## Show the different plot types
x <- 0:12
y <- sin(pi/5 * x)
op <- par(mfrow = c(3,3), mar = .1+ c(2,2,3,1))
for (tp in c("p","l","b","c","o","h","s","S","n")) {
    plot(y ~ x, type = tp, main = paste0("plot(*, type = ", tp, ")")
    if(tp == "S") {
        lines(x, y, type = "s", col = "red", lty = 2)
        mtext("lines(*, type = "s", ...)", col = "red", cex = 0.8)
    }
}
par(op)

###--- Log-Log Plot with custom axes
lx <- seq(1, 5, length = 41)
yl <- expression(e^{(-frac(1,2) * (log[10](x))^2)})
y <- exp(-.5*lx^2)
op <- par(mfrow = c(2,1), mar = par("mar")-c(1,0,2,0), mgp = c(2, .7, 0))
plot(10^lx, y, log = "xy", type = "l", col = "purple",
     main = "Log-Log plot", ylab = yl, xlab = "x")
plot(10^lx, y, log = "xy", type = "o", pch = ".", col = "forestgreen",
     main = "Log-Log plot with custom axes", ylab = yl, xlab = "x",
     axes = FALSE, frame.plot = TRUE)
my.at <- 10^c(1:5)
axis(1, at = my.at, labels = formatC(my.at, format = "fg"))
e.y <- -5:-1; at.y <- 10^e.y
axis(2, at = at.y, col.axis = "red", las = 1,
labels = as.expression(lapply(e.y, function(E) bquote(10^.(E)))))
par(op)

plot.design

Plot Univariate Effects of a Design or Model

Description
Plot univariate effects of one or more factors, typically for a designed experiment as analyzed by aov().

Usage
plot.design(x, y = NULL, fun = mean, data = NULL, ..., ylim = NULL, xlab = "Factors", ylab = NULL, main = NULL, ask = NULL, xaxt = par("xaxt"), axes = TRUE, xtick = FALSE)

Arguments
x either a data frame containing the design factors and optionally the response, or a formula or terms object.
y the response, if not given in x.
fun a function (or name of one) to be applied to each subset. It must return one number for a numeric (vector) input.
data data frame containing the variables referenced by x when that is formula-like.
... graphical parameters such as col, see par.
ylim range of y values, as in plot.default.
xlab x axis label, see title.
ylab y axis label with a 'smart' default.
main main title, see title.
ask logical indicating if the user should be asked before a new page is started – in the case of multiple y’s.
xaxt character giving the type of x axis.
axes logical indicating if axes should be drawn.
xtick logical indicating if ticks (one per factor) should be drawn on the x axis.

Details
The supplied function will be called once for each level of each factor in the design and the plot will show these summary values. The levels of a particular factor are shown along a vertical line, and the overall value of fun() for the response is drawn as a horizontal line.

Note
A big effort was taken to make this closely compatible to the S version. However, col (and fg) specifications have different effects.
In S this was a method of the plot generic function for design objects.
Author(s)
Roberto Frisullo and Martin Maechler

References

See Also
interaction.plot for a 'standard graphic' of designed experiments.

Examples
require(stats)
plot.design(warpbreaks) # automatic for data frame with one numeric var.
Form <- breaks ~ wool + tension
summary(fm1 <- aov(Form, data = warpbreaks))
plot.design( Form, data = warpbreaks, col = 2) # same as above

## More than one y :
utils::str(esoph)
plot.design(esoph) ## two plots; if interactive you are "ask"ed

## or rather, compare mean and median:
op <- par(mfcol = 1:2)
plot.design(ncases/ncontrols ~ ., data = esoph, ylim = c(0, 0.8))
plot.design(ncases/ncontrols ~ ., data = esoph, ylim = c(0, 0.8),
        fun = median)
par(op)

Description
This functions implements a scatterplot method for factor arguments of the generic plot function. If y is missing barplot is produced. For numeric y a boxplot is used, and for a factor y a spineplot is shown. For any other type of y the next plot method is called, normally plot.default.

Usage
## S3 method for class 'factor'
plot(x, y, legend.text = NULL, ...)

.plot.formula

Arguments

- **x, y**: numeric or factor. y may be missing.
- **legend.text**: character vector for annotation of y axis in the case of a factor y: defaults to `levels(y)`. This sets the `yaxlabels` argument of `spineplot`.
- **...**: Further arguments to `barplot`, `boxplot`, `spineplot` or `plot` as appropriate. All of these accept graphical parameters (see `par`) and annotation arguments passed to `title` and `axes = FALSE`. None accept `type`.

See Also

- `plot.default`, `plot.formula`, `barplot`, `boxplot`, `spineplot`.

Examples

```r
require(grDevices)

plot(weight ~ group, data = PlantGrowth) # numeric vector ~ factor
plot(cut(weight, 2) ~ group, data = PlantGrowth) # factor ~ factor
### passing "..." to spineplot() eventually:
plot(cut(weight, 3) ~ group, data = PlantGrowth,
col = hcl(c(0, 120, 240), 50, 70))
plot(PlantGrowth$group, axes = FALSE, main = "no axes") # extremely silly
```

Description

Specify a scatterplot or add points, lines, or text via a formula.

Usage

```r
### S3 method for class 'formula'
plot(formula, data = parent.frame(), ..., subset,
ylab = varnames[response], ask = dev.interactive())

### S3 method for class 'formula'
points(formula, data = parent.frame(), ..., subset)

### S3 method for class 'formula'
lines(formula, data = parent.frame(), ..., subset)

### S3 method for class 'formula'
text(formula, data = parent.frame(), ..., subset)
```
Arguments

- **formula**: a formula, such as y ~ x.
- **data**: a data.frame (or list) from which the variables in formula should be taken. A matrix is converted to a data frame.
- **...**: Arguments to be passed to or from other methods. horizontal = TRUE is also accepted.
- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.
- **ylab**: the y label of the plot(s).
- **ask**: logical, see par.

Details

For the lines, points and text methods the formula should be of the form y ~ x or y ~ 1 with a left-hand side and a single term on the right-hand side. The plot method accepts other forms discussed later in this section.

Both the terms in the formula and the ... arguments are evaluated in data enclosed in parent.frame() if data is a list or a data frame. The terms of the formula and those arguments in ... that are of the same length as data are subjected to the subsetting specified in subset. A plot against the running index can be specified as plot(y ~ 1).

If the formula in the plot method contains more than one term on the right-hand side, a series of plots is produced of the response against each non-response term.

For the plot method the formula can be of the form ~ z + y + z: the variables specified on the right-hand side are collected into a data frame, subsetted if specified, and displayed by plot.data.frame.

Missing values are not considered in these methods, and in particular cases with missing values are not removed.

If y is an object (i.e., has a class attribute) then plot.formula looks for a plot method for that class first. Otherwise, the class of x will determine the type of the plot. For factors this will be a parallel boxplot, and argument horizontal = TRUE can be specified (see boxplot).

Note that some arguments will need to be protected from premature evaluation by enclosing them in quote: currently this is done automatically for main, sub and xlab. For example, it is needed for the panel.first and panel.last arguments passed to plot.default.

Value

These functions are invoked for their side effect of drawing on the active graphics device.

See Also

plot.default, points, lines, plot.factor.

Examples

```r
op <- par(mfrow = c(2,1))
plot(Ozone ~ Wind, data = airquality, pch = as.character(Month))
plot(Ozone ~ Wind, data = airquality, pch = as.character(Month),
     subset = Month != 7)
par(op)

## text.formula() can be very natural:
```

```r
wb <- within(warpbreaks, {
  time <- seq_along(breaks); W.T <- wool:tension
})
plot(breaks ~ time, data = wb, type = "b")
text(breaks ~ time, data = wb, label = W.T, col = 1+as.integer(wool))
```

**plot.histogram**  
**Plot Histograms**

**Description**

These are methods for objects of class "histogram", typically produced by `hist`.

**Usage**

```r
## S3 method for class 'histogram'
plot(x, freq = equidist, density = NULL, angle = 45,
col = NULL, border = par("fg"), lty = NULL,
main = paste("Histogram of",
  paste(x$xname, collapse = "\n")),
sub = NULL, xlab = x$xname, ylab,
xlim = range(x$breaks), ylim = NULL,
axes = TRUE, labels = FALSE, add = FALSE,
ann = TRUE, ...) 
```

```r
## S3 method for class 'histogram'
lines(x, ...)
```

**Arguments**

- `x`: A histogram object, or a list with components density, mid, etc, see `hist` for information about the components of `x`.
- `freq`: Logical; if TRUE, the histogram graphic is to present a representation of frequencies, i.e, `x$counts`; if FALSE, relative frequencies (probabilities), i.e., `x$density`, are plotted. The default is true for equidistant breaks and false otherwise.
- `col`: A colour to be used to fill the bars. The default of NULL yields unfilled bars.
- `border`: The color of the border around the bars.
- `angle`, `density`: Select shading of bars by lines: see `rect`.
- `lty`: The line type used for the bars, see also `lines`.
- `main`, `sub`, `xlab`, `ylab`: These arguments to `title` have useful defaults here.
- `xlim`, `ylim`: The range of x and y values with sensible defaults.
- `axes`: Logical, indicating if axes should be drawn.
- `labels`: Logical or character. Additionally draw labels on top of bars, if not FALSE; if TRUE, draw the counts or rounded densities; if labels is a character, draw itself.
- `add`: Logical. If TRUE, only the bars are added to the current plot. This is what `lines.histogram(*)` does.
- `ann`: Logical. Should annotations (titles and axis titles) be plotted?
- `...`: Further graphical parameters to `title` and `axis`.
plot.raster

Details

`lines.histogram(*)` is the same as `plot.histogram(*, add = TRUE)`.

See Also

`hist`, `stem`, `density`.

Examples

```r
(wwt <- hist(women$weight, nclass = 7, plot = FALSE))
plot(wwt, labels = TRUE) # default main & xlab using wwt$xname
plot(wwt, border = "dark blue", col = "light blue",
     main = "Histogram of 15 women's weights", xlab = "weight [pounds]"
)
```

```r
## Fake "lines" example, using non-default labels:
w2 <- wwt; w2$counts <- w2$counts - 1
lines(w2, col = "Midnight Blue", labels = ifelse(w2$counts, "> 1", "1"))
```

plot.raster  Plotting Raster Images

Description

This function implements a `plot` method for raster images.

Usage

```r
## S3 method for class 'raster'
plot(x, y, 
     xlim = c(0, ncol(x)), ylim = c(0, nrow(x)),
     xaxs = "i", yaxs = "i",
     asp = 1, add = FALSE, ...)
```

Arguments

- `x, y` raster. `y` will be ignored.
- `xlim, ylim` Limits on the plot region (default from dimensions of the raster).
- `xaxs, yaxs` Axis interval calculation style (default means that raster fills plot region).
- `asp` Aspect ratio (default retains aspect ratio of the raster).
- `add` Logical indicating whether to simply add raster to an existing plot.
- `...` Further arguments to the `rasterImage` function.

See Also

`plot.default, rasterImage`.

plot.raster

Plotting Raster Images

Description

This function implements a `plot` method for raster images.

Usage

```r
## S3 method for class 'raster'
plot(x, y, 
     xlim = c(0, ncol(x)), ylim = c(0, nrow(x)),
     xaxs = "i", yaxs = "i",
     asp = 1, add = FALSE, ...)
```

Arguments

- `x, y` raster. `y` will be ignored.
- `xlim, ylim` Limits on the plot region (default from dimensions of the raster).
- `xaxs, yaxs` Axis interval calculation style (default means that raster fills plot region).
- `asp` Aspect ratio (default retains aspect ratio of the raster).
- `add` Logical indicating whether to simply add raster to an existing plot.
- `...` Further arguments to the `rasterImage` function.

`hist`, `stem`, `density`.

Examples

```r
(wwt <- hist(women$weight, nclass = 7, plot = FALSE))
plot(wwt, labels = TRUE) # default main & xlab using wwt$xname
plot(wwt, border = "dark blue", col = "light blue",
     main = "Histogram of 15 women's weights", xlab = "weight [pounds]"
)
```

```r
## Fake "lines" example, using non-default labels:
w2 <- wwt; w2$counts <- w2$counts - 1
lines(w2, col = "Midnight Blue", labels = ifelse(w2$counts, "> 1", "1"))
```
Examples

```r
require(grDevices)

r <- as.raster(c(0.5, 1, 0.5))
plot(r)
# additional arguments to rasterImage()
plot(r, interpolate=FALSE)
# distort
plot(r, asp=NA)
# fill page
op <- par(mar=rep(0, 4))
plot(r, asp=NA)
par(op)
# normal annotations work
plot(r, asp=NA)
box()
title(main="This is my raster")
# add to existing plot
plot()
plot(r, add=TRUE)
```

---

plot.table  

Plot Methods for \textit{table} Objects

Description

This is a method of the generic \texttt{plot} function for (contingency) \texttt{table} objects. Whereas for two- and more dimensional tables, a \texttt{mosaicplot} is drawn, one-dimensional ones are plotted as bars.

Usage

```r
## S3 method for class 'table'
plot(x, type = "h", ylim = c(0, max(x)), lwd = 2,
    xlab = NULL, ylab = NULL, frame.plot = is.num, ...)

## S3 method for class 'table'
points(x, y = NULL, type = "h", lwd = 2, ...)

## S3 method for class 'table'
lines(x, y = NULL, type = "h", lwd = 2, ...)
```

Arguments

- \texttt{x}  
a \texttt{table} (like) object.
- \texttt{y}  
Must be \texttt{NULL}: there to protect against incorrect calls.
- \texttt{type}  
plotting type.
- \texttt{ylim}  
range of y-axis.
- \texttt{lwd}  
line width for bars when \texttt{type = "h"} is used in the 1D case.
- \texttt{xlab}, \texttt{ylab}  
x- and y-axis labels.
- \texttt{frame.plot}  
logical indicating if a frame (\texttt{box}) should be drawn in the 1D case. Defaults to true when \texttt{x} has \texttt{dimnames} coerce-able to numbers.
- ...  
further graphical arguments, see \texttt{plot.default}. \texttt{axes = FALSE} is accepted.
plot.window

Set up World Coordinates for Graphics Window

Description

This function sets up the world coordinate system for a graphics window. It is called by higher level functions such as plot.default (after plot.new).

Usage

plot.window(xlim, ylim, log = "", asp = NA, ...)

Arguments

xlim, ylim numeric vectors of length 2, giving the x and y coordinates ranges.
log character; indicating which axes should be in log scale.
asp numeric, giving the aspect ratio y/x, see ‘Details’.
... further graphical parameters as in par. The relevant ones are xaxs, yaxs and lab.

Details

asp: If asp is a finite positive value then the window is set up so that one data unit in the x direction is equal in length to asp × one data unit in the y direction.
Note that in this case, par("usr") is no longer determined by, e.g., par("xaxs"), but rather by asp and the device’s aspect ratio. (See what happens if you interactively resize the plot device after running the example below!)
The special case asp == 1 produces plots where distances between points are represented accurately on screen. Values with asp > 1 can be used to produce more accurate maps when using latitude and longitude.

Note that the coordinate ranges will be extended by 4% if the appropriate graphical parameter xaxs or yaxs has value "r" (which is the default).

To reverse an axis, use xlim or ylim of the form c(hi, lo).

The function attempts to produce a plausible set of scales if one or both of xlim and ylim is of length one or the two values given are identical, but it is better to avoid that case.

Examples

## 1-d tables
(Poisss.tab <- table(N = stats::rpois(200, lambda = 5)))
plot(Poisss.tab, main = "plot(table(rpois(200, lambda = 5)))")

plot(table(state.division))

## 4-D :
plot(Titanic, main = "plot(Titanic, main= *)")

See Also

plot.factor, the plot method for factors.
Usually, one should rather use the higher-level functions such as `plot`, `hist`, `image`, ... instead and refer to their help pages for explanation of the arguments.

A side-effect of the call is to set up the `usr`, `xaxp` and `yaxp` graphical parameters. (It is for the latter two that `lab` is used.)

**See Also**

- `xy.coords`, `plot.xy`, `plot.default`
- `par` for the graphical parameters mentioned.

**Examples**

```r
##--- An example for the use of 'asp':
require(stats) # normally loaded
loc <- cmdscale(eurodist)
rx <- range(x <- loc[,1])
ry <- range(y <- -loc[,2])
plot(x, y, type = "n", asp = 1, xlab = "", ylab = "")
abline(h = pretty(rx, 10), v = pretty(ry, 10), col = "lightgray")
text(x, y, labels(eurodist), cex = 0.8)
```

---

**plot.xy**

### Basic Internal Plot Function

**Description**

This is *the* internal function that does the basic plotting of points and lines. Usually, one should rather use the higher level functions instead and refer to their help pages for explanation of the arguments.

**Usage**

```r
plot.xy(xy, type, pch = par("pch"), lty = par("lty"),
        col = par("col"), bg = NA,
        cex = 1, lwd = par("lwd"), ...)
```

**Arguments**

- `xy`  A four-element list as results from `xy.coords`.
- `type`  1 character code: see `plot.default`. NULL is accepted as a synonym for "p".
- `pch`  character or integer code for kind of points, see `points.default`.
- `lty`  line type code, see `lines`.
- `col`  color code or name, see `colors`, `palette`. Here NULL means colour 0.
- `bg`  background (fill) color for the open plot symbols 21:25: see `points.default`.
- `cex`  character expansion.
- `lwd`  line width, also used for (non-filled) plot symbols, see `lines` and `points`.
- `...`  further graphical parameters such as `xpd`, `lend`, `ljoin` and `lmitre`.
points

Description

points is a generic function to draw a sequence of points at the specified coordinates. The specified character(s) are plotted, centered at the coordinates.

Usage

points(x, ...)  
## Default S3 method:
points(x, y = NULL, type = "p", ...)  

Arguments

x, y
coordinate vectors of points to plot.

type
character indicating the type of plotting; actually any of the types as in plot.default.

...  
Further graphical parameters may also be supplied as arguments. See ‘Details’.

Details

The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, a time series, .... See xy.coords. If supplied separately, they must be of the same length.

Graphical parameters commonly used are

- **pch**: plotting ‘character’, i.e., symbol to use. This can either be a single character or an integer code for one of a set of graphics symbols. The full set of S symbols is available with pch = 0:18, see the examples below. (NB: R uses circles instead of the octagons used in S.)
  - Value pch = "." (equivalently pch = 46) is handled specially. It is a rectangle of side 0.01 inch (scaled by cex). In addition, if cex = 1 (the default), each side is at least one pixel (1/72 inch on the pdf, postscript and xfig devices).
  - For other text symbols, cex = 1 corresponds to the default fontsize of the device, often specified by an argument pointsize. For pch in 0:25 the default size is about 75% of the character height (see par("cin")).
co1  color code or name, see \texttt{par}.
bg  background (fill) color for the open plot symbols given by \texttt{pch = 21:25}.
cex  character (or symbol) expansion: a numerical vector. This works as a multiple of \texttt{par("cex")}.
lwd  line width for drawing symbols see \texttt{par}.

Others less commonly used are \texttt{ltty} and \texttt{lwd} for types such as "b" and "1".
The \texttt{graphical parameters} \texttt{pch}, \texttt{co1}, \texttt{bg}, \texttt{cex} and \texttt{lwd} can be vectors (which will be recycled as needed) giving a value for each point plotted. If lines are to be plotted (e.g., for \texttt{type = "b"}) the first element of \texttt{lwd} is used.

Points whose \texttt{x}, \texttt{y}, \texttt{pch}, \texttt{co1} or \texttt{cex} value is \texttt{NA} are omitted from the plot.

\texttt{'pch' values}

Values of \texttt{pch} are stored internally as integers. The interpretation is

- \texttt{NA_integer_}: no symbol.
- 0:18: S-compatible vector symbols.
- 19:25: further \texttt{R} vector symbols.
- 26:31: unused (and ignored).
- 32:127: ASCII characters.
- 128:255 native characters \textit{only in a single-byte locale and for the symbol font}. (128:159 are only used on Windows.)
- \texttt{-32...}: Unicode code point (where supported).

Note that unlike S (which uses octagons), symbols 1, 10, 13 and 16 use circles. The filled shapes 15:18 do not include a border.

\begin{verbatim}
  0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25
    □ ○ △ + × ◊ ▽ ◉ ◊ ◇ ◌ ◍ ■ ▲ ◆ ● ○ ● ◇ ◆ △ ▽
\end{verbatim}

The following \texttt{R} plotting symbols are can be obtained with \texttt{pch = 19:25}: those with 21:25 can be colored and filled with different colors: \texttt{co1} gives the border color and \texttt{bg} the background color (which is ”grey” in the figure)

- \texttt{pch = 19}: solid circle,
- \texttt{pch = 20}: bullet (smaller solid circle, 2/3 the size of 19),
- \texttt{pch = 21}: filled circle,
- \texttt{pch = 22}: filled square,
- \texttt{pch = 23}: filled diamond,
- \texttt{pch = 24}: filled triangle point-up,
- \texttt{pch = 25}: filled triangle point down.

Note that all of these both fill the shape and draw a border. Some care in interpretation is needed when semi-transparent colours are used for both fill and border (and the result might be device-specific and even viewer-specific for \texttt{pdf}).

The difference between \texttt{pch = 16} and \texttt{pch = 19} is that the latter uses a border and so is perceptibly larger when \texttt{lwd} is large relative to \texttt{cex}.
Values \( \text{pch} = 26:31 \) are currently unused and \( \text{pch} = 32:127 \) give the ASCII characters. In a single-byte locale \( \text{pch} = 128:255 \) give the corresponding character (if any) in the locale’s character set. Where supported by the OS, negative values specify a Unicode code point, so e.g. \(-0x2642\) is a ‘male sign’ and \(-0x20AC\) is the Euro.

A character string consisting of a single character is converted to an integer: \( 32:127 \) for ASCII characters, and usually to the Unicode code point otherwise. (In non-Latin-1 single-byte locales, \( 128:255 \) will be used for 8-bit characters.)

If \( \text{pch} \) supplied is a logical, integer or character \( \text{NA} \) or an empty character string the point is omitted from the plot.

If \( \text{pch} \) is \( \text{NULL} \) or otherwise of length 0, \( \text{par("pch")} \) is used.

If the symbol font (\( \text{par(font = 5)} \)) is used, numerical values should be used for \( \text{pch} \): the range is \( c(32:126, \ 160:254) \) in all locales (but 240 is not defined (used for ‘apple’ on macOS) and 160, Euro, may not be present).

Note

A single-byte encoding may include the characters in \( \text{pch} = 128:255 \), and if it does, a font may not include all (or even any) of them.

Not all negative numbers are valid as Unicode code points, and no check is done. A display device is likely to use a rectangle for (or omit) Unicode code points which are invalid or for which it does not have a glyph in the font used.

What happens for very small or zero values of \( \text{cex} \) is device-dependent: symbols or characters may become invisible or they may be plotted at a fixed minimum size. Circles of zero radius will not be plotted.

try(TestChars(-1, font = 2))  # bold

---

**polygon**  

**Polygon Drawing**

**Description**

polygon draws the polygons whose vertices are given in x and y.

**Usage**

```r
polygon(x, y = NULL, density = NULL, angle = 45, 
        border = NULL, col = NA, lty = par("lty"),
        ..., fillOddEven = FALSE)
```

**Arguments**

- **x, y**  
  - vectors containing the coordinates of the vertices of the polygon.

- **density**  
  - the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading nor filling whereas negative values and NA suppress shading (and so allow color filling).

- **angle**  
  - the slope of shading lines, given as an angle in degrees (counter-clockwise).

- **col**  
  - the color for filling the polygon. The default, NA, is to leave polygons unfilled, unless density is specified. (For back-compatibility, NULL is equivalent to NA.) If density is specified with a positive value this gives the color of the shading lines.

- **border**  
  - the color to draw the border. The default, NULL, means to use `par("fg")`. Use border = NA to omit borders.
  - For compatibility with S, border can also be logical, in which case FALSE is equivalent to NA (borders omitted) and TRUE is equivalent to NULL (use the foreground colour).

- **lty**  
  - the line type to be used, as in `par`.

- **...**  
  - graphical parameters such as `xpd`, `lend`, `ljoin` and `mitre` can be given as arguments.

- **fillOddEven**  
  - logical controlling the polygon shading mode: see below for details. Default FALSE.

**Details**

The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, .... See `xy.coords`.

It is assumed that the polygon is to be closed by joining the last point to the first point.

The coordinates can contain missing values. The behaviour is similar to that of `lines`, except that instead of breaking a line into several lines, NA values break the polygon into several complete polygons (including closing the last point to the first point). See the examples below.
When multiple polygons are produced, the values of density, angle, col, border, and lty are recycled in the usual manner.

Shading of polygons is only implemented for linear plots: if either axis is on log scale then shading is omitted, with a warning.

**Bugs**

Self-intersecting polygons may be filled using either the “odd-even” or “non-zero” rule. These fill a region if the polygon border encircles it an odd or non-zero number of times, respectively. Shading lines are handled internally by R according to the fillOddEven argument, but device-based solid fills depend on the graphics device. The windows, pdf and postscript devices have their own fillOddEven argument to control this.

**Author(s)**

The code implementing polygon shading was donated by Kevin Buhr <buhr@stat.wisc.edu>.

# Line-shaded polygons
plot(c(1, 9), 1:2, type = "n")
polygon(1:9, c(2,1,2,1,NA,2,1,2,1),
density = c(10, 20), angle = c(-45, 45))

polypath

Path Drawing

Description

path draws a path whose vertices are given in x and y.

Usage

polypath(x, y = NULL,
border = NULL, col = NA, lty = par("lty"),
rule = "winding", ...)

Arguments

x, y    vectors containing the coordinates of the vertices of the path.
col    the color for filling the path. The default, NA, is to leave paths unfilled, unless density is specified. (For back-compatibility, NULL is equivalent to NA.) If density is specified with a positive value this gives the color of the shading lines.
border   the color to draw the border. The default, NULL, means to use par("fg"). Use border = NA to omit borders. For compatibility with S, border can also be logical, in which case FALSE is equivalent to NA (borders omitted) and TRUE is equivalent to NULL (use the foreground colour).
lty    the line type to be used, as in par.
rule   character value specifying the path fill mode: either "winding" or "evenodd".
...   graphical parameters such as xpd, lend, ljoin and lmitre can be given as arguments.

Details

The coordinates can be passed in a plotting structure (a list with x and y components), a two-column matrix, .... See xy.coords.

It is assumed that the path is to be closed by joining the last point to the first point.

The coordinates can contain missing values. The behaviour is similar to that of polygon, except that instead of breaking a polygon into several polygons, NA values break the path into several sub-paths (including closing the last point to the first point in each sub-path). See the examples below.
The distinction between a path and a polygon is that the former can contain holes, as interpreted by the fill rule; these fill a region if the path border encircles it an odd or non-zero number of times, respectively.

Hatched shading (as implemented for polygon()) is not (currently) supported.

Not all graphics devices support this function: for example xfig and pictex do not.

  "Overlapping rectangles, one clockwise, other anti-clockwise")

par(op)
rasterImage

**Draw One or More Raster Images**

**Description**

rasterImage draws a raster image at the given locations and sizes.

**Usage**

rasterImage(image,  
  xleft, ybottom, xright, ytop,  
  angle = 0, interpolate = TRUE, ...)

**Arguments**

- **image**
  a raster object, or an object that can be coerced to one by as.raster.
- **xleft**
  a vector (or scalar) of left x positions.
- **ybottom**
  a vector (or scalar) of bottom y positions.
- **xright**
  a vector (or scalar) of right x positions.
- **ytop**
  a vector (or scalar) of top y positions.
- **angle**
  angle of rotation (in degrees, anti-clockwise from positive x-axis, about the bottom-left corner).
- **interpolate**
  a logical vector (or scalar) indicating whether to apply linear interpolation to the image when drawing.
- **...**
  graphical parameters.

**Details**

The positions supplied, i.e., xleft, ..., are relative to the current plotting region. If the x-axis goes from 100 to 200 then xleft should be larger than 100 and xright should be less than 200. The position vectors will be recycled to the length of the longest.

Plotting raster images is not supported on all devices and may have limitations where supported, for example (e.g., for postscript and X11(type = "Xlib")) is restricted to opaque colors). Problems with the rendering of raster images have been reported by users of windows() devices under Remote Desktop, at least under its default settings.

You should not expect a raster image to be re-sized when an on-screen device is re-sized: whether it is is device-dependent.

**See Also**

rect, polygon, and segments and others for flexible ways to draw shapes.

dev.capabilities to see if it is supported.
Examples

```r
require(grDevices)
## set up the plot region:
op <- par(bg = "thistle")
plot(c(100, 250), c(300, 450), type = "n", xlab = "", ylab = "")
image <- as.raster(matrix(0:1, ncol = 5, nrow = 3))
rasterImage(image, 100, 300, 150, 350, interpolate = FALSE)
rasterImage(image, 100, 400, 150, 450)
rasterImage(image, 200, 300, 200 + xinch(.5), 300 + yinch(.3),
            interpolate = FALSE)
rasterImage(image, 200, 400, 250, 450, angle = 15, interpolate = FALSE)
par(op)
```

---

**rect**

**Draw One or More Rectangles**

Description

rect draws a rectangle (or sequence of rectangles) with the given coordinates, fill and border colors.

Usage

```r
rect(xleft, ybottom, xright, ytop, density = NULL, angle = 45,
     col = NA, border = NULL, lty = par("lty"), lwd = par("lwd"),
     ...)```

Arguments

- `xleft` a vector (or scalar) of left x positions.
- `ybottom` a vector (or scalar) of bottom y positions.
- `xright` a vector (or scalar) of right x positions.
- `ytop` a vector (or scalar) of top y positions.
- `density` the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading lines whereas negative values (and NA) suppress shading (and so allow color filling).
- `angle` angle (in degrees) of the shading lines.
- `col` color(s) to fill or shade the rectangle(s) with. The default NA (or also NULL) means do not fill, i.e., draw transparent rectangles, unless density is specified.
- `border` color for rectangle border(s). The default means par("fg"). Use border = NA to omit borders. If there are shading lines, border = TRUE means use the same colour for the border as for the shading lines.
- `lty` line type for borders and shading; defaults to "solid".
- `lwd` line width for borders and shading. Note that the use of lwd = 0 (as in the examples) is device-dependent.
- `...` graphical parameters such as xpd, lend, ljoin and lmitre can be given as arguments.
rug

Add a Rug to a Plot

Description

Adds a rug representation (1-d plot) of the data to the plot.

Details

The positions supplied, i.e., xleft, ..., are relative to the current plotting region. If the x-axis goes from 100 to 200 then xleft must be larger than 100 and xright must be less than 200. The position vectors will be recycled to the length of the longest.

It is a graphics primitive used in hist, barplot, legend, etc.

See Also

box for the standard box around the plot; polygon and segments for flexible line drawing.

par for how to specify colors.

Examples

```r
require(grDevices)
## set up the plot region:
op <- par(bg = "thistle")
plot(c(100, 250), c(300, 450), type = "n", xlab = "", ylab = "",
     main = "2 x 11 rectangles; "rect(100+i,300+i, 150+i,380+i)"")
i <- 4*(0:10)
## draw rectangles with bottom left (100, 300)+i
## and top right (150, 380)+i
rect(100+i, 300+i, 150+i, 380+i, col = rainbow(11, start = 0.7, end = 0.1))
rect(240-i, 320+i, 250-i, 410+i, col = heat.colors(11), lwd = i/5)
## Background alternating ( transparent / "bg" ) :
j <- 10*(0:5)
rect(125+j, 360+j, 141+j, 405+j/2, col = c(NA,0),
     border = "gold", lwd = 2)
rect(125+j, 296+j/2, 141+j, 331+j/5, col = c(NA,"midnightblue"))
mtext("+ 2 x 6 rect(*, col = c(NA,0)) and col = c(NA,"m..blue\"))")
## an example showing colouring and shading
plot(c(100, 200), c(300, 450), type = "n", xlab = "", ylab = ")
rect(100, 300, 125, 350) # transparent
rect(100, 400, 125, 450, col = "green", border = "blue") # coloured
rect(115, 375, 150, 425, col = par("bg"), border = "transparent")
rect(150, 300, 175, 350, density = 10, border = "red")
rect(150, 400, 175, 450, density = 30, col = "blue",
     angle = -30, border = "transparent")
legend(180, 450, legend = 1:4, fill = c(NA, "green", par("fg"), "blue"),
       density = c(NA, NA, 10, 30), angle = c(NA, NA, 10, -30))
par(op)
```
Usage

```
rug(x, ticksize = 0.03, side = 1, lwd = 0.5, col = par("fg"),
    quiet = getOption("warn") < 0, ...)```

Arguments

- `x`: A numeric vector
- `ticksize`: The length of the ticks making up the ‘rug’. Positive lengths give inwards ticks.
- `side`: On which side of the plot box the rug will be plotted. Normally 1 (bottom) or 3 (top).
- `lwd`: The line width of the ticks. Some devices will round the default width up to 1.
- `col`: The colour the ticks are plotted in.
- `quiet`: logical indicating if there should be a warning about clipped values.
- `...`: further arguments, passed to `axis`, such as `line` or `pos` for specifying the location of the rug.

Details

Because of the way `rug` is implemented, only values of `x` that fall within the plot region are included. There will be a warning if any finite values are omitted, but non-finite values are omitted silently.

References

See Also

- `jitter` which you may want for ties in `x`.

Examples

```
require(stats) # both 'density' and its default method
with(faithful, {
    plot(density(eruptions, bw = 0.15))
    rug(eruptions)
    rug(jitter(eruptions, amount = 0.01), side = 3, col = "light blue")
})
```

Description

`split.screen` defines a number of regions within the current device which can, to some extent, be treated as separate graphics devices. It is useful for generating multiple plots on a single device. Screens can themselves be split, allowing for quite complex arrangements of plots. `screen` is used to select which screen to draw in. `erase.screen` is used to clear a single screen, which it does by filling with the background colour. `close.screen` removes the specified screen definition(s).
split.screen(figs, screen, erase = TRUE)
screen(n = , new = TRUE)
erase.screen(n = )
close.screen(n, all.screens = FALSE)

Arguments

figs  A two-element vector describing the number of rows and the number of columns in a screen matrix or a matrix with 4 columns. If a matrix, then each row describes a screen with values for the left, right, bottom, and top of the screen (in that order) in NDC units, that is 0 at the lower left corner of the device surface, and 1 at the upper right corner.

screen A number giving the screen to be split. It defaults to the current screen if there is one, otherwise the whole device region.

erase logical: should be selected screen be cleared?

n A number indicating which screen to prepare for drawing (screen), erase (erase.screen), or close (close.screen). (close.screen will accept a vector of screen numbers.)

new A logical value indicating whether the screen should be erased as part of the preparation for drawing in the screen.

all.screens A logical value indicating whether all of the screens should be closed.

Details

The first call to split.screen places R into split-screen mode. The other split-screen functions only work within this mode. While in this mode, certain other commands should be avoided (see the Warnings section below). Split-screen mode is exited by the command close.screen(all = TRUE).

If the current screen is closed, close.screen sets the current screen to be the next larger screen number if there is one, otherwise to the first available screen.

Value

split.screen returns a vector of screen numbers for the newly-created screens. With no arguments, split.screen returns a vector of valid screen numbers.

screen invisibly returns the number of the selected screen. With no arguments, screen returns the number of the current screen.

close.screen returns a vector of valid screen numbers.

screen, erase.screen, and close.screen all return FALSE if R is not in split-screen mode.

Warnings

The recommended way to use these functions is to completely draw a plot and all additions (i.e., points and lines) to the base plot, prior to selecting and plotting on another screen. The behavior associated with returning to a screen to add to an existing plot is unpredictable and may result in problems that are not readily visible.

These functions are totally incompatible with the other mechanisms for arranging plots on a device: par(mfrow), par(mfcol) and layout().
The functions are also incompatible with some plotting functions, such as `coplot`, which make use of these other mechanisms.

`erase.screen` will appear not to work if the background colour is transparent (as it is by default on most devices).

`par`, `layout`, `Devices`, `dev.*`

**Examples**

```r
if (interactive()) {
  par(bg = "white")  # default is likely to be transparent
  split.screen(c(2, 1))  # split display into two screens
  split.screen(c(1, 3), screen = 2)  # now split the bottom half into 3
  screen(1)  # prepare screen 1 for output
  plot(10:1)
  screen(4)  # prepare screen 4 for output
  plot(10:1)
  close.screen(all = TRUE)  # exit split-screen mode
  split.screen(c(2, 1))  # split display into two screens
  split.screen(c(1, 2), 2)  # split bottom half in two
  plot(1:10)  # screen 3 is active, draw plot
  erase.screen()  # forgot label, erase and redraw
  plot(1:10, ylab = "ylab 3")
  screen(1)  # prepare screen 1 for output
  plot(1:10)
  screen(4)  # prepare screen 4 for output
  plot(1:10, ylab = "ylab 4")
  screen(1, FALSE)  # return to screen 1, but do not clear
  plot(10:1, axes = FALSE, lty = 2, ylab = "")  # overlay second plot
  axis(4)  # add tic marks to right-hand axis
  title("Plot 1")
  close.screen(all = TRUE)  # exit split-screen mode
}
```

---

**segments**

*Add Line Segments to a Plot*

**Description**

Draw line segments between pairs of points.

**Usage**

```r
segments(x0, y0, x1 = x0, y1 = y0, 
  col = par("fg"), lty = par("lty"), lwd = par("lwd"),
  ...)
```
smoothScatter

Arguments

x0, y0 coordinates of points from which to draw.
x1, y1 coordinates of points to which to draw. At least one must be supplied.
col, lty, lwd graphical parameters as in par, possibly vectors. NA values in col cause the segment to be omitted.
... further graphical parameters (from par), such as xpd and the line characteristics lend, ljoin and lmitre.

Details

For each i, a line segment is drawn between the point (x0[i], y0[i]) and the point (x1[i], y1[i]). The coordinate vectors will be recycled to the length of the longest.

The graphical parameters col, lty and lwd can be vectors of length greater than one and will be recycled if necessary.

arrows, polygon for slightly easier and less flexible line drawing, and lines for the usual polygons.

Examples

x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x, y); x <- x[i]; y <- y[i]
plot(x, y, main = "arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1) # one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col= 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col= 'pink')

smoothScatter

Scatterplots with Smoothed Densities Color Representation

Description

smoothScatter produces a smoothed color density representation of a scatterplot, obtained through a (2D) kernel density estimate.

Usage

smoothScatter(x, y = NULL, nbin = 128, bandwidth,
             colramp = colorRampPalette(c("white", blues9)),
nrpoints = 100, ret.selection = FALSE,
pch = ".", cex = 1, col = "black",
transformation = function(x) x^.25,
postPlotHook = box,
xlab = NULL, ylab = NULL, xlim, ylim,
xaxs = par("xaxs"), yaxs = par("yaxs"), ...)
smoothScatter

Arguments

- **x, y**: the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function `xy.coords` for details. If supplied separately, they must be of the same length.

- **nbin**: numeric vector of length one (for both directions) or two (for x and y separately) specifying the number of equally spaced grid points for the density estimation; used as `gridsize` in `bkde2D()`.

- **bandwidth**: numeric vector (length 1 or 2) of smoothing bandwidth(s). If missing, a more or less useful default is used. Bandwidth is subsequently passed to function `bkde2D`.

- **colramp**: function accepting an integer `n` as an argument and returning `n` colors.

- **nrpoints**: number of points to be superimposed on the density image. The first `nrpoints` points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose `nrpoints = Inf`.

- **ret.selection**: logical indicating to return the ordered indices of “low density” points if `nrpoints > 0`.

- **pch, cex, col**: arguments passed to `points`, when `nrpoints > 0`: point symbol, character expansion factor and color, see also `par`.

- **transformation**: function mapping the density scale to the color scale.

- **postPlotHook**: either `NULL` or a function which will be called (with no arguments) after `image`.

- **xlab, ylab**: character strings to be used as axis labels, passed to `image`.

- **xlim, ylim**: numeric vectors of length 2 specifying axis limits.

- **xaxs, yaxs, ...**: further arguments passed to `image`, e.g., `add=TRUE` or `useRaster=TRUE`.

Details

`smoothScatter` produces a smoothed version of a scatter plot. Two dimensional (kernel density) smoothing is performed by `bkde2D` from package `KernSmooth`. See the examples for how to use this function together with `pairs`.

Value

If `ret.selection` is true, a vector of integers of length `nrpoints` (or smaller, if there are less finite points inside `xlim` and `ylim`) with the indices of the low-density points drawn, ordered with lowest density first.

Author(s)

Florian Hahne at FHCRC, originally

See Also

`bkde2D` from package `KernSmooth`; `densCols` which uses the same smoothing computations and `blues9` in package `grDevices`.

`scatter.smooth` adds a `loess` regression smoother to a scatter plot.
Examples

```r
## A largish data set
n <- 10000
x1 <- matrix(rnorm(n), ncol = 2)
x2 <- matrix(rnorm(n, mean = 3, sd = 1.5), ncol = 2)
x <- rbind(x1, x2)
oldpar <- par(mfrow = c(2, 2), mar = .1 + c(3, 3, 1, 1), mgp = c(1.5, 0.5, 0))
smoothScatter(x, nrpoints = 0)
smoothScatter(x)

## a different color scheme:
Lab.palette <- colorRampPalette(c("blue", "orange", "red"), space = "Lab")

i.s <- smoothScatter(x, colramp = Lab.palette,
                     pch = NA, n.selected = 250, ret.selection = TRUE)

## label the 20 very lowest-density points, the "outliers" (with obs.number):
i.20 <- i.s[1:20]
text(x[i.20, ], labels = i.20, cex = 0.75)

## somewhat similar, using identical smoothing computations,
## but considerably less efficient for really large data:
plot(x, col = densCols(x), pch = 20)

## use with pairs:
par(mfrow = c(1, 1))
y <- matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000)
y[, c(2, 4)] <- -y[, c(2, 4)]
pairs(y, panel = function(...) smoothScatter(..., nrpoints = 0, add = TRUE),
     gap = 0.2)
par(oldpar)
```

spineplot  
Spine Plots and Spinograms

Description

Spine plots are a special cases of mosaic plots, and can be seen as a generalization of stacked (or highlighted) bar plots. Analogously, spinograms are an extension of histograms.

Usage

```r
spineplot(x, ...)  
```

```
## Default S3 method:
spineplot(x, y = NULL,
          breaks = NULL, tol.ylab = 0.05, off = NULL,
          ylevels = NULL, col = NULL,
          main = "", xlab = NULL, ylab = NULL,
          xaxlabels = NULL, yaxlabels = NULL,
          xlim = NULL, ylim = c(0, 1), axes = TRUE, ...)  
```
## S3 method for class ‘formula’
spineplot(formula, data = NULL,
  breaks = NULL, tol.ylab = 0.05, off = NULL,
  ylevels = NULL, col = NULL,
  main = “”, xlab = NULL, ylab = NULL,
  xaxlabels = NULL, yaxlabels = NULL,
  xlim = NULL, ylim = c(0, 1), axes = TRUE, …,
  subset = NULL, drop.unused.levels = FALSE)

Arguments

x  an object, the default method expects either a single variable (interpreted to be the explanatory variable) or a 2-way table. See details.

y  a “factor” interpreted to be the dependent variable

formula  a “formula” of type y ~ x with a single dependent “factor” and a single explanatory variable.

data  an optional data frame.

breaks  if the explanatory variable is numeric, this controls how it is discretized. breaks is passed to hist and can be a list of arguments.

tol.ylab  convenience tolerance parameter for y-axis annotation. If the distance between two labels drops under this threshold, they are plotted equidistantly.

off  vertical offset between the bars (in per cent). It is fixed to 0 for spinograms and defaults to 2 for spine plots.

ylevels  a character or numeric vector specifying in which order the levels of the dependent variable should be plotted.

col  a vector of fill colors of the same length as levels(y). The default is to call gray.colors.

main, xlab, ylab  character strings for annotation

xaxlabels, yaxlabels  character vectors for annotation of x and y axis. Default to levels(y) and levels(x), respectively for the spine plot. For xaxlabels in the spinogram, the breaks are used.

xlim, ylim  the range of x and y values with sensible defaults.

axes  logical. If FALSE all axes (including those giving level names) are suppressed.

…  additional arguments passed to rect.

subset  an optional vector specifying a subset of observations to be used for plotting.

drop.unused.levels  should factors have unused levels dropped? Defaults to FALSE.

Details

spineplot creates either a spinogram or a spine plot. It can be called via spineplot(x, y) or spineplot(y ~ x) where y is interpreted to be the dependent variable (and has to be categorical) and x the explanatory variable. x can be either categorical (then a spine plot is created) or numerical (then a spinogram is plotted). Additionally, spineplot can also be called with only a single argument which then has to be a 2-way table, interpreted to correspond to table(x, y).

Both, spine plots and spinograms, are essentially mosaic plots with special formatting of spacing and shading. Conceptually, they plot \( P(y|x) \) against \( P(x) \). For the spine plot (where both \( x \) and \( y \)
are categorical), both quantities are approximated by the corresponding empirical relative frequencies. For the spinogram (where $x$ is numerical), $x$ is first discretized (by calling `hist` with `breaks` argument) and then empirical relative frequencies are taken.

Thus, spine plots can also be seen as a generalization of stacked bar plots where not the heights but the widths of the bars correspond to the relative frequencies of $x$. The heights of the bars then correspond to the conditional relative frequencies of $y$ in every $x$ group. Analogously, spinograms extend stacked histograms.

**Value**

The table visualized is returned invisibly.

stars

Star (Spider/Radar) Plots and Segment Diagrams

Description
Draw star plots or segment diagrams of a multivariate data set. With one single location, also draws
‘spider’ (or ‘radar’) plots.
Usage
stars(x, full = TRUE, scale = TRUE, radius = TRUE,
labels = dimnames(x)[[1]], locations = NULL,
nrow = NULL, ncol = NULL, len = 1,
key.loc = NULL, key.labels = dimnames(x)[[2]],
key.xpd = TRUE,
xlim = NULL, ylim = NULL, flip.labels = NULL,
draw.segments = FALSE,
col.segments = 1:n.seg, col.stars = NA, col.lines = NA,
axes = FALSE, frame.plot = axes,
main = NULL, sub = NULL, xlab = "", ylab = "",
cex = 0.8, lwd = 0.25, lty = par("lty"), xpd = FALSE,
mar = pmin(par("mar"),
1.1+ c(2*axes+ (xlab != ""),
2*axes+ (ylab != ""), 1, 0)),
add = FALSE, plot = TRUE, ...)
Arguments
x

matrix or data frame of data. One star or segment plot will be produced for each
row of x. Missing values (NA) are allowed, but they are treated as if they were 0
(after scaling, if relevant).

full

logical flag: if TRUE, the segment plots will occupy a full circle. Otherwise, they
occupy the (upper) semicircle only.

scale

logical flag: if TRUE, the columns of the data matrix are scaled independently so
that the maximum value in each column is 1 and the minimum is 0. If FALSE,
the presumption is that the data have been scaled by some other algorithm to the
range [0, 1].

radius

logical flag: in TRUE, the radii corresponding to each variable in the data will be
drawn.


Stars

labels vector of character strings for labeling the plots. Unlike the S function stars, no attempt is made to construct labels if labels = NULL.

locations Either two column matrix with the x and y coordinates used to place each of the segment plots; or numeric of length 2 when all plots should be superimposed (for a 'spider plot'). By default, locations = NULL, the segment plots will be placed in a rectangular grid.

nrow, ncol integers giving the number of rows and columns to use when locations is NULL. By default, nrow == ncol, a square layout will be used.

len scale factor for the length of radii or segments.

draw.segments logical. If TRUE draw a segment diagram.

col.segments color vector (integer or character, see par), each specifying a color for one of the segments (variables). Ignored if draw.segments = FALSE.

col.stars color vector (integer or character, see par), each specifying a color for one of the stars (cases). Ignored if draw.segments = TRUE.

col.lines color vector (integer or character, see par), each specifying a color for one of the lines (cases). Ignored if draw.segments = TRUE.

axes logical flag: if TRUE axes are added to the plot.

frame.plot logical flag: if TRUE, the plot region is framed.

main a main title for the plot.

sub a sub title for the plot.

xlab a label for the x axis.

ylab a label for the y axis.

cex character expansion factor for the labels.

lwd line width used for drawing.

lty line type used for drawing.

xpd logical or NA indicating if clipping should be done, see par(xpd = .).

... further arguments, passed to the first call of plot(), see plot.default and to box() if frame.plot is true.

add logical, if TRUE add stars to current plot.

plot logical, if FALSE, nothing is plotted.

Details

Missing values are treated as 0.

Each star plot or segment diagram represents one row of the input x. Variables (columns) start on the right and wind counterclockwise around the circle. The size of the (scaled) column is shown by the distance from the center to the point on the star or the radius of the segment representing the variable.

Only one page of output is produced.
Value

Returns the locations of the plots in a two column matrix, invisibly when plot = TRUE.

Note

This code started life as spatial star plots by David A. Andrews. Prior to R 1.4.1, scaling only shifted the maximum to 1, although documented as here.

## Same as above, but with colored lines instead of filled polygons.
stars(USJudgeRatings, locations = c(0, 0), scale = FALSE, radius = FALSE,
    col.lines = 1:10, key.loc = c(0, 0), main = "US Judges rated")

## 'Radar-Segments'
stars(USJudgeRatings[1:10,], locations = 0:1, scale = FALSE,
    draw.segments = TRUE, col.segments = 0, col.stars = 1:10, key.loc = 0:1,
    main = "US Judges 1-10 ")
palette("default")
stars(cbind(1:16, 10*(16:1)), draw.segments = TRUE,
    main = "A Joke -- do *not* use symbols on 2D data!")

---

**Stem-and-Leaf Plots**

### Description

stem produces a stem-and-leaf plot of the values in x. The parameter scale can be used to expand the scale of the plot. A value of scale = 2 will cause the plot to be roughly twice as long as the default.

### Usage

```r
stem(x, scale = 1, width = 80, atom = 1e-08)
```

### Arguments

- **x**: a numeric vector.
- **scale**: This controls the plot length.
- **width**: The desired width of plot.
- **atom**: a tolerance.

### Details

Infinite and missing values in x are discarded.

### References

### Examples

```r
stem(islands)
stem(log10(islands))
```
stripchart  

I-D Scatter Plots

Description

stripchart produces one dimensional scatter plots (or dot plots) of the given data. These plots are a good alternative to boxplots when sample sizes are small.

Usage

stripchart(x, ...)

## S3 method for class 'formula'
stripchart(x, data = NULL, dlab = NULL, ..., 
subset, na.action = NULL)

## Default S3 method: 
stripchart(x, method = "overplot", jitter = 0.1, offset = 1/3, 
vertical = FALSE, group.names, add = FALSE, 
at = NULL, xlim = NULL, ylim = NULL, 
ylab = NULL, xlab = NULL, dlab = "", glab = "", 
log = "", pch = 0, col = par("fg"), cex = par("cex"), 
axes = TRUE, frame.plot = axes, ...)

Arguments

x  
the data from which the plots are to be produced. In the default method the data can be specified as a single numeric vector, or as list of numeric vectors, each corresponding to a component plot. In the formula method, a symbolic specification of the form \( y \sim g \) can be given, indicating the observations in the vector \( y \) are to be grouped according to the levels of the factor \( g \). NAs are allowed in the data.

data  
a data.frame (or list) from which the variables in x should be taken.

subset  
an optional vector specifying a subset of observations to be used for plotting.

na.action  
a function which indicates what should happen when the data contain NAs. The default is to ignore missing values in either the response or the group.

...  
additional parameters passed to the default method, or by it to plot.window, points, axis and title to control the appearance of the plot.

method  
the method to be used to separate coincident points. The default method "overplot" causes such points to be overplotted, but it is also possible to specify "jitter" to jitter the points, or "stack" have coincident points stacked. The last method only makes sense for very granular data.

jitter  
when method = "jitter" is used, jitter gives the amount of jittering applied.

offset  
when stacking is used, points are stacked this many line-heights (symbol widths) apart.

vertical  
when vertical is TRUE the plots are drawn vertically rather than the default horizontal.
**strwidth**

Plotting Dimensions of Character Strings and Math Expressions

Description

These functions compute the width or height, respectively, of the given strings or mathematical expressions \( s[i] \) on the current plotting device in user coordinates, inches or as fraction of the figure width \( \text{par}("fin") \).

Usage

\[
\text{strwidth}(s, \text{units} = \text{"user"}, \text{cex} = \text{NULL}, \text{font} = \text{NULL}, \text{vfont} = \text{NULL}, \ldots)
\]

\[
\text{strheight}(s, \text{units} = \text{"user"}, \text{cex} = \text{NULL}, \text{font} = \text{NULL}, \text{vfont} = \text{NULL}, \ldots)
\]
Arguments

`s`  
A character or expression vector whose dimensions are to be determined. Other objects are coerced by `as.graphicsAnnot`.

`units`  
A character indicating in which units `s` is measured; should be one of "user", "inches", "figure"; partial matching is performed.

`cex`  
A numeric character expansion factor; multiplied by `par("cex")` yields the final character size; the default NULL is equivalent to 1.

`font, vfont, ...`  
Additional information about the font, possibly including the graphics parameter "family": see `text`.

Details

Note that the ‘height’ of a string is determined only by the number of line feeds ("\n") it contains: it is the (number of line feeds - 1) times the line spacing plus the height of "M" in the selected font. For an expression it is the height of the bounding box as computed by `plotmath`. Thus in both cases it is an estimate of how far above the final baseline the typeset object extends. (It may also extend below the baseline.) The inter-line spacing is controlled by `cex`, `par("lheight")` and the ‘point size’ (but not the actual font in use).

Measurements in "user" units (the default) are only available after `plot.new` has been called – otherwise an error is thrown.

Value

Numeric vector with the same length as `s`, giving the estimate of width or height for each `s[i]`. NA strings are given width and height 0 (as they are not plotted).

`text`, `nchar`

Examples

```r
str.ex <- c("W","w","I",".","WwI.")
op <- par(pty = "s"); plot(1:100, 1:100, type = "n")
sw <- strwidth(str.ex); sw
all.equal(sum(sw[1:4]), sw[5])  # since the last string contains the others
sw.i <- strwidth(str.ex, "inches"); 25.4 * sw.i  # width in [mm]
unique(sw / sw.i)
# constant factor: 1 value
mean(sw.i / strwidth(str.ex, "fig")) / par("fin")[1]  # = 1: are the same

## See how letters fall in classes
## depending on graphics device and font!
all.lett <- c(letters, LETTERS)
shL <- strheight(all.lett, units = "inches") * 72  # 'big points'
table(shL)  # all have same heights ...
mean(shL)/par("cin")[2]  # around 0.6

(swL <- strwidth(all.lett, units = "inches") * 72)  # 'big points'
split(all.lett, factor(round(swL, 2)))
```
sunflowerplot

sumex <- expression(sum(x[i], i=1,n), e^{i * pi} == -1)
strwidth(sumex)
strheight(sumex)
par(op) # reset to previous setting

sunflowerplot  Produce a Sunflower Scatter Plot

Description

Multiple points are plotted as ‘sunflowers’ with multiple leaves (‘petals’) such that overplotting is visualized instead of accidental and invisible.

Usage

sunflowerplot(x, ...)

# Default S3 method:
sunflowerplot(x, y = NULL, number, log = "", digits = 6,
xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
add = FALSE, rotate = FALSE,
pch = 16, cex = 0.8, cex.fact = 1.5,
col = par("col"), bg = NA, size = 1/8, seg.col = 2,
seg.lwd = 1.5, ...)

# S3 method for class 'formula'
sunflowerplot(formula, data = NULL, xlab = NULL, ylab = NULL, ...,
subset, na.action = NULL)

Arguments

x numeric vector of x-coordinates of length n, say, or another valid plotting structure, as for plot.default, see also xy.coords.
y numeric vector of y-coordinates of length n.
number integer vector of length n. number[i] = number of replicates for (x[i], y[i]), may be 0. Default (missing(number)): compute the exact multiplicity of the points x[, y[, via xyTable()].
log character indicating log coordinate scale, see plot.default.
digits when number is computed (i.e., not specified), x and y are rounded to digits significant digits before multiplicities are computed.
xlab, ylab character label for x-, or y-axis, respectively.
xlim, ylim numeric(2) limiting the extents of the x-, or y-axis.
add logical; should the plot be added on a previous one ? Default is FALSE.
rotate logical; if TRUE, randomly rotate the sunflowers (preventing artefacts).
pch plotting character to be used for points (number[i]==1) and center of sunflowers.
cex: numeric; character size expansion of center points (s. pch).

cex.fact: numeric shrinking factor to be used for the center points when there are flower leaves, i.e., cex / cex.fact is used for these.
col, bg: colors for the plot symbols, passed to plot.default.
size: of sunflower leaves in inches, 1[in] := 2.54[cm]. Default: 1/8", approximately 3.2mm.
seg.col: color to be used for the segments which make the sunflowers leaves, see par(col=); col = "gold" reminds of real sunflowers.
seg.lwd: numeric; the line width for the leaves’ segments.
... further arguments to plot [if add = FALSE], or to be passed to or from another method.
formula: a formula, such as y ~ x.
data: a data.frame (or list) from which the variables in formula should be taken.
subset: an optional vector specifying a subset of observations to be used in the fitting process.
na.action: a function which indicates what should happen when the data contain NAs. The default is to ignore case with missing values.

Details
This is a generic function with default and formula methods.

For number[i] == 1, a (slightly enlarged) usual plotting symbol (pch) is drawn. For number[i] > 1, a small plotting symbol is drawn and number[i] equi-angular ‘rays’ emanate from it.

If rotate = TRUE and number[i] >= 2, a random direction is chosen (instead of the y-axis) for the first ray. The goal is to jitter the orientations of the sunflowers in order to prevent artefactual visual impressions.

Value
A list with three components of same length,

x: x coordinates
y: y coordinates
number: number

Use xyTable() (from package grDevices) if you are only interested in this return value.

Side Effects
A scatter plot is drawn with ‘sunflowers’ as symbols.

symbols

Draw Symbols (Circles, Squares, Stars, Thermometers, Boxplots)

Description

This function draws symbols on a plot. One of six symbols; circles, squares, rectangles, stars, thermometers, and boxplots, can be plotted at a specified set of x and y coordinates. Specific aspects of the symbols, such as relative size, can be customized by additional parameters.

Usage

symbols(x, y = NULL, circles, squares, rectangles, stars, thermometers, boxplots, inches = TRUE, add = FALSE, fg = par("col"), bg = NA, xlab = NULL, ylab = NULL, main = NULL, xlim = NULL, ylim = NULL, ...)
Arguments

x, y  
the x and y co-ordinates for the centres of the symbols. They can be specified in any way which is accepted by `xy.coords`.

circles  
a vector giving the radii of the circles.

squares  
a vector giving the length of the sides of the squares.

rectangles  
a matrix with two columns. The first column gives widths and the second the heights of rectangles.

stars  
a matrix with three or more columns giving the lengths of the rays from the center of the stars. NA values are replaced by zeroes.

thermometers  
a matrix with three or four columns. The first two columns give the width and height of the thermometer symbols. If there are three columns, the third is taken as a proportion: the thermometers are filled (using colour fg) from their base to this proportion of their height. If there are four columns, the third and fourth columns are taken as proportions and the thermometers are filled between these two proportions of their heights. The part of the box not filled in fg will be filled in the background colour (default transparent) given by bg.

boxplots  
a matrix with five columns. The first two columns give the width and height of the boxes, the next two columns give the lengths of the lower and upper whiskers and the fifth the proportion (with a warning if not in [0,1]) of the way up the box that the median line is drawn.

inches  
TRUE, FALSE or a positive number. See ‘Details’.

add  
if add is TRUE, the symbols are added to an existing plot, otherwise a new plot is created.

fg  
colour(s) the symbols are drawn in.

bg  
if specified, the symbols are filled with colour(s), the vector bg being recycled to the number of symbols. The default is to leave the symbols unfilled.

xlab  
the x label of the plot if add is not true. Defaults to the `deparse`d expression used for x.

ylab  
the y label of the plot. Unused if add = TRUE.

main  
a main title for the plot. Unused if add = TRUE.

xlim  
numeric vector of length 2 giving the x limits for the plot. Unused if add = TRUE.

ylim  
numeric vector of length 2 giving the y limits for the plot. Unused if add = TRUE.

...  
graphics parameters can also be passed to this function, as can the plot aspect ratio `asp` (see `plot.window`).

Details

Observations which have missing coordinates or missing size parameters are not plotted. The exception to this is `stars`. In that case, the length of any ray which is NA is reset to zero.

Argument `inches` controls the sizes of the symbols. If TRUE (the default), the symbols are scaled so that the largest dimension of any symbol is one inch. If a positive number is given the symbols are scaled to make largest dimension this size in inches (so TRUE and 1 are equivalent). If `inches` is FALSE, the units are taken to be those of the appropriate axes. (For circles, squares and stars the units of the x axis are used. For boxplots, the lengths of the whiskers are regarded as dimensions alongside width and height when scaling by `inches`, and are otherwise interpreted in the units of the y axis.)
Circles of radius zero are plotted at radius one pixel (which is device-dependent). Circles of a very small non-zero radius may or may not be visible, and may be smaller than circles of radius zero. On Windows devices circles are plotted at radius at least one pixel as some Windows versions omit smaller circles.

References

See Also

`stars` for drawing stars with a bit more flexibility.

If you are thinking about doing ‘bubble plots’ by `symbols(*, circles=*)`, you should really consider using `sunflowerplot` instead.

Examples

```r
require(stats); require(grDevices)
x <- 1:10
y <- sort(10*runif(10))
z <- runif(10)
z3 <- cbind(z, 2*runif(10), runif(10))
symbols(x, y, thermometers = cbind(.5, 1, z), inches = .5, fg = 1:10)
symbols(x, y, thermometers = z3, inches = FALSE)
text(x, y, apply(format(round(z3, digits = 2)), 1, paste, collapse = " ", ),
adj = c(-.2,0), cex = .75, col = "purple", xpd = NA)

## Note that example(trees) shows more sensible plots!
N <- nrow(trees)
with(trees, {
  ## Girth is diameter in inches
  symbols(Height, Volume, circles = Girth/24, inches = FALSE,
    main = "Trees' Girth")  # xlab and ylab automatically
  ## Colours too:
  op <- palette(rainbow(N, end = 0.9))
symbols(Height, Volume, circles = Girth/16, inches = FALSE, bg = 1:N,
    fg = "gray30", main = "symbols(*, circles = Girth/16, bg = 1:N")
  palette(op)
})
```

Description

text draws the strings given in the vector labels at the coordinates given by x and y. y may be missing since `xy.coords(x, y)` is used for construction of the coordinates.
Usage

text(x, ...)

## Default S3 method:
text(x, y = NULL, labels = seq_along(x$x), adj = NULL,
pos = NULL, offset = 0.5, vfont = NULL,
cex = 1, col = NULL, font = NULL, ...)

Arguments

x, y numeric vectors of coordinates where the text labels should be written. If the length of x and y differs, the shorter one is recycled.

labels a character vector or expression specifying the text to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by as.character. If labels is longer than x and y, the coordinates are recycled to the length of labels.

adj one or two values in \([0, 1]\) which specify the x (and optionally y) adjustment of the labels. On most devices values outside that interval will also work.

pos a position specifier for the text. If specified this overrides any adj value given. Values of 1, 2, 3 and 4, respectively indicate positions below, to the left of, above and to the right of the specified coordinates.

offset when pos is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.

vfont NULL for the current font family, or a character vector of length 2 for Hershey vector fonts. The first element of the vector selects a typeface and the second element selects a style. Ignored if labels is an expression.

cex numeric character expansion factor; multiplied by \(\text{par}("cex")\) yields the final character size. NULL and NA are equivalent to 1.0.

col, font the color and (if vfont = NULL) font to be used, possibly vectors. These default to the values of the global graphical parameters in \(\text{par}()\).

... further graphical parameters (from \(\text{par}\)), such as srt, family and xpd.

Details

labels must be of type character or expression (or be coercible to such a type). In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc.

adj allows adjustment of the text with respect to \((x, y)\). Values of 0, 0.5, and 1 specify left/bottom, middle and right/top alignment, respectively. The default is for centered text, i.e., adj = c(0.5, NA). Accurate vertical centering needs character metric information on individual characters which is only available on some devices. Vertical alignment is done slightly differently for character strings and for expressions: adj = c(0,0) means to left-justify and to align on the baseline for strings but on the bottom of the bounding box for expressions. This also affects vertical centering: for strings the centering excludes any descenders whereas for expressions it includes them. Using NA for strings centers them, including descenders.

The pos and offset arguments can be used in conjunction with values returned by identify to recreate an interactively labelled plot.

Text can be rotated by using graphical parameters srt (see \(\text{par}\)); this rotates about the centre set by adj.
Graphical parameters col, cex and font can be vectors and will then be applied cyclically to the labels (and extra values will be ignored). NA values of font are replaced by par("font"), and similarly for col.

Labels whose x, y or labels value is NA are omitted from the plot.

What happens when font = 5 (the symbol font) is selected can be both device- and locale-dependent. Most often labels will be interpreted in the Adobe symbol encoding, so e.g. "d" is delta, and "\300" is aleph.

**Euro symbol**

The Euro symbol may not be available in older fonts. In current versions of Adobe symbol fonts it is character 160, so text(x, y, "\xA0", font = 5) may work. People using Western European locales on Unix-alikes can probably select ISO-8895-15 (Latin-9) which has the Euro as character 165: this can also be used for postscript and pdf. It is \u20ac in Unicode, which can be used in UTF-8 locales.

The Euro should be rendered correctly by X11 in UTF-8 locales, but the corresponding single-byte encoding in postscript and pdf will need to be selected as ISOLatin9.enc (and the font will need to contain the Euro glyph, which for example older printers may not).

**Plot Annotation**

**Description**

This function can be used to add labels to a plot. Its first four principal arguments can also be used as arguments in most high-level plotting functions. They must be of type character or expression. In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc: see plotmath

**Usage**

```r
title(main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
     line = NA, outer = FALSE, ...)
```

**Arguments**

- `main`: The main title (on top) using font, size (character expansion) and color `par(c("font.main", "cex.main", "col.main")).`
- `sub`: Sub-title (at bottom) using font, size and color `par(c("font.sub", "cex.sub", "col.sub")).`
- `xlab`: X axis label using font, size and color `par(c("font.lab", "cex.lab", "col.lab")).`
- `ylab`: Y axis label, same font attributes as `xlab``.
- `line`: specifying a value for line overrides the default placement of labels, and places them this many lines outwards from the plot edge.
- `outer`: a logical value. If TRUE, the titles are placed in the outer margins of the plot.
- `...`: further graphical parameters from `par`. Use e.g., `col.main` or `cex.sub` instead of just `col` or `cex`. `adj` controls the justification of the titles. `xpd` can be used to set the clipping region: this defaults to the figure region unless `outer = TRUE`, otherwise the device region and can only be increased. `mgp` controls the default placing of the axis titles.

**Details**

The labels passed to `title` can be character strings or language objects (names, calls or expressions), or a list containing the string to be plotted, and a selection of the optional modifying graphical parameters `cex=`, `col= and `font=`. Other objects will be coerced by `as.graphicsAnnot`.

The position of `main` defaults to being vertically centered in (outer) margin 3 and justified horizontally according to `par("adj")` on the plot region (device region for `outer = TRUE`).

The positions of `xlab`, `ylab` and `sub` are `line` (default for `xlab` and `ylab` being `par("mgp")[1]` and increased by 1 for `sub`) lines (of height `par("mex")`) into the appropriate margin, justified in the text direction according to `par("adj")` on the plot/device region.

Examples

plot(cars, main = "") # here, could use main directly
title(main = "Stopping Distance versus Speed")

plot(cars, main ="")
title(main = list("Stopping Distance versus Speed", cex = 1.5, col = "red", font = 3))

## Specifying "...":
plot(1, col.axis = "sky blue", col.lab = "thistle")
title("Main Title", sub = "sub title", cex.main = 2, font.main = 4, col.main = "blue", cex.sub = 0.75, font.sub = 3, col.sub = "red")

x <- seq(-4, 4, len = 101)
y <- cbind(sin(x), cos(x))
matplot(x, y, type = "l", xaxt = "n",
main = expression(paste(plain(sin) * phi, " and ", plain(cos) * phi)),
ylab = expression("sin" * phi, "cos" * phi), # only 1st is taken
xlab = expression(paste("Phase Angle ", phi)),
col.main = "blue")
axis(1, at = c(-pi, -pi/2, 0, pi/2, pi),
labels = expression(-pi, -pi/2, 0, pi/2, pi))
abline(h = 0, v = pi/2 * c(-1,1), lty = 2, lwd = .1, col = "gray70")

Description

xinch and yinch convert the specified number of inches given as their arguments into the correct units for plotting with graphics functions. Usually, this only makes sense when normal coordinates are used, i.e., no log scale (see the log argument to par).

xyinch does the same for a pair of numbers xy, simultaneously.

Usage

xinch(x = 1, warn.log = TRUE)
yinch(y = 1, warn.log = TRUE)
xyinch(xy = 1, warn.log = TRUE)

Arguments

x, y numeric vector
xy numeric of length 1 or 2.
warn.log logical; if TRUE, a warning is printed in case of active log scale.
Examples

```r
all(c(xinch(), yinch()) == xyinch()) # TRUE
xyinch()
xyinch # to see that is really delta("usr") / "pin"
```

## plot labels offset 0.12 inches to the right
## of plotted symbols in a plot
with(mtcars, {
  plot(mpg, disp, pch = 19, main = "Motor Trend Cars")
  text(mpg + xinch(0.12), disp, row.names(mtcars),
       adj = 0, cex = .7, col = "blue")
})

xspline

---

**xspline**

*Draw an X-spline*

---

**Description**

Draw an X-spline, a curve drawn relative to control points.

**Usage**

```r
xspline(x, y = NULL, shape = 0, open = TRUE, repEnds = TRUE,
draw = TRUE, border = par("fg"), col = NA, ...)
```

**Arguments**

- `x, y` vectors containing the coordinates of the vertices of the polygon. See `xy.coords` for alternatives.
- `shape` A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
- `open` A logical value indicating whether the spline is an open or a closed shape.
- `repEnds` For open X-splines, a logical value indicating whether the first and last control points should be replicated for drawing the curve. Ignored for closed X-splines.
- `draw` logical: should the X-spline be drawn? If false, a set of line segments to draw the curve is returned, and nothing is drawn.
- `border` the color to draw the curve. Use `border = NA` to omit borders.
- `col` the color for filling the shape. The default, `NA`, is to leave unfilled.
- `...` graphical parameters such as `lty`, `xpd`, `lend`, `ljoin` and `lmitre` can be given as arguments.

**Details**

An X-spline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline
interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1).
If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open X-splines, the start and end control points must have a shape of 0 (and non-zero values are
silently converted to zero).

For open X-splines, by default the start and end control points are replicated before the curve is
drawn. A curve is drawn between (interpolating or approximating) the second and third of each set
of four control points, so this default behaviour ensures that the resulting curve starts at the first
control point you have specified and ends at the last control point. The default behaviour can be
turned off via the repEnds argument.

Value

If draw = TRUE, NULL otherwise a list with elements x and y which could be passed to lines,
polygon and so on.
Invisible in both cases.

Note

Two-dimensional splines need to be created in an isotropic coordinate system. Device coordinates
are used (with an anisotropy correction if needed.)

absolute.size

References

---

Absolute Size of a Grob

Description

This function converts a unit object into absolute units. Absolute units are unaffected, but non-absolute units are converted into "null" units.

Usage

absolute.size(unit)

Arguments

unit An object of class "unit".

Details

Absolute units are things like "inches", "cm", and "lines". Non-absolute units are "npc" and "native".

This function is designed to be used in widthDetails and heightDetails methods.

Value

An object of class "unit".

Author(s)

Paul Murrell

See Also

widthDetails and heightDetails methods.
arrow

Describe arrows to add to a line.

Description

Produces a description of what arrows to add to a line. The result can be passed to a function that draws a line, e.g., `grid.lines`.

Usage

```r
arrow(angle = 30, length = unit(0.25, "inches"),
      ends = "last", type = "open")
```

Arguments

- **angle**
  - The angle of the arrow head in degrees (smaller numbers produce narrower, pointier arrows). Essentially describes the width of the arrow head.
- **length**
  - A unit specifying the length of the arrow head (from tip to base).
- **ends**
  - One of "last", "first", or "both", indicating which ends of the line to draw arrow heads.
- **type**
  - One of "open" or "closed" indicating whether the arrow head should be a closed triangle.

Examples

```r
arrow()
```

calcStringMetric

Calculate Metric Information for Text

Description

This function returns the ascent, descent, and width metric information for a character or expression vector.

Usage

```r
calcStringMetric(text)
```

Arguments

- **text**
  - A character or expression vector.

Value

A list with three numeric components named ascent, descent, and width. All values are in inches.
**WARNING**

The metric information from this function is based on the font settings that are in effect when this function is called. It will not necessarily correspond to the metric information of any text that is drawn on the page.

**Author(s)**

Paul Murrell

**See Also**

`stringAscent`, `stringDescent`, `grobAscent`, and `grobDescent`.

**Examples**

```r
grid.newpage()
grid.segments(.01, .5, .99, .5, gp=gpar(col="grey"))
metrics <- calcStringMetric(letters)
grid.rect(x=1:26/27,
  width=unit(metrics$width, "inches"),
  height=unit(metrics$ascent, "inches"),
  just="bottom",
  gp=gpar(col="red"))
grid.rect(x=1:26/27,
  width=unit(metrics$width, "inches"),
  height=unit(metrics$descent, "inches"),
  just="top",
  gp=gpar(col="red"))
grid.text(letters, x=1:26/27, just="bottom")

test <- function(x) {
  grid.text(x, just="bottom")
  metric <- calcStringMetric(x)
  if (is.character(x)) {
    grid.rect(width=unit(metric$width, "inches"),
              height=unit(metric$ascent, "inches"),
              just="bottom",
              gp=gpar(col=rgb(1,0,0,.5)))
    grid.rect(width=unit(metric$width, "inches"),
              height=unit(metric$descent, "inches"),
              just="top",
              gp=gpar(col=rgb(1,0,0,.5)))
  } else {
    grid.rect(width=unit(metric$width, "inches"),
              y=unit(.5, "npc") + unit(metric[2], "inches"),
              height=unit(metric$ascent, "inches"),
              just="bottom",
              gp=gpar(col=rgb(1,0,0,.5)))
    grid.rect(width=unit(metric$width, "inches"),
              height=unit(metric$descent, "inches"),
              just="bottom",
              gp=gpar(col=rgb(1,0,0,.5)))
  }
}

tests <- list("t",
```
Create a Viewport with Scales based on Data

Description

This is a convenience function for producing a viewport with x- and/or y-scales based on numeric values passed to the function.

Usage

dataViewport(xData = NULL, yData = NULL, xscale = NULL, yscale = NULL, extension = 0.05, ...)

Arguments

- **xData**: A numeric vector of data.
- **yData**: A numeric vector of data.
- **xscale**: A numeric vector (length 2).
- **yscale**: A numeric vector (length 2).
- **extension**: A numeric. If length greater than 1, then first value is used to extend the xscale and second value is used to extend the yscale.
- **...**: All other arguments will be passed to a call to the `viewport()` function.

Details

If `xscale` is not specified then the values in `x` are used to generate an x-scale based on the range of `x`, extended by the proportion specified in `extension`. Similarly for the y-scale.

Value

A grid viewport object.
**depth**

*depth*

Determine the number of levels in an object.

**Description**

Determine the number of levels in a viewport stack or tree, in a viewport path, or in a grob path.

**Usage**

```r
depth(x, ...)  
## S3 method for class 'viewport'
depth(x, ...)  
## S3 method for class 'path'
depth(x, ...)
```

**Arguments**

- `x` Typically a viewport or viewport stack or viewport tree or viewport list, or a viewport path, or a grob path.
- `...` Arguments used by other methods.

**Details**

Depths of paths are pretty straightforward because they contain no branchings. The depth of a viewport stack is the sum of the depths of the components of the stack. The depth of a viewport tree is the depth of the parent plus the depth of the children. The depth of a viewport list is the depth of the last component of the list.

**Value**

An integer value.

**See Also**

`viewport`, `vpPath`, `gPath`.

**Examples**

```r
vp <- viewport()
depth(vp)
depth(vpStack(vp, vp))
depth(vpList(vpStack(vp, vp), vp))
depth(vpPath("vp"))
depth(vpPath("vp1", "vp2"))
```
**drawDetails**  

### Customising grid Drawing

**Description**
These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing of a new class derived from grob (or gTree).

**Usage**
```
drawDetails(x, recording)
predrawDetails(x)
postDrawDetails(x)
```

**Arguments**
- `x`  
  A grid grob.
- `recording`  
  A logical value indicating whether a grob is being added to the display list or redrawn from the display list.

**Details**
These functions are called by the `grid.draw` methods for grobs and gTrees.

`predrawDetails` is called first during the drawing of a grob. This is where any additional viewports should be pushed (see, for example, `grid:::predrawDetails.frame`). Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push and up any viewports in the `childrenvp` slot so there is typically nothing to do here.

`drawDetails` is called next and is where any additional calculations and graphical output should occur (see, for example, `grid:::drawDetails.xaxis`). Note that the default behaviour for gTrees is to draw all grobs in the `children` slot so there is typically nothing to do here.

`postDrawDetails` is called last and should reverse anything done in `predrawDetails` (i.e., pop or up any viewports that were pushed; again, see, for example, `grid:::postDrawDetails.frame`). Note that the default behaviour for grobs is to pop any viewports that were pushed so there is typically nothing to do here.

Note that `predrawDetails` and `postDrawDetails` are also called in the calculation of "grobwidth" and "grobheight" units.

**Value**
None of these functions are expected to return a value.

**Author(s)**
Paul Murrell

**See Also**
`grid.draw`
**editDetails**

*Customising grid Editing*

**Description**

This generic hook function is called whenever a grid grob is edited via `grid.edit` or `editGrob`. This provides an opportunity for customising the editing of a new class derived from grob (or `gTree`).

**Usage**

`editDetails(x, specs)`

**Arguments**

- `x`: A grid grob.
- `specs`: A list of named elements. The names indicate the grob slots to modify and the values are the new values for the slots.

**Details**

This function is called by `grid.edit` and `editGrob`. A method should be written for classes derived from grob or `gTree` if a change in a slot has an effect on other slots in the grob or children of a `gTree` (e.g., see `grid:::editDetails.xaxis`).

Note that the slot already has the new value.

**Value**

The function MUST return the modified grob.

**Author(s)**

Paul Murrell

**See Also**

`grid.edit`
Usage

```r
explode(x)
```  
## S3 method for class 'character'
```r
explode(x)
```  
## S3 method for class 'path'
```r
explode(x)
```  
Arguments

- `x`: Typically a viewport path or a grob path, but a character vector containing zero or more path separators may also be given.

Value

A character vector.

See Also

`vpPath`, `gPath`.

Examples

```r
explode("vp1::vp2")
explode(vpPath("vp1", "vp2"))
```

---

**gEdit**

Create and Apply Edit Objects

Description

The functions `gEdit` and `gEditList` create objects representing an edit operation (essentially a list of arguments to `editGrob`).

The functions `applyEdit` and `applyEdits` apply one or more edit operations to a graphical object.

These functions are most useful for developers creating new graphical functions and objects.

Usage

```r
gEdit(...)
gEditList(...)
applyEdit(x, edit)
applyEdits(x, edits)
```

Arguments

- `...`: one or more arguments to the `editGrob` function (for `gEdit`) or one or more "gEdit" objects (for `gEditList`).
- `x`: a grob (grid graphical object).
- `edit`: a "gEdit" object.
- `edits`: either a "gEdit" object or a "gEditList" object.
getNames

Value

getNames returns an object of class "gEdit".
gEditList returns an object of class "gEditList".
applyEdit and applyEditList return the modified grob.

Author(s)

Paul Murrell

See Also

grob editGrob

Examples

grid.rect(gp=gpar(col="red"))
# same thing, but more verbose
grid.draw(applyEdit(rectGrob(), gEdit(gp=gpar(col="red"))))

getNames

List the names of grobs on the display list

Description

Returns a character vector containing the names of all top-level grobs on the display list.

Usage

getNames()

Value

A character vector.

Author(s)

Paul Murrell

Examples

grid.grill()
getNames()
Handling Grid Graphical Parameters

gpar() should be used to create a set of graphical parameter settings. It returns an object of class "gpar". This is basically a list of name-value pairs.
get.gpar() can be used to query the current graphical parameter settings.

Usage

\begin{verbatim}
gpar(...)  
get.gpar(names = NULL)
\end{verbatim}

Arguments

\begin{verbatim}
... Any number of named arguments.
names A character vector of valid graphical parameter names.
\end{verbatim}

Details

All grid viewports and (predefined) graphical objects have a slot called gp, which contains a "gpar" object. When a viewport is pushed onto the viewport stack and when a graphical object is drawn, the settings in the "gpar" object are enforced. In this way, the graphical output is modified by the gp settings until the graphical object has finished drawing, or until the viewport is popped off the viewport stack, or until some other viewport or graphical object is pushed or begins drawing.

The default parameter settings are defined by the ROOT viewport, which takes its settings from the graphics device. These defaults may differ between devices (e.g., the default fill setting is different for a PNG device compared to a PDF device).

Valid parameter names are:

\begin{verbatim}
col Colour for lines and borders.
fill Colour for filling rectangles, polygons, ...
alpha Alpha channel for transparency
lty Line type
lwd Line width
lex Multiplier applied to line width
lineend Line end style (round, butt, square)
linejoin Line join style (round, mitre, bevel)
linemitre Line mitre limit (number greater than 1)
fontsize The size of text (in points)
cex Multiplier applied to fontsize
fontfamily The font family
fontface The font face (bold, italic, ...)
lineheight The height of a line as a multiple of the size of text
font Font face (alias for fontface; for backward compatibility)
\end{verbatim}

For more details of many of these, see the help for the corresponding graphical parameter par in base graphics. (This may have a slightly different name, e.g. lend, ljoin, lmitre, family.)
Colours can be specified in one of the forms returned by `rgb`, as a name (see `colors`) or as a non-negative integer index into the current palette (with zero being taken as transparent). (Negative integer values are now an error.)

The alpha setting is combined with the alpha channel for individual colours by multiplying (with both alpha settings normalised to the range 0 to 1).

The size of text is `fontsize * cex`. The size of a line is `fontsize * cex * lineheight`.

The `cex` setting is cumulative; if a viewport is pushed with a `cex` of 0.5 then another viewport is pushed with a `cex` of 0.5, the effective `cex` is 0.25.

The `alpha` and `cex` settings are also cumulative.

Changes to the `fontfamily` may be ignored by some devices, but is supported by PostScript, PDF, X11, Windows, and Quartz. The `fontfamily` may be used to specify one of the Hershey Font families (e.g., `HersheySerif`) and this specification will be honoured on all devices.

The specification of `fontface` can be an integer or a string. If an integer, then it follows the R base graphics standard: 1 = plain, 2 = bold, 3 = italic, 4 = bold italic. If a string, then valid values are: "plain", "bold", "italic", "oblique", and "bold.italic". For the special case of the HersheySerif font family, "cyrillic", "cyrillic.oblique", and "EUC" are also available.

All parameter values can be vectors of multiple values. (This will not always make sense – for example, viewports will only take notice of the first parameter value.)

`get.gpar()` returns all current graphical parameter settings.

### Value
An object of class "gpar".

### Author(s)
Paul Murrell

### See Also
`Hershey`.

### Examples
```r
gp <- get.gpar()
utils::str(gp)
## These *do* nothing but produce a "gpar" object:
gpar(col = "red")
gpar(col = "blue", lty = "solid", lwd = 3, fontsize = 16)
get.gpar(c("col", "lty"))
grid.newpage()
vp <- viewport(w = .8, h = .8, gp = gpar(col="blue"))
grid.draw(gTree(children=gList(rectGrob(gp = gpar(col="red")),
   textGrob(paste("The rect is its own colour (red)",
   "but this text is the colour",
   "set by the gTree (green)",
   sep = "\n")),
   gp = gpar(col="green"), vp = vp))
grid.text("This text is the colour set by the viewport (blue),
   y = 1, just = c("center", "bottom"),
   gp = gpar(fontsize=20), vp = vp)
grid.newpage()
```
## example with multiple values for a parameter
pushViewport(viewport())
grid.points(1:10/11, 1:10/11, gp = gpar(col=1:10))
popViewport()

---

### gPath

**Concatenate Grob Names**

**Description**

This function can be used to generate a grob path for use in `grid.edit` and friends.

A grob path is a list of nested grob names.

**Usage**

```
gPath(...)  
```

**Arguments**

```
...  
```

**Character values which are grob names.**

**Details**

Grob names must only be unique amongst grobs which share the same parent in a gTree.

This function can be used to generate a specification for a grob that includes the grob’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

**Value**

A `gPath` object.

**See Also**

`grob`, `editGrob`, `addGrob`, `removeGrob`, `getGrob`, `setGrob`

**Examples**

```
gPath("g1", "g2")
```
Grid Viewports

Description

General information about the grid graphics package.

Details

Grid graphics provides an alternative to the standard R graphics. The user is able to define arbitrary rectangular regions (called viewports) on the graphics device and define a number of coordinate systems for each region. Drawing can be specified to occur in any viewport using any of the available coordinate systems.

Grid graphics and standard R graphics do not mix!

Type `library(help = grid)` to see a list of (public) Grid graphics functions.

## Diagram of a simple layout
grid.show.layout(grid.layout(4, 2, 
    heights=unit(rep(1, 4),
               c("lines", "lines", "lines", "null")),
    widths=unit(c(1, 1), "inches")))
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6, 
                        w=unit(1, "inches"), h=unit(1, "inches")))
## A flash plotting example
grid.multipanel(vp=viewport(0.5, 0.5, 0.8, 0.8))
```
**Grid Viewports**

**Usage**

```r
viewport(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
       width = unit(1, "npc"), height = unit(1, "npc"),
       default.units = "npc", just = "centre",
       gp = gpar(), clip = "inherit",
       xscale = c(0, 1), yscale = c(0, 1),
       angle = 0,
       layout = NULL,
       layout.pos.row = NULL, layout.pos.col = NULL,
       name = NULL)
vpList(...) vpStack(...) vpTree(parent, children)
```

**Arguments**

- **x** A numeric vector or unit object specifying x-location.
- **y** A numeric vector or unit object specifying y-location.
- **width** A numeric vector or unit object specifying width.
- **height** A numeric vector or unit object specifying height.
- **default.units** A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- **just** A string or numeric vector specifying the justification of the viewport relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
- **gp** An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **clip** One of "on", "inherit", or "off", indicating whether to clip to the extent of this viewport, inherit the clipping region from the parent viewport, or turn clipping off altogether. For back-compatibility, a logical value of TRUE corresponds to "on" and FALSE corresponds to "inherit".
- **xscale** A numeric vector of length two indicating the minimum and maximum on the x-scale. The limits may not be identical.
- **yscale** A numeric vector of length two indicating the minimum and maximum on the y-scale. The limits may not be identical.
- **angle** A numeric value indicating the angle of rotation of the viewport. Positive values indicate the amount of rotation, in degrees, anticlockwise from the positive x-axis.
- **layout** A Grid layout object which splits the viewport into subregions.
- **layout.pos.row** A numeric vector giving the rows occupied by this viewport in its parent’s layout.
- **layout.pos.col** A numeric vector giving the columns occupied by this viewport in its parent’s layout.
- **name** A character value to uniquely identify the viewport once it has been pushed onto the viewport tree.
- **...** Any number of grid viewport objects.
parent A grid viewport object.

children A vpList object.

Details

The location and size of a viewport are relative to the coordinate systems defined by the viewport’s parent (either a graphical device or another viewport). The location and size can be specified in a very flexible way by specifying them with unit objects. When specifying the location of a viewport, specifying both \texttt{layout.pos.row} and \texttt{layout.pos.col} as \texttt{NULL} indicates that the viewport ignores its parent’s layout and specifies its own location and size (via its \texttt{locn}). If only one of \texttt{layout.pos.row} and \texttt{layout.pos.col} is \texttt{NULL}, this means occupy ALL of the appropriate row(s)/column(s). For example, \texttt{layout.pos.row = 1} and \texttt{layout.pos.col = NULL} means occupy all of row 1. Specifying non-\texttt{NULL} values for both \texttt{layout.pos.row} and \texttt{layout.pos.col} means occupy the intersection of the appropriate rows and columns. If a vector of length two is specified for \texttt{layout.pos.row} or \texttt{layout.pos.col}, this indicates a range of rows or columns to occupy. For example, \texttt{layout.pos.row = c(1, 3)} and \texttt{layout.pos.col = c(2, 4)} means occupy cells in the intersection of rows 1, 2, and 3, and columns, 2, 3, and 4.

Clipping obeys only the most recent viewport clip setting. For example, if you clip to viewport1, then clip to viewport2, the clipping region is determined wholly by viewport2, the size and shape of viewport1 is irrelevant (until viewport2 is popped of course).

If a viewport is rotated (because of its own \texttt{angle} setting or because it is within another viewport which is rotated) then the \texttt{clip} flag is ignored.

Viewport names need not be unique. When pushed, viewports sharing the same parent must have unique names, which means that if you push a viewport with the same name as an existing viewport, the existing viewport will be replaced in the viewport tree. A viewport name can be any string, but grid uses the reserved name \texttt{"ROOT"} for the top-level viewport. Also, when specifying a viewport name in \texttt{downViewport} and \texttt{seekViewport}, it is possible to provide a viewport path, which consists of several names concatenated using the separator (currently ::). Consequently, it is not advisable to use this separator in viewport names.

The viewports in a \texttt{vpList} are pushed in parallel. The viewports in a \texttt{vpStack} are pushed in series. When a \texttt{vpTree} is pushed, the parent is pushed first, then the children are pushed in parallel.

Value

An R object of class \texttt{viewport}.

        x=unit(1, "mm"), y=unit(1, "npc") - unit(1, "mm"),  
        just=c("left", "top"),  
        gp=gpar(fontsize=8))
}
```

```
grid.add  Add a Grid Graphical Object
```
Description

Add a grob to a gTree or a descendant of a gTree.

Usage

grid.add(gPath, child, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE, redraw = TRUE)

addGrob(gTree, child, gPath = NULL, strict = FALSE, grep = FALSE, global = FALSE, warn = TRUE)

setChildren(x, children)

Arguments

gTree, x A gTree object.
gPath A gPath object. For grid.add this specifies a gTree on the display list. For addGrob this specifies a descendant of the specified gTree.
child A grob object.
children A gList object.
strict A boolean indicating whether the gPath must be matched exactly.
grep A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
warn A logical to indicate whether failing to find the specified gPath should trigger an error.
allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
redraw A logical value to indicate whether to redraw the grob.

Details

addGrob copies the specified grob and returns a modified grob.
grid.add destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.
setChildren is a basic function for setting all children of a gTree at once (instead of repeated calls to addGrob).

Value

addGrob returns a grob object; grid.add returns NULL.

Author(s)

Paul Murrell
grid.bezier

Draw a Bezier Curve

Description

These functions create and draw Bezier Curves (a curve drawn relative to 4 control points).

Usage

grid.bezier(...)

bezierGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),
    id = NULL, id.lengths = NULL,
    default.units = "npc", arrow = NULL,
    name = NULL, gp = gpar(), vp = NULL)

Arguments

x
A numeric vector or unit object specifying x-locations of spline control points.
y
A numeric vector or unit object specifying y-locations of spline control points.
id
A numeric vector used to separate locations in x and y into multiple beziers. All locations with the same id belong to the same bezier.
id.lengths
A numeric vector used to separate locations in x and y into multiple beziers. Specifies consecutive blocks of locations which make up separate beziers.
default.units
A string indicating the default units to use if x or y are only given as numeric vectors.
arrow
A list describing arrow heads to place at either end of the bezier, as produced by the arrow function.
nname
A character identifier.
gp
An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp
A Grid viewport object (or NULL).
... Arguments to be passed to bezierGrob.

Details

Both functions create a beziergrob (a graphical object describing a Bezier curve), but only grid.bezier draws the Bezier curve.

A Bezier curve is a line drawn relative to 4 control points.

Missing values are not allowed for x and y (i.e., it is not valid for a control point to be missing).

The curve is currently drawn using an approximation based on X-splines.

Value

A grob object.

See Also

grob, getGrob, addGrob, removeGrob.
grid.cap

See Also

Grid, viewport, arrow.
grid.xspline.

Examples

```r
x <- c(0.2, 0.2, 0.4, 0.4)
y <- c(0.2, 0.4, 0.4, 0.2)

grid.newpage()
grid.bezier(x, y)
grid.bezier(c(x, x + .4), c(y + .4, y + .4),
id=rep(1:2, each=4))
grid.segments(.4, .6, .6, .6)
grid.bezier(x, y,
  gp=gpar(lwd=3, fill="black"),
  arrow=arrow(type="closed"),
  vp=viewport(x=.9))
```

grid.cap  

Capture a raster image

Description

Capture the current contents of a graphics device as a raster (bitmap) image.

Usage

```r
grid.cap()
```

Details

This function is only implemented for on-screen graphics devices.

Value

A matrix of R colour names, or NULL if not available.

Author(s)

Paul Murrell

See Also

grid.raster
dev.capabilities to see if it is supported.
## grid.circle

*Draw a Circle*

## Examples

```r
dev.new(width=0.5, height=0.5)
grid.rect()
grid.text("hi")
cap <- grid.cap()
dev.off()

if(!is.null(cap))
  grid.raster(cap, width=0.5, height=0.5, interpolate=FALSE)
```

## Description

Functions to create and draw a circle.

## Usage

```r
grid.circle(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
gp=gpar(), draw=TRUE, vp=NULL)
circleGrob(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
gp=gpar(), vp=NULL)
```

## Arguments

- `x`: A numeric vector or unit object specifying x-locations.
- `y`: A numeric vector or unit object specifying y-locations.
- `r`: A numeric vector or unit object specifying radii.
- `default.units`: A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
- `name`: A character identifier.
- `gp`: An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- `draw`: A logical value indicating whether graphics output should be produced.
- `vp`: A Grid viewport object (or NULL).

## Details

Both functions create a circle grob (a graphical object describing a circle), but only `grid.circle()` draws the circle (and then only if `draw` is `TRUE`).

The radius may be given in any units; if the units are relative (e.g., "npc" or "native") then the radius will be different depending on whether it is interpreted as a width or as a height. In such cases, the smaller of these two values will be the result. To see the effect, type `grid.circle()` and adjust the size of the window.

What happens for very small radii is device-dependent: the circle may become invisible or be shown at a fixed minimum size. Circles of zero radius will not be plotted.
Value
A circle grob, grid.circle() returns the value invisibly.

Warning
Negative values for the radius are silently converted to their absolute value.

Grid, viewport

grid.clip
Set the Clipping Region

Description
These functions set the clipping region within the current viewport without altering the current coordinate system.

Usage
grid.clip(...)  
clipGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),  
width = unit(1, "npc"), height = unit(1, "npc"),  
just = "centre", hjust = NULL, vjust = NULL,  
default.units = "npc", name = NULL, vp = NULL)

Arguments
x A numeric vector or unit object specifying x-location.
y A numeric vector or unit object specifying y-location.
width A numeric vector or unit object specifying width.
height A numeric vector or unit object specifying height.
just The justification of the clip rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
hjust A numeric vector specifying horizontal justification. If specified, overrides the just setting.
vjust A numeric vector specifying vertical justification. If specified, overrides the just setting.
default.units A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name A character identifier.
vp A Grid viewport object (or NULL).
... Arguments passed to clipGrob.
Both functions create a clip rectangle (a graphical object describing a clip rectangle), but only `grid.clip` enforces the clipping.

Pushing or popping a viewport _always_ overrides the clip region set by a clip grob, regardless of whether that viewport explicitly enforces a clipping region.

**Value**

clipGrob returns a clip grob.

**Author(s)**

Paul Murrell

**See Also**

Grid, viewport

**Examples**

```r
# draw across entire viewport, but clipped
grid.clip(x = 0.3, width = 0.1)
grid.lines(gp=gpar(col="green", lwd=5))
# draw across entire viewport, but clipped (in different place)
grid.clip(x = 0.7, width = 0.1)
grid.lines(gp=gpar(col="red", lwd=5))
# Viewport sets new clip region
pushViewport(viewport(width=0.5, height=0.5, clip=TRUE))
grid.lines(gp=gpar(col="grey", lwd=3))
# Return to original viewport; get
# clip region from previous grid.clip()
# (NOT from previous viewport clip region)
popViewport()
grid.lines(gp=gpar(col="black"))
```

**grid.convert**

Convert Between Different grid Coordinate Systems

**Description**

These functions take a unit object and convert it to an equivalent unit object in a different coordinate system.

**Usage**

```r
convertX(x, unitTo, valueOnly = FALSE)
convertY(x, unitTo, valueOnly = FALSE)
convertWidth(x, unitTo, valueOnly = FALSE)
convertHeight(x, unitTo, valueOnly = FALSE)
convertUnit(x, unitTo,
             axisFrom = "x", typeFrom = "location",
             axisTo = axisFrom, typeTo = typeFrom,
             valueOnly = FALSE)
```
Arguments

- **x**: A unit object.
- **unitTo**: The coordinate system to convert the unit to. See the `unit` function for valid coordinate systems.
- **axisFrom**: Either "x" or "y" to indicate whether the unit object represents a value in the x- or y-direction.
- **typeFrom**: Either "location" or "dimension" to indicate whether the unit object represents a location or a length.
- **axisTo**: Same as **axisFrom**, but applies to the unit object that is to be created.
- **typeTo**: Same as **typeFrom**, but applies to the unit object that is to be created.
- **valueOnly**: A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.

Details

The `convertUnit` function allows for general-purpose conversions. The other four functions are just more convenient front-ends to it for the most common conversions.

The conversions occur within the current viewport.

It is not currently possible to convert to all valid coordinate systems (e.g., "strwidth" or "grob-width"). I’m not sure if all of these are impossible, they just seem implausible at this stage.

In normal usage of grid, these functions should not be necessary. If you want to express a location or dimension in inches rather than user coordinates then you should simply do something like `unit(1, "inches")` rather than something like `unit(0.134, "native")`.

In some cases, however, it is necessary for the user to perform calculations on a unit value and this function becomes necessary. In such cases, please take note of the warning below.

Value

A unit object in the specified coordinate system (unless **valueOnly** is TRUE in which case the returned value is a numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid. For example, suppose that I create a unit object as follows:

```
oneinch <- convertUnit(unit(1, "inches"), "native")
```

Now if I resize the device, the unit object in `oneinch` no longer corresponds to a physical length of 1 inch.

- `unit`
Examples

## A tautology
```
convertX(unit(1, "inches"), "inches")
```

## The physical units
```
convertX(unit(2.54, "cm"), "inches")
convertX(unit(25.4, "mm"), "inches")
convertX(unit(72.27, "points"), "inches")
convertX(unit(1/12*72.27, "picas"), "inches")
convertX(unit(72, "bigpts"), "inches")
convertX(unit(1157/1238*72.27, "dida"), "inches")
convertX(unit(1/12*1157/1238*72.27, "cicero"), "inches")
convertX(unit(65536*72.27, "scaledpts"), "inches")
convertX(unit(1/2.54, "inches"), "cm")
convertX(unit(1/25.4, "inches"), "mm")
```

## Location versus dimension
```
convertY(unit(2, "native"), "inches")
convertHeight(unit(2, "native"), "inches")
```

## From "x" to "y" (the conversion is via "inches")
```
convertUnit(unit(1, "native"), "native", axisFrom="x", axisTo="y")
```

## Convert several values at once
```
convertX(unit(c(0.5, 2.54), c("npc", "cm")), c("inches", "native"))
```

popViewport()

## Convert a complex unit
```
convertX(unit(1, "strwidth", "Hello"), "native")
```

---

grid.copy

Make a Copy of a Grid Graphical Object

Description

This function is redundant and will disappear in future versions.

Usage

```
grid.copy(grob)
```

Arguments

```
grob A grob object.
```
Value

A copy of the grob object.

Author(s)

Paul Murrell

See Also

grid.grob.

gird.curve  Draw a Curve Between Locations

Description

These functions create and draw a curve from one location to another.

Usage

grid.curve(...)
curveGrob(x1, y1, x2, y2, default.units = "npc",
curvature = 1, angle = 90, ncp = 1, shape = 0.5,
square = TRUE, squareShape = 1,
inflect = FALSE, arrow = NULL, open = TRUE,
depug = FALSE,
name = NULL, gp = gpar(), vp = NULL)
arcCurvature(theta)

Arguments

x1  A numeric vector or unit object specifying the x-location of the start point.
y1  A numeric vector or unit object specifying the y-location of the start point.
x2  A numeric vector or unit object specifying the x-location of the end point.
y2  A numeric vector or unit object specifying the y-location of the end point.
default.units A string indicating the default units to use if x1, y1, x2 or y2 are only given as numeric values.
curvature  A numeric value giving the amount of curvature. Negative values produce left-hand curves, positive values produce right-hand curves, and zero produces a straight line.
age  A numeric value between 0 and 180, giving an amount to skew the control points of the curve. Values less than 90 skew the curve towards the start point and values greater than 90 skew the curve towards the end point.
ccp  The number of control points used to draw the curve. More control points creates a smoother curve.
shape  A numeric vector of values between -1 and 1, which control the shape of the curve relative to its control points. See grid.xspline for more details.
grid.curve

square  A logical value that controls whether control points for the curve are created city-block fashion or obliquely. When ncp is 1 and angle is 90, this is typically TRUE, otherwise this should probably be set to FALSE (see Examples below).

squareShape  A shape value to control the behaviour of the curve relative to any additional control point that is inserted if square is TRUE.

inflect  A logical value specifying whether the curve should be cut in half and inverted (see Examples below).

arrow  A list describing arrow heads to place at either end of the curve, as produced by the arrow function.

open  A logical value indicating whether to close the curve (connect the start and end points).

debug  A logical value indicating whether debugging information should be drawn.

name  A character identifier.

gp  An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

vp  A Grid viewport object (or NULL).

Arguments to be passed to curveGrob.

theta  An angle (in degrees).

Details

Both functions create a curve grob (a graphical object describing an curve), but only grid.curve draws the curve.

The arcCurvature function can be used to calculate a curvature such that control points are generated on an arc corresponding to angle theta. This is typically used in conjunction with a large ncp to produce a curve corresponding to the desired arc.

Value

A grob object.

See Also

Grid, viewport, grid.xspline, arrow

Examples

curveTest <- function(i, j, ...) {
  pushViewport(viewport(layout.pos.col=j, layout.pos.row=i))
  do.call("grid.curve", c(list(x1=.25, y1=.25, x2=.75, y2=.75), list(...)))
  grid.text(sub("[^\)(]+\([^\)(]+\)\([^\)(]+\)\([^\)(]+\)"), "\1",
            deparse(substitute(list(...)))),
            y=unit(1, "npc"))
  popViewport()
}
# grid.newpage()
pushViewport(plotViewport(c(0, 0, 1, 0),
                          layout=grid.layout(2, 1, heights=c(2, 1))))
pushViewport(viewport(layout.pos.row=1,
                        layout=grid.layout(3, 3, respect=TRUE)))
curveTest(1, 1)
grid.delay

Encapsulate calculations and generating a grob

Description
Evaluates an expression that includes both calculations and generating a grob that depends on the calculations so that both the calculations and the grob generation will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.

Usage

delayGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.delay(expr, list, name=NULL, gp=NULL, vp=NULL)

Arguments

- **expr**: object of mode `expression` or call or an unevaluated expression.
- **list**: a list defining the environment in which `expr` is to be evaluated.
- **name**: A character identifier.
- **gp**: An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).

Details
A grob is created of special class "delayedgrob" (and drawn, in the case of `grid.delay`). The `makeContent` method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).
The `expr` argument should return a grob as its result. These functions are analogues of the `grid.record()` and `recordGrob()` functions; the difference is that these functions are based on the `makeContent()` hook, while those functions are based on the `drawDetails()` hook.

**Note**

This function must be used instead of the function `recordGraphics`; all of the dire warnings about using `recordGraphics` responsibly also apply here.

**Author(s)**

Paul Murrell

**See Also**

`recordGraphics`

**Examples**

```r
grid.delay({
  w <- convertWidth(unit(1, "inches"), "npc")
  rectGrob(width=w)
},
list())
```

---

### `grid.display.list` Control the Grid Display List

**Description**

Turn the Grid display list on or off.

**Usage**

```r
grid.display.list(on=TRUE)
engine.display.list(on=TRUE)
```

**Arguments**

- `on` A logical value to indicate whether the display list should be on or off.

**Details**

All drawing and viewport-setting operations are (by default) recorded in the Grid display list. This allows redrawing to occur following an editing operation. This display list could get very large so it may be useful to turn it off in some cases; this will of course disable redrawing.

All graphics output is also recorded on the main display list of the R graphics engine (by default). This supports redrawing following a device resize and allows copying between devices. Turning off this display list means that grid will redraw from its own display list for device resizes and copies. This will be slower than using the graphics engine display list.
Value
None.

WARNING
Turning the display list on causes the display list to be erased!
Turning off both the grid display list and the graphics engine display list will result in no redrawing whatsoever.

grid.DLapply Modify the Grid Display List

Description
Call a function on each element of the current display list.

Usage
grid.DLapply(FUN, ...)

Arguments
FUN A function; the first argument to this function is passed each element of the display list.
... Further arguments to pass to FUN.

Details
This function is insanely dangerous (for the grid display list).
Two token efforts are made to try to avoid ending up with complete garbage on the display list:

1. The display list is only replaced once all new elements have been generated (so an error during generation does not result in a half-finished display list).
2. All new elements must be either NULL or inherit from the class of the element that they are replacing.

Value
The side effect of these functions is usually to modify the grid display list.

See Also
Grid.
Examples

grid.newpage()
grid.rect(width=.4, height=.4, x=.25, y=.75, gp=gpar(fill="black"), name="r1")
grid.rect(width=.4, height=.4, x=.5, y=.5, gp=gpar(fill="grey"), name="r2")
grid.rect(width=.4, height=.4, x=.75, y=.25, gp=gpar(fill="white"), name="r3")
grid.DLapply(function(x) { if (is.grob(x)) x$gp <- gpar(); x })
grid.refresh()

Description

Produces graphical output from a graphical object.

Usage

grid.draw(x, recording=TRUE)

Arguments

x  
An object of class "grob" or NULL.

recording  
A logical value to indicate whether the drawing operation should be recorded on the Grid display list.

Details

This is a generic function with methods for grob and gTree objects.

The grob and gTree methods automatically push any viewports in a vp slot and automatically apply any gpar settings in a gp slot. In addition, the gTree method pushes and ups any viewports in a childrenvp slot and automatically calls grid.draw for any grobs in a children slot.

The methods for grob and gTree call the generic hook functions preDrawDetails, drawDetails, and postDrawDetails to allow classes derived from grob or gTree to perform additional viewport pushing/popping and produce additional output beyond the default behaviour for grobs and gTrees.

Value

None.

grob.
Examples

grid.newpage()
## Create a graphical object, but don’t draw it
l <- linesGrob()
## Draw it
grid.draw(l)

grid.edit

**Edit the Description of a Grid Graphical Object**

Description

Changes the value of one of the slots of a grob and redraws the grob.

Usage

grid.edit(gPath, ..., strict = FALSE, grep = FALSE,
          global = FALSE, allDevices = FALSE, redraw = TRUE)

grid.gedit(..., grep = TRUE, global = TRUE)

editGrob(grob, gPath = NULL, ..., strict = FALSE, grep = FALSE,
          global = FALSE, warn = TRUE)

Arguments

- `grob`: A grob object.
- `...`: Zero or more named arguments specifying new slot values.
- `gPath`: A gPath object. For `grid.edit` this specifies a grob on the display list. For `editGrob` this specifies a descendant of the specified grob.
- `strict`: A boolean indicating whether the gPath must be matched exactly.
- `grep`: A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
- `global`: A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
- `warn`: A logical to indicate whether failing to find the specified gPath should trigger an error.
- `allDevices`: A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
- `redraw`: A logical value to indicate whether to redraw the grob.

Details

`editGrob` copies the specified grob and returns a modified grob.

`grid.edit` destructively modifies a grob on the display list. If `redraw` is TRUE it then redraws everything to reflect the change.

Both functions call `editDetails` to allow a grob to perform custom actions and `validDetails` to check that the modified grob is still coherent.

`grid.gedit` (g for global) is just a convenience wrapper for `grid.edit` with different defaults.
grid.force

Value

editGrob returns a grob object; grid.edit returns NULL.

Author(s)

Paul Murrell

See Also

grob, getGrob, addGrob, removeGrob.

Examples

grid.newpage()
grid.xaxis(name = "xa", vp = viewport(width=.5, height=.5))
grid.edit("xa", gp = gpar(col="red"))
# won't work because no ticks (at is NULL)
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
grid.edit("xa", at = 1:4/5)
# Now it should work
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))

Description

Some grobs only generate their content to draw at drawing time; this function replaces such grobs with their at-drawing-time content.

Usage

grid.force(x, ...)
## Default S3 method:
grid.force(x, redraw = FALSE, ...)
## S3 method for class 'gPath'
grid.force(x, strict = FALSE, grep = FALSE, global = FALSE,
   redraw = FALSE, ...)
## S3 method for class 'grob'
grid.force(x, draw = FALSE, ...)
forceGrob(x)
grid.revert(x, ...)
## S3 method for class 'gPath'
grid.revert(x, strict = FALSE, grep = FALSE, global = FALSE,
   redraw = FALSE, ...)
## S3 method for class 'grob'
grid.revert(x, draw = FALSE, ...)

grid.force  Force a grob into its components
Arguments

x        For the default method, x should not be specified. Otherwise, x should be a grob or a gPath. If x is character, it is assumed to be a gPath.
strict   A boolean indicating whether the path must be matched exactly.
grep     Whether the path should be treated as a regular expression.
global   A boolean indicating whether the function should affect just the first match of the path, or whether all matches should be affected.
draw     logical value indicating whether a grob should be drawn after it is forced.
redraw   logical value indicating whether to redraw the grid scene after the forcing operation.
...      Further arguments for use by methods.

Details

Some grobs wait until drawing time to generate what content will actually be drawn (an axis, as produced by grid.xaxis(), with an at or NULL is a good example because it has to see what viewport it is going to be drawn in before it can decide what tick marks to draw).
The content of such grobs (e.g., the tick marks) are not usually visible to grid.ls() or accessible to grid.edit().
The grid.force() function replaces a grob with its at-drawing-time contents. For example, an axis will be replaced by a vanilla gTree with lines and text representing the axis tick marks that were actually drawn. This makes the tick marks visible to grid.ls() and accessible to grid.edit().
The forceGrob() function is the internal work horse for grid.force(), so will not normally be called directly by the user. It is exported so that methods can be written for custom grob classes if necessary.
The grid.revert() function reverses the effect of grid.force(), replacing forced content with the original grob.

Warning

Forcing an explicit grob produces a result as if the grob were drawn in the current drawing context. It may not make sense to draw the result in a different drawing context.

Note

These functions only have an effect for grobs that generate their content at drawing time using makeContext() and makeContent() methods (not for grobs that generate their content at drawing time using preDrawDetails() and drawDetails() methods).

Paul Murrell

Examples

grid.newpage()
pushViewport(viewport(width=.5, height=.5))
# Draw xaxis
grid.xaxis(name="xax")
grid.ls()
grid.frame  Create a Frame for Packing Objects

Description

These functions, together with grid.pack, grid.place, packGrob, and placeGrob are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with this function then use grid.pack or whatever to pack/place objects into the frame.

Usage

grid.frame(layout=NULL, name=NULL, gp=gpar(), vp=NULL, draw=TRUE)
frameGrob(layout=NULL, name=NULL, gp=gpar(), vp=NULL)

Arguments

layout A Grid layout, or NULL. This can be used to initialise the frame with a number of rows and columns, with initial widths and heights, etc.
name A character identifier.
v An object of class viewport, or NULL.
gp An object of class gpar; typically the output from a call to the function gpar.
draw Should the frame be drawn.

Details

Both functions create a frame grob (a graphical object describing a frame), but only grid.frame() draws the frame (and then only if draw is TRUE). Nothing will actually be drawn, but it will put the frame on the display list, which means that the output will be dynamically updated as objects are packed into the frame. Possibly useful for debugging.
Value
A frame grob. grid.frame() returns the value invisibly.

Author(s)
Paul Murrell

grid.pack

Examples
grid.newpage()
grid.frame(name="gf", draw=TRUE)
grid.pack("gf", rectGrob(gp=gpar(fill="grey")), width=unit(1, "null"))
grid.pack("gf", textGrob("hi there"), side="right")

---

grid.function  
**Draw a curve representing a function**

Description
Draw a curve representing a function.

Usage
```r
grid.function(...)  
functionGrob(f, n = 101, range = "x", units = "native",  
             name = NULL, gp=gpar(), vp = NULL)
```

grid.abline(intercept, slope, ...)

Arguments
- `f`  
  A function that must take a single argument and return a list with two numeric components named `x` and `y`.
- `n`  
  The number values that will be generated as input to the function `f`.
- `range`  
  Either "x", "y", or a numeric vector. See the ‘Details’ section.
- `units`  
  A string indicating the units to use for the `x` and `y` values generated by the function.
- `intercept`  
  Numeric.
- `slope`  
  Numeric.
- `...`  
  Arguments passed to `grid.function()`
- `name`  
  A character identifier.
- `gp`  
  An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp`  
  A Grid viewport object (or NULL).
Details

n values are generated and passed to the function f and a series of lines are drawn through the resulting x and y values.

The generation of the n values depends on the value of range. In the default case, dim is "x", which means that a set of x values are generated covering the range of the current viewport scale in the x-dimension. If dim is "y" then values are generated from the current y-scale instead. If range is a numeric vector, then values are generated from that range.

grid.abline() provides a simple front-end for a straight line parameterized by intercept and slope.

Value

A functiongrob grob.

grid.function(function(y) list(x=sin(y), y=y),
    range="y")
# parametric function
grid.newpage()
pushViewport(viewport(xscale=c(-1, 1), yscale=c(-1, 1)))
grid.function(function(t) list(x=cos(t), y=sin(t)),
    range=c(0, 9*pi/5))
grid.get

Get a Grid Graphical Object

Description
Retrieve a grob or a descendant of a grob.

Usage
grid.get(gPath, strict = FALSE, grep = FALSE, global = FALSE, allDevices = FALSE)
grid.gget(..., grep = TRUE, global = TRUE)
getGrob(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE)

Arguments
gTree A gTree object.
gPath A gPath object. For grid.get this specifies a grob on the display list. For getGrob this specifies a descendant of the specified gTree.
strict A boolean indicating whether the gPath must be matched exactly.
grep A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
... Arguments that are passed to grid.get.

Details
grid.gget (g for global) is just a convenience wrapper for grid.get with different defaults.

Value
A grob object.

Examples

grid.xaxis(name="xa")
grid.get("xa")
grid.get(gPath("xa", "ticks"))

grid.draw(gTree(name="gt", children=gList(xaxisGrob(name="axis"))))
grid.get(gPath("gt", "axis", "ticks"))

Description

Grabs the current grid output

Usage

grid.grab(warn = 2, wrap = FALSE, ...)  
grid.grabExpr(expr, warn = 2, wrap = FALSE, ...)

Arguments

expr An expression to be evaluated. Typically, some calls to grid drawing functions.

warn An integer specifying the amount of warnings to emit. 0 means no warnings, 1 means warn when it is certain that the grab will not faithfully represent the original scene. 2 means warn if there's any possibility that the grab will not faithfully represent the original scene.

wrap A logical indicating how the output should be captured. If TRUE, each non-grob element on the display list is captured by wrapping it in a grob.

... arguments passed to gTree, for example, a name and/or class for the gTree that is created.

Details

There are four ways to capture grid output as a gTree.

There are two functions for capturing output: use grid.grab to capture an existing drawing and grid.grabExpr to capture the output from an expression (without drawing anything).

For each of these functions, the output can be captured in two ways. One way tries to be clever and make a gTree with a childrenvp slot containing all viewports on the display list (including those that are popped) and every grob on the display list as a child of the new gTree; each child has a vpPath in the vp slot so that it is drawn in the appropriate viewport. In other words, the gTree contains all elements on the display list, but in a slightly altered form.

The other way, wrap=TRUE, is to create a grob for every element on the display list (and make all of those grobs children of the gTree).

The first approach creates a more compact and elegant gTree, which is more flexible to work with, but is not guaranteed to faithfully replicate all possible grid output. The second approach is more brute force, and harder to work with, but should always faithfully replicate the original output.
grid.grep

Search for grobs

Description

Given a gPath, find all matching grobs on the display list or within a given grob.

Usage

```r
grid.grep(path, x = NULL, grobs = TRUE, viewports = FALSE,
strict = FALSE, grep = FALSE, global = FALSE,
no.match = character())
```

Arguments

- `path` a gPath.
- `x` a grob or NULL. If NULL, the display list is searched.
- `grobs` A logical value indicating whether to search for grobs.
- `viewports` A logical value indicating whether to search for viewports.
- `strict` A boolean indicating whether the path must be matched exactly.
- `grep` Whether the path should be treated as a regular expression.
- `global` A boolean indicating whether the function should affect just the first match of the path, or whether all matches should be affected.
- `no.match` The value to return if no matches are found.

Value

Either a gPath or, if `global` is TRUE a list of gPaths. If there are no matches, `no.match` is returned.

---

### grid.grill

**Draw a Grill**

This function draws a grill within a Grid viewport.

**Usage**

```r
grid.grill(h = unit(seq(0.25, 0.75, 0.25), "npc"),
  v = unit(seq(0.25, 0.75, 0.25), "npc"),
  default.units = "npc", gp=gpar(col = "grey"), vp = NULL)
```

**Arguments**

- **h**: A numeric vector or unit object indicating the horizontal location of the vertical grill lines.
- **v**: A numeric vector or unit object indicating the vertical location of the horizontal grill lines.
- **default.units**: A string indicating the default units to use if h or v are only given as numeric vectors.
- **gp**: An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object.
grid.grob

Create Grid Graphical Objects, aka "Grob"s

Description
Creating grid graphical objects, short ("grob"s).
grob() and gTree() are the basic creators, grobTree() and gList() take several grobs to build a new one.

Usage
## Grob Creation:
grob(..., name = NULL, gp = NULL, vp = NULL, cl = NULL)
gTree(..., name = NULL, gp = NULL, vp = NULL, children = NULL,
   childrenvp = NULL, cl = NULL)
grobTree(..., name = NULL, gp = NULL, vp = NULL,
   childrenvp = NULL, cl = NULL)
gList(...) 

## Grob Properties:
childNames(gTree)
is.grob(x)

Arguments
... For grob and gTree, the named slots describing important features of the graphical object. For gList and grobTree, a series of grob objects.
name a character identifier for the grob. Used to find the grob on the display list and/or as a child of another grob.
children a "gList" object.
childrenvp a viewport object (or NULL).
gp A gpar object, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp a viewport object (or NULL).
cl string giving the class attribute for the new class.
gTree a "gTree" object.
x An R object.
Details

These functions can be used to create a basic "grob", "gTree", or "gList" object, or a new class derived from one of these.

A grid graphical object ("grob") is a description of a graphical item. These basic classes provide default behaviour for validating, drawing, and modifying graphical objects. Both grob() and gTree() call the function validDetails to check that the object returned is internally coherent.

A "gTree" can have other grobs as children; when a gTree is drawn, it draws all of its children. Before drawing its children, a gTree pushes its childrenvp slot and then navigates back up (calls upViewport) so that the children can specify their location within the childrenvp via a vpPath.

Grob names need not be unique in general, but all children of a gTree must have different names. A grob name can be any string, though it is not advisable to use the gPath separator (currently ::) in grob names.

The function childNames returns the names of the grobs which are children of a gTree.

All grid primitives (grid.lines, grid.rect, ...) and some higher-level grid components (e.g., grid.xaxis and grid.yaxis) are derived from these classes.

grobTree is just a convenient wrapper for gTree when the only components of the gTree are grobs (so all unnamed arguments become children of the gTree).

The grid.grob function is defunct.

Value

An R object of class "grob", a graphical object.

grid.draw, grid.edit, grid.get.

---

grid.layout Create a Grid Layout

Description

This function returns a Grid layout, which describes a subdivision of a rectangular region.

Usage

grid.layout(nrow = 1, ncol = 1,
    widths = unit(rep_len(1, ncol), "null"),
    heights = unit(rep_len(1, nrow), "null"),
    default.units = "null", respect = FALSE,
    just="centre")
Arguments

nrow  An integer describing the number of rows in the layout.
ncol  An integer describing the number of columns in the layout.
widths A numeric vector or unit object describing the widths of the columns in the layout.
heights A numeric vector or unit object describing the heights of the rows in the layout.
default.units A string indicating the default units to use if widths or heights are only given as numeric vectors.
respect A logical value or a numeric matrix. If a logical, this indicates whether row heights and column widths should respect each other. If a matrix, non-zero values indicate that the corresponding row and column should be respected (see examples below).
just A string or numeric vector specifying how the layout should be justified if it is not the same size as its parent viewport. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment. NOTE that in this context, "left", for example, means align the left edge of the left-most layout column with the left edge of the parent viewport.

Details

The unit objects given for the widths and heights of a layout may use a special units that only has meaning for layouts. This is the "null" unit, which indicates what relative fraction of the available width/height the column/row occupies. See the reference for a better description of relative widths and heights in layouts.

Value

A Grid layout object.

WARNING

This function must NOT be confused with the base R graphics function layout. In particular, do not use layout in combination with Grid graphics. The documentation for layout may provide some useful information and this function should behave identically in comparable situations. The grid.layout function has added the ability to specify a broader range of units for row heights and column widths, and allows for nested layouts (see viewport).

testlay(c("left", "bottom"))
testlay(c("left"))
testlay(c("right"))
testlay(c("bottom"))
testlay(c("top"))
```

---

grid.lines  

**Draw Lines in a Grid Viewport**

### Description

These functions create and draw a series of lines.

### Usage

```r
grid.lines(x = unit(c(0, 1), "npc"),
         y = unit(c(0, 1), "npc"),
         default.units = "npc",
         arrow = NULL, name = NULL,
         gp=gpar(), draw = TRUE, vp = NULL)
linesGrob(x = unit(c(0, 1), "npc"),
         y = unit(c(0, 1), "npc"),
         default.units = "npc",
         arrow = NULL, name = NULL,
         gp=gpar(), vp = NULL)
grid.polyline(...)
polylineGrob(x = unit(c(0, 1), "npc"),
             y = unit(c(0, 1), "npc"),
             id=NULL, id.lengths=NULL,
             default.units = "npc",
             arrow = NULL, name = NULL,
             gp=gpar(), vp = NULL)
```
Arguments

x  A numeric vector or unit object specifying x-values.
y  A numeric vector or unit object specifying y-values.
default.units  A string indicating the default units to use if x or y are only given as numeric vectors.
arrow  A list describing arrow heads to place at either end of the line, as produced by the arrow function.
name  A character identifier.
gp  An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw  A logical value indicating whether graphics output should be produced.
vp  A Grid viewport object (or NULL).
id  A numeric vector used to separate locations in x and y into multiple lines. All locations with the same id belong to the same line.
id.lengths  A numeric vector used to separate locations in x and y into multiple lines. Specifies consecutive blocks of locations which make up separate lines.
...  Arguments passed to polylineGrob.

Details

The first two functions create a lines grob (a graphical object describing lines), and grid.lines draws the lines (if draw is TRUE).
The second two functions create or draw a polyline grob, which is just like a lines grob, except that there can be multiple distinct lines drawn.

Value

A lines grob or a polyline grob. grid.lines returns a lines grob invisibly.

# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polyline(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
y=c(rep(.5, 5), (10:6/10), rep(.5, 5), (0:4)/10),
id=rep(1:5, 4),
gp=gpar(col=1:5, lwd=3))
# Using id.lengths
grid.newpage()
grid.polyline(x=outer(c(0, .5, 1, .5), 5:1/5),
y=outer(c(.5, 1, .5, 0), 5:1/5),
id.lengths=rep(4, 5),
gp=gpar(col=1:5, lwd=3))
Capture a Mouse Click

**Description**

Allows the user to click the mouse once within the current graphics device and returns the location of the mouse click within the current viewport, in the specified coordinate system.

**Usage**

```r
grid.locator(unit = "native")
```

**Arguments**

- `unit` The coordinate system in which to return the location of the mouse click. See the `unit` function for valid coordinate systems.

**Details**

This function is modal (like the graphics package function `locator`) so the command line and graphics drawing is blocked until the user has clicked the mouse in the current device.

**Value**

A unit object representing the location of the mouse click within the current viewport, in the specified coordinate system.

If the user did not click mouse button 1, the function (invisibly) returns `NULL`.

**Author(s)**

Paul Murrell

**See Also**

- `viewport`, `unit`, `locator` in package `graphics`, and for an application see `trellis.focus` and `panel.identify` in package `lattice`.

**Examples**

```r
if (dev.interactive()) {
  ## Need to write a more sophisticated unit as.character method
  unittrim <- function(unit) {
    sub("^[0-9]+([0-9]+[.][0-9]+)?\", \"\\1\", as.character(unit))
  }
  do.click <- function(unit) {
    click.locn <- grid.locator(unit)
    grid.segments(unit.c(click.locn$x, unit(0, "npc")),
                  unit.c(unit(0, "npc"), click.locn$y),
                  unit.c(unit(0, "npc"), click.locn$y),
                  gp=gpar(lty="dashed", col="grey"))
    grid.points(click.locn$x, click.locn$y, pch=16, size=unit(1, "mm"))
    clickx <- unittrim(click.locn$x)
    clicky <- unittrim(click.locn$y)
  }
  do.click("native")
}
```
grid.ls

List the names of grobs or viewports

Description

Return a listing of the names of grobs or viewports.

This is a generic function with methods for grobs (including gTrees) and viewports (including vpTrees).

Usage

grid.ls(x=NULL, grobs=TRUE, viewports=FALSE, fullNames=FALSE, recursive=TRUE, print=TRUE, flatten=TRUE, ...)

nestedListing(x, gindent=" ", vpindent=gindent)
pathListing(x, gvpSep=" | ", gAlign=TRUE)
grobPathListing(x, ...)

Arguments

x A grob or viewport or NULL. If NULL, the current grid display list is listed. For print functions, this should be the result of a call to grid.ls.
grobs A logical value indicating whether to list grobs.
viewports A logical value indicating whether to list viewports.
fullNames A logical value indicating whether to embellish object names with information about the object type.
recursive A logical value indicating whether recursive structures should also list their children.
print A logical indicating whether to print the listing or a function that will print the listing.
flatten A logical value indicating whether to flatten the listing. Otherwise a more complex hierarchical object is produced.
grid.ls

gindent
The indent used to show nesting in the output for grobs.

vpindent
The indent used to show nesting in the output for viewports.

gvpSep
The string used to separate viewport paths from grob paths.

gAlign
Logical indicating whether to align the left hand edge of all grob paths.

... Arguments passed to the print function.

Details
If the argument x is NULL, the current contents of the grid display list are listed (both viewports and
grobs). In other words, all objects representing the current scene are listed.
Otherwise, x should be a grob or a viewport.
The default behaviour of this function is to print information about the grobs in the current scene.
It is also possible to add information about the viewports in the scene. By default, the listing is
recursive, so all children of gTrees and all nested viewports are reported.
The format of the information can be controlled via the print argument, which can be given a
function to perform the formatting. The nestedListing function produces a line per grob or view-
port, with indenting used to show nesting. The pathListing function produces a line per grob or
viewport, with viewport paths and grob paths used to show nesting. The grobPathListing is a
simple derivation that only shows lines for grobs. The user can define new functions.

Value
The result of this function is either a "gridFlatListing" object (if flatten is TRUE) or a
"gridListing" object.
The former is a simple (flat) list of vectors. This is convenient, for example, for working program-
matically with the list of grob and viewport names, or for writing a new display function for the
listing.
The latter is a more complex hierarchical object (list of lists), but it does contain more detailed
information so may be of use for more advanced customisations.

Examples
# A gTree, called "parent", with children vp Tree (vp2 within vp1)
# and child grob, called "child", with vp vp Path (down to vp2)
sampleGTree <- gTree(name="parent",
children=gList(grob(name="child", vp="vp1::vp2")),
childrenvp=vpTree(parent=viewport(name="vp1"),
children=vpList(viewport(name="vp2"))))
grid.ls(sampleGTree)
# Show viewports too
grid.ls(sampleGTree, view=TRUE)
# Only show viewports
grid.ls(sampleGTree, view=TRUE, grob=FALSE)
# Alternate displays
# nested listing, custom indent
grid.ls(sampleGTree, view=TRUE, print=nestedListing, gindent="--")
# path listing
grid.ls(sampleGTree, view=TRUE, print=pathListing)
# path listing, without grobs aligned
grid.ls(sampleGTree, view=TRUE, print=pathListing, gAlign=FALSE)
# grob path listing
grid.ls(sampleGTree, view=TRUE, print=grobPathListing)
# path listing, grobs only
grid.ls(sampleGTree, print=pathListing)
# path listing, viewports only
grid.ls(sampleGTree, view=TRUE, grob=FALSE, print=pathListing)
# raw flat listing
str(grid.ls(sampleGTree, view=TRUE, print=FALSE))

grid.move.to

## Move or Draw to a Specified Position

### Description

Grid has the notion of a current location. These functions sets that location.

### Usage

```r
grid.move.to(x = 0, y = 0, default.units = "npc", name = NULL, 
draw = TRUE, vp = NULL)
```

```r
moveToGrob(x = 0, y = 0, default.units = "npc", name = NULL, 
vp = NULL)
```

```r
grid.line.to(x = 1, y = 1, default.units = "npc", 
arrow = NULL, name = NULL, 
gp = gpar(), draw = TRUE, vp = NULL)
```

```r
lineToGrob(x = 1, y = 1, default.units = "npc", arrow = NULL, 
name = NULL, gp = gpar(), vp = NULL)
```

### Arguments

- **x**: A numeric value or a unit object specifying an x-value.
- **y**: A numeric value or a unit object specifying a y-value.
- **default.units**: A string indicating the default units to use if x or y are only given as numeric values.
- **arrow**: A list describing arrow heads to place at either end of the line, as produced by the arrow function.
- **name**: A character identifier.
- **draw**: A logical value indicating whether graphics output should be produced.
- **gp**: An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **vp**: A Grid viewport object (or NULL).
Details
Both functions create a move.to/line.to grob (a graphical object describing a move-to/line-to), but only `grid.move.to/line.to()` draws the move.to/line.to (and then only if `draw` is `TRUE`).

Value
A move.to/line.to grob. `grid.move.to/line.to()` returns the value invisibly.

Author(s)
Paul Murrell

See Also
`Grid, viewport, arrow`

Examples
```r
grid.newpage()
grid.move.to(0.5, 0.5)
grid.line.to(1, 1)
grid.line.to(0.5, 0)
pushViewport(viewport(x=0, y=0, w=0.25, h=0.25, just=c("left", "bottom")))
grid.rect()
grid.grill()
grid.line.to(0.5, 0.5)
popViewport()
```

Description
This function erases the current device or moves to a new page.

Usage
```
grid.newpage(recording = TRUE)
```

Arguments
- `recording` A logical value to indicate whether the new-page operation should be saved onto the Grid display list.

Details
The new page is painted with the fill colour (`gpar("fill")`), which is often transparent. For devices with a `canvas` colour (the on-screen devices `X11`, `windows` and `quartz`), the page is first painted with the canvas colour and then the background colour.

There are two hooks called "before.grid.newpage" and "grid.newpage" (see `setHook`). The latter is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, `get` is called on it from within the `grid` namespace.)
Value

None.

Author(s)

Paul Murrell

See Also

Grid

Description

These functions create a NULL graphical object, which has zero width, zero height, and draw nothing. It can be used as a place-holder or as an invisible reference point for other drawing.

Usage

nullGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
default.units = "npc",
name = NULL, vp = NULL)
grid.null(...)

Arguments

x A numeric vector or unit object specifying x-location.
y A numeric vector or unit object specifying y-location.
default.units A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name A character identifier.
vp A Grid viewport object (or NULL).
... Arguments passed to nullGrob().

Value

A null grob.

Author(s)

Paul Murrell

See Also

Grid, viewport
Examples

```r
grid.newpage()
grid.null(name="ref")
grid.rect(height=grobHeight("ref"))
grid.segments(0, 0, grobX("ref", 0), grobY("ref", 0))
```

---

**grid.pack**

Pack an Object within a Frame

Description

These functions, together with `grid.frame` and `frameGrob` are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with `grid.frame` or `frameGrob` then use these functions to pack objects into the frame.

Usage

```r
grid.pack(gPath, grob, redraw = TRUE, side = NULL,
          row = NULL, row.before = NULL, row.after = NULL,
          col = NULL, col.before = NULL, col.after = NULL,
          width = NULL, height = NULL,
          force.width = FALSE, force.height = FALSE, border = NULL,
          dynamic = FALSE)
```

```
packGrob(frame, grob, side = NULL,
         row = NULL, row.before = NULL, row.after = NULL,
         col = NULL, col.before = NULL, col.after = NULL,
         width = NULL, height = NULL,
         force.width = FALSE, force.height = FALSE, border = NULL,
         dynamic = FALSE)
```

Arguments

- **gPath**: A `gPath` object, which specifies a frame on the display list.
- **frame**: An object of class `frame`, typically the output from a call to `grid.frame`.
- **grob**: An object of class `grob`. The object to be packed.
- **redraw**: A boolean indicating whether the output should be updated.
- **side**: One of "left", "top", "right", "bottom" to indicate which side to pack the object on.
- **row**: Which row to add the object to. Must be between 1 and the number of rows currently in the frame + 1, or NULL in which case the object occupies all rows.
- **row.before**: Add the object to a new row just before this row.
- **row.after**: Add the object to a new row just after this row.
- **col**: Which col to add the object to. Must be between 1 and the number of cols currently in the frame + 1, or NULL in which case the object occupies all cols.
- **col.before**: Add the object to a new col just before this col.
- **col.after**: Add the object to a new col just after this col.
grid.path

width
Specifies the width of the column that the object is added to (rather than allowing the width to be taken from the object).

height
Specifies the height of the row that the object is added to (rather than allowing the height to be taken from the object).

force.width
A logical value indicating whether the width of the column that the grob is being packed into should be EITHER the width specified in the call to grid.pack OR the maximum of that width and the pre-existing width.

force.height
A logical value indicating whether the height of the column that the grob is being packed into should be EITHER the height specified in the call to grid.pack OR the maximum of that height and the pre-existing height.

border
A unit object of length 4 indicating the borders around the object.

dynamic
If the width/height is taken from the grob being packed, this boolean flag indicates whether the grobwidth/height unit refers directly to the grob, or uses a gPath to the grob. In the latter case, changes to the grob will trigger a recalculation of the width/height.

Details
packGrob modifies the given frame grob and returns the modified frame grob.

grid.pack destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

These are (meant to be) very flexible functions. There are many different ways to specify where the new object is to be added relative to the objects already in the frame. The function checks that the specification is not self-contradictory.

NOTE that the width/height of the row/col that the object is added to is taken from the object itself unless the width/height is specified.

Value
packGrob returns a frame grob, but grid.pack returns NULL.

Author(s)
Paul Murrell

See Also
grid.frame, grid.place, grid.edit, and gPath.

grid.path  Draw a Path

Description
These functions create and draw a path. The final point will automatically be connected to the initial point.
Usage

grid.path(x, y, id=NULL, id.lengths=NULL, rule="winding", default.units="npc", name=NULL, gp=gpar(), vp=NULL)

Arguments

x A numeric vector or unit object specifying x-locations.
y A numeric vector or unit object specifying y-locations.
id A numeric vector used to separate locations in x and y into sub-paths. All locations with the same id belong to the same sub-path.
id.lengths A numeric vector used to separate locations in x and y into sub-paths. Specifies consecutive blocks of locations which make up separate sub-paths.
rule A character value specifying the fill rule: either "winding" or "evenodd".
default.units A string indicating the default units to use if x or y are only given as numeric vectors.
name A character identifier.
gp An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
... Arguments passed to pathGrob().

Details

Both functions create a path grob (a graphical object describing a path), but only grid.path draws the path (and then only if draw is TRUE).

A path is like a polygon except that the former can contain holes, as interpreted by the fill rule; these fill a region if the path border encircles it an odd or non-zero number of times, respectively.

Not all graphics devices support this function: for example xfig and pictex do not.

Value

A grob object.

              "Nested rectangles, outer clockwise, inner anti-clockwise")
  popViewport()
  pushViewport(viewport(layout.pos.row = 3))
  pathTriplet(c(.1, .1, .4, .4, .6, .9, .9, .6),
              c(.1, .4, .4, .1, .6, .6, .9, .9),
              "Disjoint rectangles")
  popViewport()
  pushViewport(viewport(layout.pos.row = 4))
  pathTriplet(c(.1, .1, .6, .6, .4, .4, .9, .9),
              c(.1, .6, .6, .4, .9, .9, .4),
              "Overlapping rectangles, both clockwise")
  popViewport()
  pushViewport(viewport(layout.pos.row = 5))
  pathTriplet(c(.1, .1, .6, .6, .4, .9, .9, .4),
              c(.1, .6, .6, .1, .4, .4, .9, .9),
```
grid.place

"Overlapping rectangles, one clockwise, other anti-clockwise")

popViewport()
popViewport()
}

pathTest()

---

grid.place  Place an Object within a Frame

Description

These functions provide a simpler (and faster) alternative to the grid.pack() and packGrob functions. They can be used to place objects within the existing rows and columns of a frame layout. They do not provide the ability to add new rows and columns nor do they affect the heights and widths of the rows and columns.

Usage

grid.place(gPath, grob, row = 1, col = 1, redraw = TRUE)
placeGrob(frame, grob, row = NULL, col = NULL)

Arguments

gPath  A gPath object, which specifies a frame on the display list.
frame  An object of class frame, typically the output from a call to grid.frame.
grob  An object of class grob. The object to be placed.
row  Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame.
col  Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame.
redraw  A boolean indicating whether the output should be updated.

Details

placeGrob modifies the given frame grob and returns the modified frame grob.
grid.place destructively modifies a frame grob on the display list (and redraws the display list if redraw is TRUE).

Value

placeGrob returns a frame grob, but grid.place returns NULL.

grid.plot.and.legend  

A Simple Plot and Legend Demo

Description
This function is just a wrapper for a simple demonstration of how a basic plot and legend can be
drawn from scratch using grid.

Usage
grid.plot.and.legend()

Author(s)
Paul Murrell

Examples
grid.plot.and.legend()

grid.points  

Draw Data Symbols

Description
These functions create and draw data symbols.

Usage
grid.points(x = stats::runif(10),
         y = stats::runif(10),
         pch = 1, size = unit(1, "char"),
         default.units = "native", name = NULL,
         gp = gpar(), draw = TRUE, vp = NULL)
pointsGrob(x = stats::runif(10),
          y = stats::runif(10),
          pch = 1, size = unit(1, "char"),
          default.units = "native", name = NULL,
          gp = gpar(), vp = NULL)

Arguments
x     numeric vector or unit object specifying x-values.
y     numeric vector or unit object specifying y-values.
pch  numeric or character vector indicating what sort of plotting symbol to use. See points for the interpretation of these values, and note fill below.
size  unit object specifying the size of the plotting symbols.
default.units string indicating the default units to use if x or y are only given as numeric vectors.
name character identifier.

gp an R object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings; note that fill (and not bg as in package graphics points) is used to “fill”, i.e., color the background of symbols with pch = 21:25.

draw logical indicating whether graphics output should be produced.

vp A Grid viewport object (or NULL).

Details
Both functions create a points grob (a graphical object describing points), but only grid.points draws the points (and then only if draw is TRUE).

Value
A points grob. grid.points returns the value invisibly.

gird.polygon Draw a Polygon

description
These functions create and draw a polygon. The final point will automatically be connected to the initial point.

Usage
grid.polygon(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
id=NULL, id.lengths=NULL,
default.units="npc", name=NULL,
gp=gpar(), draw=TRUE, vp=NULL)
polygonGrobi(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
id=NULL, id.lengths=NULL,
default.units="npc", name=NULL,
gp=gpar(), vp=NULL)
Arguments

x  A numeric vector or unit object specifying x-locations.
y  A numeric vector or unit object specifying y-locations.
id  A numeric vector used to separate locations in x and y into multiple polygons. All locations with the same id belong to the same polygon.
id.lengths  A numeric vector used to separate locations in x and y into multiple polygons. Specifies consecutive blocks of locations which make up separate polygons.
default.units  A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name  A character identifier.
gp  An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw  A logical value indicating whether graphics output should be produced.
vp  A Grid viewport object (or NULL).

Details

Both functions create a polygon grob (a graphical object describing a polygon), but only grid.polygon draws the polygon (and then only if draw is TRUE).

Value

A grob object.

Author(s)

Paul Murrell

grid.polygon(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
     y=c(rep(.5, 5), (10:6)/10, rep(.5, 5), (0:4)/10),
     id=rep(1:5, 4),
     gp=gpar(fill=1:5))
# Using id.lengths
grid.newpage()
grid.polygon(x=outer(c(0, .5, 1, .5), 5:1/5),
     y=outer(c(.5, 1, .5, 0), 5:1/5),
     id.lengths=rep(4, 5),
     gp=gpar(fill=1:5))
grid.pretty  

Generate a Sensible Set of Breakpoints

Description

Produces a pretty set of breakpoints within the range given.

Usage

grid.pretty(range)

Arguments

- range: A numeric vector

Value

A numeric vector of breakpoints.

Author(s)

Paul Murrell

grid.raster  

Render a raster object

Description

Render a raster object (bitmap image) at the given location, size, and orientation.

Usage

grid.raster(image,  
x = unit(0.5, "npc"), y = unit(0.5, "npc"),  
width = NULL, height = NULL,  
just = "centre", hjust = NULL, vjust = NULL,  
interpolate = TRUE, default.units = "npc",  
name = NULL, gp = gpar(), vp = NULL)

rasterGrob(image,  
x = unit(0.5, "npc"), y = unit(0.5, "npc"),  
width = NULL, height = NULL,  
just = "centre", hjust = NULL, vjust = NULL,  
interpolate = TRUE, default.units = "npc",  
name = NULL, gp = gpar(), vp = NULL)
Arguments

image Any R object that can be coerced to a raster object.
x A numeric vector or unit object specifying x-location.
y A numeric vector or unit object specifying y-location.
width A numeric vector or unit object specifying width.
height A numeric vector or unit object specifying height.
just The justification of the rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
hjust A numeric vector specifying horizontal justification. If specified, overrides the just setting.
vjust A numeric vector specifying vertical justification. If specified, overrides the just setting.
default.units A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name A character identifier.
gp An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
interpolate A logical value indicating whether to linearly interpolate the image (the alternative is to use nearest-neighbour interpolation, which gives a more blocky result).

Details

Neither width nor height needs to be specified, in which case, the aspect ratio of the image is preserved. If both width and height are specified, it is likely that the image will be distorted.

Not all graphics devices are capable of rendering raster images and some may not be able to produce rotated images (i.e., if a raster object is rendered within a rotated viewport). See also the comments under rasterImage.

All graphical parameter settings in gp will be ignored, including alpha.

Value

A rastergrob grob.

Author(s)

Paul Murrell

```r
redGradient <- matrix(hcl(0, 80, seq(50, 80, 10)),
                      nrow=4, ncol=5)
# interpolated
grid.newpage()
grid.raster(redGradient)
# blocky
grid.newpage()
grid.raster(redGradient, interpolate=FALSE)
# blocky and stretched
grid.newpage()
grid.raster(redGradient, interpolate=FALSE, height=unit(1, "npc"))

# The same raster drawn several times
grid.newpage()
grid.raster(0, x=1:3/4, y=1:3/4, w=.1, interp=FALSE)
```

grid.record

Encapsulate calculations and drawing

Description

Evaluates an expression that includes both calculations and drawing that depends on the calculations so that both the calculations and the drawing will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended only for expert use.

Usage

```r
recordGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.record(expr, list, name=NULL, gp=NULL, vp=NULL)
```

Arguments

- `expr` object of mode `expression` or call or an unevaluated expression.
- `list` a list defining the environment in which `expr` is to be evaluated.
- `name` A character identifier.
- `gp` An object of class `gpar`, typically the output from a call to the function `gpar`. This is basically a list of graphical parameter settings.
- `vp` A Grid viewport object (or NULL).

Details

A grob is created of special class "recordedGrob" (and drawn, in the case of `grid.record`). The `drawDetails` method for this class evaluates the expression with the list as the evaluation environment (and the grid Namespace as the parent of that environment).

Note

This function must be used instead of the function `recordGraphics`; all of the dire warnings about using `recordGraphics` responsibly also apply here.
grid.rect

Draw rectangles

These functions create and draw rectangles.

Usage

```r
grid.rect(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
          width = unit(1, "npc"), height = unit(1, "npc"),
          just = "centre", hjust = NULL, vjust = NULL,
          default.units = "npc", name = NULL,
          gp=gpar(), draw = TRUE, vp = NULL)
rectGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
         width = unit(1, "npc"), height = unit(1, "npc"),
         just = "centre", hjust = NULL, vjust = NULL,
         default.units = "npc", name = NULL,
         gp=gpar(), vp = NULL)
```

Arguments

- `x` A numeric vector or unit object specifying x-location.
- `y` A numeric vector or unit object specifying y-location.
- `width` A numeric vector or unit object specifying width.
- `height` A numeric vector or unit object specifying height.
- `just` The justification of the rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
- `hjust` A numeric vector specifying horizontal justification. If specified, overrides the just setting.
- `vjust` A numeric vector specifying vertical justification. If specified, overrides the just setting.

Description

See Also

- `recordGraphics`

Examples

```r
grid.record(
  w <- convertWidth(unit(1, "inches"), "npc")
  grid.rect(width=w)
),
list())
```
default.units A string indicating the default units to use if \(x, y, \text{width},\) or \(\text{height}\) are only given as numeric vectors.

name A character identifier.

gp An object of class \texttt{gpar}, typically the output from a call to the function \texttt{gpar}. This is basically a list of graphical parameter settings.

draw A logical value indicating whether graphics output should be produced.

vp A Grid viewport object (or NULL).

Details

Both functions create a rect grob (a graphical object describing rectangles), but only \texttt{grid.rect} draws the rectangles (and then only if \text{draw} is \texttt{TRUE}).

Value

A rect grob. \texttt{grid.rect} returns the value invisibly.

\begin{verbatim}
grid.refresh

Refresh the current grid scene

Description

Replays the current grid display list.

Usage

\texttt{grid.refresh()}\n
Author(s)

Paul Murrell
\end{verbatim}
Remove a Grid Graphical Object

Description
Remove a grob from a gTree or a descendant of a gTree.

Usage
grid.remove(gPath, warn = TRUE, strict = FALSE, grep = FALSE,
global = FALSE, allDevices = FALSE, redraw = TRUE)
grid.gremove(..., grep = TRUE, global = TRUE)
removeGrob(gTree, gPath, strict = FALSE, grep = FALSE,
global = FALSE, warn = TRUE)

Arguments
gTree A gTree object.
gPath a gPath object. For grid.remove this specifies a gTree on the display list. For removeGrob this specifies a descendant of the specified gTree.
strict a logical indicating whether the gPath must be matched exactly.
grep a logical indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global a logical indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices a logical indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
warn A logical to indicate whether failing to find the specified grob should trigger an error.
redraw A logical value to indicate whether to redraw the grob.
... arguments passed to grid.get.

Details
removeGrob copies the specified grob and returns a modified grob.
grid.remove destructively modifies a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.
grid.gremove (g for global) is just a convenience wrapper for grid.remove with different defaults.

Value
removeGrob returns a grob object; grid.remove returns NULL.
grid.reorder

Reorder the children of a gTree

Description

Change the order in which the children of a gTree get drawn.

Usage

grid.reorder(gPath, order, back=TRUE, grep=FALSE, redraw=TRUE)
reorderGrob(x, order, back=TRUE)

Arguments

gPath A gPath object specifying a gTree within the current scene.
x A gTree object to be modified.
order A character vector or a numeric vector that specifies the new drawing order for
the children of the gTree. May not refer to all children of the gTree (see Details).
back Controls what happens when the order does not specify all children of the gTree
(see Details).
grep Should the gPath be treated as a regular expression?
redraw Should the modified scene be redrawn?

Details

In the simplest case, order specifies a new ordering for all of the children of the gTree. The children may be specified either by name or by existing numerical order.

If the order does not specify all children of the gTree then, by default, the children specified by order are drawn first and then all remaining children are drawn. If back=FALSE then the children not specified in order are drawn first, followed by the specified children. This makes it easy to specify a send-to-back or bring-to-front reordering. The order argument is always in back-to-front order.

It is not possible to reorder the grid display list (the top-level grobs in the current scene) because the display list is a mixture of grobs and viewports (so it is not clear what reordering even means and it would be too easy to end up with a scene that would not draw). If you want to reorder the grid display list, try grid.grab() to create a gTree and then reorder (and redraw) that gTree.

Value

grid.reorder() is called for its side-effect of modifying the current scene. reorderGrob() returns the modified gTree.
Warning

This function may return a gTree that will not draw. For example, a gTree has two children, A and B (in that order), and the width of child B depends on the width of child A (e.g., a box around a piece of text). Switching the order so that B is drawn before A will not allow B to be drawn. If this happens with `grid.reorder()`, the modification will not be performed. If this happens with `reorderGrob()` it should be possible simply to restore the original order.

Author(s)

Paul Murrell

Examples

# gTree with two children, "red-rect" and "blue-rect" (in that order)
gt <- gTree(children=gList(
    rectGrob(gp=gpar(col=NA, fill="red"),
    width=.8, height=.2, name="red-rect"),
    rectGrob(gp=gpar(col=NA, fill="blue"),
    width=.2, height=.8, name="blue-rect")),
    name="gt")
grid.newpage()
grid.draw(gt)
# Spec entire order as numeric (blue-rect, red-rect)
grid.reorder("gt", 2:1)
# Spec entire order as character
grid.reorder("gt", c("red-rect", "blue-rect"))
# Only spec the one I want behind as character
grid.reorder("gt", "blue-rect")
# Only spec the one I want in front as character
grid.reorder("gt", "blue-rect", back=FALSE)
grid.set

Set a Grid Graphical Object

Description

Replace a grob or a descendant of a grob.

Usage

grid.set(gPath, newGrob, strict = FALSE, grep = FALSE,
        redraw = TRUE)

setGrob(gTree, gPath, newGrob, strict = FALSE, grep = FALSE)
grid.show.layout

Arguments

- **gTree**: A gTree object.
- **gPath**: A gPath object. For grid.set this specifies a grob on the display list. For setGrob this specifies a descendant of the specified gTree.
- **newGrob**: A grob object.
- **strict**: A boolean indicating whether the gPath must be matched exactly.
- **grep**: A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
- **redraw**: A logical value to indicate whether to redraw the grob.

Details

setGrob copies the specified grob and returns a modified grob.

grid.set destructively replaces a grob on the display list. If redraw is TRUE it then redraws everything to reflect the change.

These functions should not normally be called by the user.

Value

setGrob returns a grob object; grid.set returns NULL.

grid.grob.

grid.show.layout

Draw a Diagram of a Grid Layout

Description

This function uses Grid graphics to draw a diagram of a Grid layout.

Usage

grid.show.layout(l, newpage=TRUE, vp.ex = 0.8, bg = "light grey", cell.border = "blue", cell.fill = "light blue", cell.label = TRUE, label.col = "blue", unit.col = "red", vp = NULL, ...)
Arguments

1  A Grid layout object.
newpage  A logical value indicating whether to move on to a new page before drawing the diagram.
vp.ex  positive number, typically in (0, 1], specifying the scaling of the layout.
bg  The colour used for the background.
cell.border  The colour used to draw the borders of the cells in the layout.
cell.fill  The colour used to fill the cells in the layout.
cell.label  A logical indicating whether the layout cells should be labelled.
label.col  The colour used for layout cell labels.
unit.col  The colour used for labelling the widths/heights of columns/rows.
vp  A Grid viewport object (or NULL).
...  Arguments passed to format for formatting the layout width and height annotations.

Details

A viewport is created within vp to provide a margin for annotation, and the layout is drawn within that new viewport. The margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the layout regions are filled with light blue and framed with a blue border. The diagram is annotated with the widths and heights (including units) of the columns and rows of the layout using red text. (All colours are defaults and may be customised via function arguments.)

Value

None.

Examples

## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
  heights=unit(rep(1, 4),
    c("lines", "lines", "lines", "null")),
  widths=unit(c(1, 1), "inches")))
grid.show.viewport  

**Draw a Diagram of a Grid Viewport**

**Description**

This function uses Grid graphics to draw a diagram of a Grid viewport.

**Usage**

```r
grid.show.viewport(v, parent.layout = NULL, newpage = TRUE,
           vp.ex = 0.8, border.fill="light grey",
           vp.col="blue", vp.fill="light blue",
           scale.col="red",
           vp = NULL)
```

**Arguments**

- **v**: A Grid viewport object.
- **parent.layout**: A grid layout object. If this is not NULL and the viewport given in `v` has its location specified relative to the layout, then the diagram shows the layout and which cells `v` occupies within the layout.
- **newpage**: A logical value to indicate whether to move to a new page before drawing the diagram.
- **vp.ex**: Positive number, typically in (0, 1], specifying the scaling of the layout.
- **border.fill**: Colour to fill the border margin.
- **vp.col**: Colour for the border of the viewport region.
- **vp.fill**: Colour to fill the viewport region.
- **scale.col**: Colour to draw the viewport axes.
- **vp**: A Grid viewport object (or NULL).

**Details**

A viewport is created within `vp` to provide a margin for annotation, and the diagram is drawn within that new viewport. By default, the margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the viewport region is filled with light blue and framed with a blue border. The diagram is annotated with the width and height (including units) of the viewport, the (x, y) location of the viewport, and the x- and y-scales of the viewport, using red lines and text.

**Value**

None.

**Author(s)**

Paul Murrell

**See Also**

- `Grid`, `viewport`
Examples

```r
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
    w=unit(1, "inches"), h=unit(1, "inches")))
grid.show.viewport(viewport(layout.pos.row=2, layout.pos.col=2:3),
    grid.layout(3, 4))
```

Usage

```r
grid.text(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
    just = "centre", hjust = NULL, vjust = NULL, rot = 0,
    check.overlap = FALSE, default.units = "npc",
    name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
textGrob(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
    just = "centre", hjust = NULL, vjust = NULL, rot = 0,
    check.overlap = FALSE, default.units = "npc",
    name = NULL, gp = gpar(), vp = NULL)
```

Arguments

- **label**: A character or expression vector. Other objects are coerced by `as.graphicsAnnot`.
- **x**: A numeric vector or unit object specifying x-values.
- **y**: A numeric vector or unit object specifying y-values.
- **just**: The justification of the text relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left (bottom) alignment and 1 means right (top) alignment.
- **hjust**: A numeric vector specifying horizontal justification. If specified, overrides the just setting.
- **vjust**: A numeric vector specifying vertical justification. If specified, overrides the just setting.
- **rot**: The angle to rotate the text.
- **check.overlap**: A logical value to indicate whether to check for and omit overlapping text.
- **default.units**: A string indicating the default units to use if x or y are only given as numeric vectors.
- **name**: A character identifier.
- **gp**: An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
- **draw**: A logical value indicating whether graphics output should be produced.
- **vp**: A Grid viewport object (or NULL).

Description

These functions create and draw text and plotmath expressions.
Details

Both functions create a text grob (a graphical object describing text), but only `grid.text` draws the text (and then only if `draw` is `TRUE`).

If the `label` argument is an expression, the output is formatted as a mathematical annotation, as for base graphics text.

Value

A text grob. `grid.text()` returns the value invisibly.

grid.newpage()
x <- stats::runif(20)
y <- stats::runif(20)
rot <- stats::runif(20, 0, 360)
grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
gp=gpar(fontsize=20, col="grey"))
grid.text("SOMETHING NICE AND BIG", x=x, y=y, rot=rot,
gp=gpar(fontsize=20), check=TRUE)
grid.newpage()
draw.text <- function(just, i, j) {
  grid.text("ABCD", x=x[j], y=y[i], just=just)
  grid.text(deparse(substitute(just)), x=x[j], y=y[i] + unit(2, "lines"),
            gp=gpar(col="grey", fontsize=8))
}
x <- unit(1:4/5, "npc")
y <- unit(1:4/5, "npc")
grid.grill(h=y, v=x, gp=gpar(col="grey"))
draw.text(c("bottom"), 1, 1)
draw.text(c("left", "bottom"), 2, 1)
draw.text(c("right", "bottom"), 3, 1)
draw.text(c("centre", "bottom"), 4, 1)
draw.text(c("centre"), 1, 2)
draw.text(c("left", "centre"), 2, 2)
draw.text(c("right", "centre"), 3, 2)
draw.text(c("centre", "centre"), 4, 2)
draw.text(c("top"), 1, 3)
draw.text(c("left", "top"), 2, 3)
draw.text(c("right", "top"), 3, 3)
draw.text(c("centre", "top"), 4, 3)
draw.text(c(), 1, 4)
draw.text(c("left"), 2, 4)
draw.text(c("right"), 3, 4)
draw.text(c("centre"), 4, 4)
```

**grid.xaxis**  

**Draw an X-Axis**

**Description**

These functions create and draw an x-axis.

**Usage**

```r
grid.xaxis(at = NULL, label = TRUE, main = TRUE, 
edits = NULL, name = NULL, 
gp = gpar(), draw = TRUE, vp = NULL)
```

```r
xaxisGrob(at = NULL, label = TRUE, main = TRUE, 
edits = NULL, name = NULL, 
gp = gpar(), vp = NULL)
```

**Arguments**

- **at**
  A numeric vector of x-value locations for the tick marks.

- **label**
  A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.

- **main**
  A logical value indicating whether to draw the axis at the bottom (TRUE) or at the top (FALSE) of the viewport.

- **edits**
  A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.

- **name**
  A character identifier.

- **gp**
  An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

- **draw**
  A logical value indicating whether graphics output should be produced.

- **vp**
  A Grid viewport object (or NULL).

**Details**

Both functions create an xaxis grob (a graphical object describing an xaxis), but only `grid.xaxis` draws the xaxis (and then only if `draw` is TRUE).

**Value**

An xaxis grob. `grid.xaxis` returns the value invisibly.

**Children**

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

- **major** representing the line at the base of the tick marks.
- **ticks** representing the tick marks.
- **labels** representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.
grid.xspline

Draw an Xspline

Description

These functions create and draw an xspline, a curve drawn relative to control points.

Usage

grid.xspline(...)
xsplineGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),
id = NULL, id.lengths = NULL,
default.units = "npc",
shape = 0, open = TRUE, arrow = NULL, repEnds = TRUE,
name = NULL, gp = gpar(), vp = NULL)

Arguments

x A numeric vector or unit object specifying x-locations of spline control points.
y A numeric vector or unit object specifying y-locations of spline control points.
id A numeric vector used to separate locations in x and y into multiple xsplines. All locations with the same id belong to the same xspline.
id.lengths A numeric vector used to separate locations in x and y into multiple xsplines. Specifies consecutive blocks of locations which make up separate xsplines.
default.units A string indicating the default units to use if x or y are only given as numeric vectors.
shape A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
open A logical value indicating whether the spline is a line or a closed shape.
arrow A list describing arrow heads to place at either end of the xspline, as produced by the arrow function.
repEnds A logical value indicating whether the first and last control points should be replicated for drawing the curve (see Details below).
name A character identifier.
gp An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
vp A Grid viewport object (or NULL).
... Arguments to be passed to xsplineGrob.
Both functions create an xspline grob (a graphical object describing an xspline), but only `grid.xspline` draws the xspline.

An xspline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open xsplines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero without warning).

For open xsplines, by default the start and end control points are actually replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the `repEnds` argument, in which case the curve that is drawn starts (approximately) at the second control point and ends (approximately) at the first and second-to-last control point.

The `repEnds` argument is ignored for closed xsplines.

Missing values are not allowed for `x` and `y` (i.e., it is not valid for a control point to be missing).

For closed xsplines, a curve is automatically drawn between the final control point and the initial control point.

### Value

A grob object.

### References

### See Also

`Grid`, `viewport`, `arrow`, `xspline`.

### Examples

```r
x <- c(0.25, 0.25, 0.75, 0.75)
y <- c(0.25, 0.75, 0.75, 0.25)
xplineTest <- function(s, i, j, open) {
  pushViewport(viewport(layout.pos.col=j, layout.pos.row=i))
  grid.points(x, y, default.units="npc", pch=16, size=unit(2, "mm"))
  grid.xspline(x, y, shape=s, open=open, gp=gpar(fill="grey"))
  grid.text(s, gp=gpar(col="grey"),
            x=unit(x, "npc") + unit(c(-1, -1, 1, 1), "mm"),
            y=unit(y, "npc") + unit(c(-1, 1, 1, -1), "mm"),
            hjust=c(1, 1, 0, 0),
xplineTest <- function(s, i, j, open) {
  pushViewport(viewport(layout.pos.col=j, layout.pos.row=i))
  grid.points(x, y, default.units="npc", pch=16, size=unit(2, "mm"))
  grid.xspline(x, y, shape=s, open=open, gp=gpar(fill="grey"))
  grid.text(s, gp=gpar(col="grey"),
            x=unit(x, "npc") + unit(c(-1, -1, 1, 1), "mm"),
            y=unit(y, "npc") + unit(c(-1, 1, 1, -1), "mm"),
            hjust=c(1, 1, 0, 0),
```
grid.yaxis

Draw a Y-Axis

Description

These functions create and draw a y-axis.

Usage

grid.yaxis(at = NULL, label = TRUE, main = TRUE, edits = NULL, name = NULL, gp = gpar(), draw = TRUE, vp = NULL)

yaxisGrob(at = NULL, label = TRUE, main = TRUE, edits = NULL, name = NULL, gp = gpar(), vp = NULL)
Arguments

at A numeric vector of y-value locations for the tick marks.

label A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.

main A logical value indicating whether to draw the axis at the left (TRUE) or at the right (FALSE) of the viewport.

edits A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.

name A character identifier.

gp An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.

draw A logical value indicating whether graphics output should be produced.

vp A Grid viewport object (or NULL).

Details

Both functions create a yaxis grob (a graphical object describing a yaxis), but only grid.yaxis draws the yaxis (and then only if draw is TRUE).

Value

A yaxis grob. grid.yaxis returns the value invisibly.

Children

If the at slot of an xaxis grob is not NULL then the xaxis will have the following children:

major representing the line at the base of the tick marks.

ticks representing the tick marks.

labels representing the tick labels.

If the at slot is NULL then there are no children and ticks are drawn based on the current viewport scale.

grobName  
*Generate a Name for a Grob*

**Description**

This function generates a unique (within-session) name for a grob, based on the grob’s class.

**Usage**

```r
grobName(grob = NULL, prefix = "GRID")
```

**Arguments**

- `grob`: A grob object or `NULL`.
- `prefix`: The prefix part of the name.

**Value**

A character string of the form `prefix.class(grob).index`

**Author(s)**

Paul Murrell

---

grobWidth  
*Create a Unit Describing the Width of a Grob*

**Description**

These functions create a unit object describing the width or height of a grob. They are generic.

**Usage**

```r
grobWidth(x)  
grobHeight(x)  
grobAscent(x)  
grobDescent(x)
```

**Arguments**

- `x`: A grob object.

**Value**

A unit object.

unit and stringWidth

---

**grobX**

Create a Unit Describing a Grob Boundary Location

**Description**

These functions create a unit object describing a location somewhere on the boundary of a grob. They are generic.

**Usage**

```r
grobX(x, theta)
grobY(x, theta)
```

**Arguments**

- `x` A grob, or gList, or gTree, or gPath.
- `theta` An angle indicating where the location is on the grob boundary. Can be one of "east", "north", "west", or "south", which correspond to angles 0, 90, 180, and 270, respectively.

**Details**

The angle is anti-clockwise with zero corresponding to a line with an origin centred between the extreme points of the shape, and pointing at 3 o'clock.

If the grob describes a single shape, the boundary value should correspond to the exact edge of the shape.

If the grob describes multiple shapes, the boundary value will either correspond to the edge of a bounding box around all of the shapes described by the grob (for multiple rectangles, circles, xsplines, or text), or to a convex hull around all vertices of all shapes described by the grob (for multiple polygons, points, lines, polylines, and segments).

Points grobs are currently a special case because the convex hull is based on the data symbol locations and does not take into account the extent of the data symbols themselves.

The extents of any arrow heads are currently not taken into account.

**Value**

A unit object.

**Author(s)**

Paul Murrell

**See Also**

unit and grobWidth
legendGrob

Constructing a Legend Grob

Description

Constructing a legend grob (in progress)

Usage

legendGrob(labels, nrow, ncol, byrow = FALSE,
  do.lines = has.lty || has.lwd, lines.first = TRUE,
  hgap = unit(1, "lines"), vgap = unit(1, "lines"),
  default.units = "lines", pch, gp = gpar(), vp = NULL)

grid.legend(..., draw=TRUE)

Arguments

labels
  legend labels (expressions)

nrow, ncol
  integer; the number of rows or columns, respectively of the legend “layout”.
  nrow is optional and typically computed from the number of labels and ncol.

byrow
  logical indicating whether rows of the legend are filled first.

do.lines
  logical indicating whether legend lines are drawn.

lines.first
  logical indicating whether legend lines are drawn first and hence in a plain “be-
  low” legend symbols.

hgap
  horizontal space between the legend entries

vgap
  vertical space between the legend entries

default.units
  default units, see unit.

pch
  legend symbol, numeric or character, passed to pointsGrob(); see also points
  for interpretation of the numeric codes.

gp
  an R object of class gpar, typically the output from a call to the function gpar,
  is basically a list of graphical parameter settings.

vp
  a Grid viewport object (or NULL).

...  for grid.legend(): all the arguments above are passed to legendGrob().

draw
  logical indicating whether graphics output should be produced.

Value

Both functions create a legend grob (a graphical object describing a plot legend), but only
grid.legend draws it (only if draw is TRUE).

See Also

Grid, viewport; pointsGrob, linesGrob.
grid.plot.and.legend contains a simple example.
Examples

```r
## Data:
 n <- 10
 x <- stats::runif(n); y1 <- stats::runif(n); y2 <- stats::runif(n)
## Construct the grobs:
plot <- gTree(children=gList(rectGrob(),
  pointsGrob(x, y1, pch=21, gp=gpar(col=2, fill="gray")),
  pointsGrob(x, y2, pch=22, gp=gpar(col=3, fill="gray")),
  xaxisGrob(),
  yaxisGrob()))
legd <- legendGrob(c("Girls", "Boys", "Other"), pch=21:23,
  gp=gpar(col = 2:4, fill = "gray"))
gg <- packGrob(packGrob(frameGrob(), plot),
  legd, height=unit(1,"null", side="right")
## Now draw it on a new device page:
grid.newpage()
pushViewport(viewport(width=0.8, height=0.8))
grid.draw(gg)
```

makeContent

<table>
<thead>
<tr>
<th>Customised grid Grobs</th>
</tr>
</thead>
</table>

Description

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing context and drawing content of a new class derived from grob (or gTree).

Usage

```r
makeContext(x)
makeContent(x)
```

Arguments

- **x**: A grid grob.

Details

These functions are called by the `grid.draw` methods for grobs and gTrees.

`makeContext` is called first during the drawing of a grob. This function should be used to modify the `vp` slot of `x` (and/or the `childrenvp` slot if `x` is a gTree). The function must return the modified `x`. Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for gTrees is to also push and up any viewports in the `childrenvp` slot, so this function is used to customise the drawing context for a grob or gTree.

`makeContent` is called next and is where any additional calculations should occur and graphical content should be generated (see, for example, `grid:::makeContent.xaxis`). This function should be used to modify the children of a gTree. The function must return the modified `x`. Note that the default behaviour for gTrees is to draw all grobs in the `children` slot, so this function is used to customise the drawing content for a gTree. It is also possible to customise the drawing content for
plotViewport

Create a Viewport with a Standard Plot Layout

Description
This is a convenience function for producing a viewport with the common S-style plot layout – i.e., a central plot region surrounded by margins given in terms of a number of lines of text.

Usage
plotViewport(margins=c(5.1, 4.1, 4.1, 2.1), ...)

Arguments
margins A numeric vector interpreted in the same way as par(mar) in base graphics.
...
All other arguments will be passed to a call to the viewport() function.

Value
A grid viewport object.

Author(s)
Paul Murrell

See Also
viewport and dataViewport.
Querying the Viewport Tree

Get the Current Grid Viewport (Tree)

Description

current.viewport() returns the viewport that Grid is going to draw into.
current.parent returns the parent of the current viewport.
current.vpTree returns the entire Grid viewport tree.
current.vpPath returns the viewport path to the current viewport.
current.transform returns the transformation matrix for the current viewport.
current.rotation returns the (total) rotation for the current viewport.

Usage

current.viewport()
current.parent(n=1)
current.vpTree(all=TRUE)
current.vpPath()
current.transform()

Arguments

n The number of generations to go up.
all A logical value indicating whether the entire viewport tree should be returned.

Details

It is possible to get the grandparent of the current viewport (or higher) using the n argument to current.parent().

The parent of the ROOT viewport is NULL. It is an error to request the grandparent of the ROOT viewport.

If all is FALSE then current.vpTree only returns the subtree below the current viewport.

Value

A Grid viewport object from current.viewport or current.vpTree.
current.transform returns a 4x4 transformation matrix.

The viewport path returned by current.vpPath is NULL if the current viewport is the ROOT viewport

---

resolveRasterSize  Utility function to resolve the size of a raster grob

Description

Determine the width and height of a raster grob when one or both are not given explicitly.
The result depends on both the aspect ratio of the raster image and the aspect ratio of the physical
drawing context, so the result is only valid for the drawing context in which this function is called.

Usage

resolveRasterSize(x)

Arguments

x  A raster grob

Details

A raster grob can be specified with width and/or height of NULL, which means that the size at which
the raster is drawn will be decided at drawing time.

Value

A raster grob, with explicit width and height.

See Also

gird.raster
Examples

# Square raster
rg <- rasterGrob(matrix(0))
# Fill the complete page (if page is square)
grid.newpage()
resolveRasterSize(rg)$height
grid.draw(rg)
# Forced to fit tall thin region
grid.newpage()
pushViewport(viewport(width=.1))
resolveRasterSize(rg)$height
grid.draw(rg)

roundrect

Draw a rectangle with rounded corners

Description

Draw a single rectangle with rounded corners.

Usage

roundrectGrob(x=0.5, y=0.5, width=1, height=1, default.units="npc", r=unit(0.1, "snpc"), just="centre", name=NULL, gp=NULL, vp=NULL)
grid.roundrect(...)  

Arguments

x, y, width, height
The location and size of the rectangle.
default.units A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
r The radius of the rounded corners.
just The justification of the rectangle relative to its location.
name A name to identify the grob.
gp Graphical parameters to apply to the grob.
vp A viewport object or NULL.
... Arguments to be passed to roundrectGrob().

Details

At present, this function can only be used to draw one rounded rectangle.
Examples

```r
grid.roundrect(width=.5, height=.5, name="rr")
theta <- seq(0, 360, length=50)
for (i in 1:50)
  grid.circle(x=grobX("rr", theta[i]),
              y=grobY("rr", theta[i]),
              r=unit(1, "mm"),
              gp=gpar(fill="black"))
```

showGrob  
Label grid grobs.

Description

Produces a graphical display of (by default) the current grid scene, with labels showing the names of each grob in the scene. It is also possible to label only specific grobs in the scene.

Usage

```r
showGrob(x = NULL,
          gPath = NULL, strict = FALSE, grep = FALSE,
          recurse = TRUE, depth = NULL,
          labelfun = grobLabel, ...)
```

Arguments

- **x**  
  If NULL, the current grid scene is labelled. Otherwise, a grob (or gTree) to draw and then label.

- **gPath**  
  A path identifying a subset of the current scene or grob to be labelled.

- **strict**  
  Logical indicating whether the gPath is strict.

- **grep**  
  Logical indicating whether the gPath is a regular expression.

- **recurse**  
  Should the children of gTrees also be labelled?

- **depth**  
  Only display grobs at the specified depth (may be a vector of depths).

- **labelfun**  
  Function used to generate a label from each grob.

- **...**  
  Arguments passed to `labelfun` to control fine details of the generated label.

Details

None of the labelling is recorded on the grid display list so the original scene can be reproduced by calling `grid.refresh`.

showGrob(gPath="child")
showGrob(just="left", gp=gpar(col="red", cex=.5), rot=45)
showGrob(labelfun=function(grob, ...) {
    x <- grobX(grob, "west")
y <- grobY(grob, "north")
gTree(children=gList(rectGrob(x=x, y=y,
        width=stringWidth(grob$name) + unit(2, "mm"),
        height=stringHeight(grob$name) + unit(2, "mm"),
        gp=gpar(col=NA, fill=rgb(1, 0, 0, .5)),
        just=c("left", "top")),
        textGrob(grob$name,
        x=x + unit(1, "mm"), y=y - unit(1, "mm"),
        just=c("left", "top"))))
})

## Not run:
# Examples from higher-level packages

library(lattice)
# Ctrl-c after first example
eexample(histogram)
showGrob()
showGrob(gPath="plot_01.ylab")

library(ggplot2)
# Ctrl-c after first example
eexample(qplot)
showGrob()
showGrob(recurse=FALSE)
showGrob(gPath="panel-3-3")
showGrob(gPath="axis.title", grep=TRUE)
showGrob(depth=2)

## End(Not run)
Description

Produces a graphical display of (by default) the current grid viewport tree. It is also possible to display only specific viewports. Each viewport is drawn as a rectangle and the leaf viewports are labelled with the viewport name.

Usage

```
showViewport(vp = NULL, recurse = TRUE, depth = NULL,
             newpage = FALSE, leaves = FALSE,
             col = rgb(0, 0, 1, 0.2), fill = rgb(0, 0, 1, 0.1),
             label = TRUE, nrow = 3, ncol = nrow)
```

Arguments

- **vp**: If NULL, the current viewport tree is displayed. Otherwise, a viewport (or vpList, or vpStack, or vpTree) or a vpPath that specifies which viewport to display.
- **recurse**: Should the children of the specified viewport also be displayed?
- **depth**: Only display viewports at the specified depth (may be a vector of depths).
- **newpage**: Start a new page for the display? Otherwise, the viewports are displayed on top of the current plot.
- **leaves**: Produce a matrix of smaller displays, with each leaf viewport in its own display.
- **col**: The colour used to draw the border of the rectangle for each viewport and to draw the label for each viewport. If a vector, then the first colour is used for the top-level viewport, the second colour is used for its children, the third colour for their children, and so on.
- **fill**: The colour used to fill each viewport. May be a vector as per col.
- **label**: Should the viewports be labelled (with the viewport name)?
- **nrow, ncol**: The number of rows and columns when leaves is TRUE. Otherwise ignored.

                      viewport(width=.5, height=.5, name="vp2"),
                      fill=rgb(1:0, 0:1, 0, .1),
                      newpage=TRUE)
```
stringWidth

Create a Unit Describing the Width and Height of a String or Math Expression

Description
These functions create a unit object describing the width or height of a string.

Usage

```
stringWidth(string)
stringHeight(string)
stringAscent(string)
stringDescent(string)
```

Arguments

```
string
```
A character vector or a language object (as used for ‘plotmath’ calls.

Value

A `unit` object.

Author(s)

Paul Murrell

See Also

```
unit and grobWidth
strwidth in the graphics package for more details of the typographic concepts behind the computations.
```

unit

Function to Create a Unit Object

Description

This function creates a unit object — a vector of unit values. A unit value is typically just a single numeric value with an associated unit.

Usage

```
unit(x, units, data=NULL)
```

Arguments

```
x
units
data
```
A numeric vector.
A character vector specifying the units for the corresponding numeric values.
This argument is used to supply extra information for special unit types.
Details

Unit objects allow the user to specify locations and dimensions in a large number of different coordinate systems. All drawing occurs relative to a viewport and the `units` specifies what coordinate system to use within that viewport.

Possible units (coordinate systems) are:

- **"npc"** Normalised Parent Coordinates (the default). The origin of the viewport is (0, 0) and the viewport has a width and height of 1 unit. For example, (0.5, 0.5) is the centre of the viewport.
- **"cm"** Centimetres.
- **"inches"** Inches. 1 in = 2.54 cm.
- **"mm"** Millimetres. 10 mm = 1 cm.
- **"points"** Points. 72.27 pt = 1 in.
- **"picas"** Picas. 1 pc = 12 pt.
- **"bigpts"** Big Points. 72 bp = 1 in.
- **"dida"** Dida. 1157 dd = 1238 pt.
- **"cicero"** Cicero. 1 cc = 12 dd.
- **"scaledpts"** Scaled Points. 65536 sp = 1 pt.
- **"lines"** Lines of text. Locations and dimensions are in terms of multiples of the default text size of the viewport (as specified by the viewport's `fontsize` and `lineheight`).
- **"char"** Multiples of nominal font height of the viewport (as specified by the viewport's `fontsize`).
- **"native"** Locations and dimensions are relative to the viewport's `xscale` and `yscale`.
- **"snpc"** Square Normalised Parent Coordinates. Same as Normalised Parent Coordinates, except gives the same answer for horizontal and vertical locations/dimensions. It uses the lesser of npc-width and npc-height. This is useful for making things which are a proportion of the viewport, but have to be square (or have a fixed aspect ratio).
- **"strwidth"** Multiples of the width of the string specified in the `data` argument. The font size is determined by the `pointsize` of the viewport.
- **"strheight"** Multiples of the height of the string specified in the `data` argument. The font size is determined by the `pointsize` of the viewport.
- **"grobwidth"** Multiples of the width of the grob specified in the `data` argument.
- **"grobheight"** Multiples of the height of the grob specified in the `data` argument.

A number of variations are also allowed for the most common units. For example, it is possible to use "in" or "inch" instead of "inches" and "centimetre" or "centimeter" instead of "cm".

A special units value of "null" is also allowed, but only makes sense when used in specifying widths of columns or heights of rows in grid layouts (see `grid.layout`).

The `data` argument must be a list when the `unit.length()` is greater than 1. For example,

```r
unit(rep(1, 3), c("npc", "strwidth", "inches"),
     data = list(NULL, "my string", NULL))
```

It is possible to subset unit objects in the normal way and to perform subassignment (see the examples), but a special function `unit.c` is provided for combining unit objects.

Certain arithmetic and summary operations are defined for unit objects. In particular, it is possible to add and subtract unit objects (e.g., `unit(1, "npc") - unit(1, "inches")`),
and to specify the minimum or maximum of a list of unit objects (e.g.,
\[ \text{min}(\text{unit}(0.5, \text{"npc"}), \text{unit}(1, \text{"inches"})). \]

There is a format method for units, which should respond to the arguments for the default format
method, e.g., digits to control the number of significant digits printed for numeric values.

**Value**

An object of class "unit".

**WARNING**

There is a special function `unit.c` for concatenating several unit objects.

The `c` function will not give the right answer.

There used to be "mylines", "mychar", "mystrwidth", "mystrheight" units. These will still be
accepted, but work exactly the same as "lines", "char", "strwidth", "strheight".

**Author(s)**

Paul Murrell

**See Also**

`unit.c`

**Examples**

```r
unit(1, "npc")
unit(1:3/4, "npc")
unit(1:3/4, "npc") + unit(1, "inches")
min(unit(0.5, "npc"), unit(1, "inches"))
unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
       unit(1, "strwidth", "hi there"))
x <- unit(1:5, "npc")
x[2:4]
x[2:4] <- unit(1, "mm")
x
```

---

**Description**

This function produces a new unit object by combining the unit objects specified as arguments.

**Usage**

```r
unit.c(...)```

**Arguments**

... An arbitrary number of unit objects.
Value

An object of class unit.

Author(s)

Paul Murrell

See Also

unit

unit.length  
Length of a Unit Object

Description

The length of a unit object is defined as the number of unit values in the unit object.

This function has been deprecated in favour of a unit method for the generic length function.

Usage

unit.length(unit)

Arguments

unit  
A unit object.

Value

An integer value.

Author(s)

Paul Murrell

See Also

unit

Examples

length(unit(1:3, "npc"))
length(unit(1:3, "npc") + unit(1, "inches"))
length(max(unit(1:3, "npc") + unit(1, "inches")))
length(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4)
length(unit(1:3, "npc") + unit(1, "strwidth", "a")*4)
**unit.pmin**

**Parallel Unit Minima and Maxima**

**Description**

Returns a unit object whose i’th value is the minimum (or maximum) of the i’th values of the arguments.

**Usage**

```r
unit.pmin(...)  
unit.pmax(...)  
```

**Arguments**

```r
... One or more unit objects.  
```

**Details**

The length of the result is the maximum of the lengths of the arguments; shorter arguments are recycled in the usual manner.

**Value**

A unit object.

**Author(s)**

Paul Murrell

**Examples**

```r
max(unit(1:3, "cm"), unit(0.5, "npc"))  
unit.pmax(unit(1:3, "cm"), unit(0.5, "npc"))  
```

---

**unit.rep**

**Replicate Elements of Unit Objects**

**Description**

Replicates the units according to the values given in `times` and `length.out`.

This function has been deprecated in favour of a unit method for the generic `rep` function.

**Usage**

```r
unit.rep(x, ...)  
```

**Arguments**

```r
x An object of class "unit".  
... arguments to be passed to `rep` such as `times` and `length.out`.  
```
Valid.just

Value

An object of class "unit".

rep(unit(1:3, "npc"), 1:3)
rep(unit(1:3, "npc") + unit(1, "inches"), 3)
rep(max(unit(1:3, "npc") + unit(1, "inches")), 3)
rep(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)
rep(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)

valid.just  Validate a Justification

Description

Utility functions for determining whether a justification specification is valid and for resolving a single justification value from a combination of character and numeric values.

Usage

valid.just(just)
resolveHJust(just, hjust)
resolveVJust(just, vjust)

Arguments

just A justification either as a character value, e.g., "left", or as a numeric value, e.g., 0.
hjust A numeric horizontal justification
vjust A numeric vertical justification

Details

These functions may be useful within a validDetails method when writing a new grob class.

Value

A numeric representation of the justification (e.g., "left" becomes 0, "right" becomes 1, etc,...). An error is given if the justification is not valid.

Author(s)

Paul Murrell
validDetails

Customising grid grob Validation

Description
This generic hook function is called whenever a grid grob is created or edited via `grob`, `gTree`, `grid.edit` or `editGrob`. This provides an opportunity for customising the validation of a new class derived from `grob` (or `gTree`).

Usage
validDetails(x)

Arguments
x
A grid grob.

Details
This function is called by `grob`, `gTree`, `grid.edit` and `editGrob`. A method should be written for classes derived from `grob` or `gTree` to validate the values of slots specific to the new class. (e.g., see `grid:::validDetails.axis`).

Note that the standard slots for `grob`s and `gTree`s are automatically validated (e.g., `vp`, `gp` slots for `grob`s and, in addition, `children`, and `childrenvp` slots for `gTree`s) so only slots specific to a new class need to be addressed.

Value
The function MUST return the validated grob.

Author(s)
Paul Murrell

See Also
`grid.edit`

vpPath

Concatenate Viewport Names

Description
This function can be used to generate a viewport path for use in `downViewport` or `seekViewport`. A viewport path is a list of nested viewport names.

Usage
vpPath(...)
widthDetails

Arguments

... Character values which are viewport names.

Details

Viewport names must only be unique amongst viewports which share the same parent in the viewport tree.

This function can be used to generate a specification for a viewport that includes the viewport’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value

A vpPath object.

See Also

viewport, pushViewport, popViewport, downViewport, seekViewport, upViewport

Examples

vpPath("vp1", "vp2")

widthDetails Width and Height of a grid grob

Description

These generic functions are used to determine the size of grid grobs.

Usage

widthDetails(x)
heightDetails(x)
ascentDetails(x)
descentDetails(x)

Arguments

x A grid grob.

Details

These functions are called in the calculation of "grobwidth" and "grobheight" units. Methods should be written for classes derived from grob or gTree where the size of the grob can be determined (see, for example grid:::widthDetails.frame).

The ascent of a grob is the height of the grob by default and the descent of a grob is zero by default, except for text grobs where the label is a single character value or expression.
Working with Viewports

Value
A unit object.

Author(s)
Paul Murrell

See Also
absolute.size.

Description
Grid maintains a tree of viewports — nested drawing contexts.
These functions provide ways to add or remove viewports and to navigate amongst viewports in the tree.

Usage
pushViewport(..., recording=TRUE)
popViewport(n = 1, recording=TRUE)
downViewport(name, strict=FALSE, recording=TRUE)
seekViewport(name, recording=TRUE)
upViewport(n = 1, recording=TRUE)

Arguments
...
One or more objects of class "viewport".
n
An integer value indicating how many viewports to pop or navigate up. The special value 0 indicates to pop or navigate viewports right up to the root viewport.
name
A character value to identify a viewport in the tree.
strict
A boolean indicating whether the vpPath must be matched exactly.
recording
A logical value to indicate whether the viewport operation should be recorded on the Grid display list.

Details
Objects created by the viewport() function are only descriptions of a drawing context. A viewport object must be pushed onto the viewport tree before it has any effect on drawing.
The viewport tree always has a single root viewport (created by the system) which corresponds to the entire device (and default graphical parameter settings). Viewports may be added to the tree using pushViewport() and removed from the tree using popViewport().
There is only ever one current viewport, which is the current position within the viewport tree. All drawing and viewport operations are relative to the current viewport. When a viewport is pushed it becomes the current viewport. When a viewport is popped, the parent viewport becomes the current
viewport. Use `upViewport` to navigate to the parent of the current viewport, without removing the current viewport from the viewport tree. Use `downViewport` to navigate to a viewport further down the viewport tree and `seekViewport` to navigate to a viewport anywhere else in the tree.

If a viewport is pushed and it has the same name as a viewport at the same level in the tree, then it replaces the existing viewport in the tree.

**Value**

`downViewport` returns the number of viewports it went down.

This can be useful for returning to your starting point by doing something like `depth <- downViewport()` then `upViewport(depth)`.

**Examples**

```r
# push the same viewport several times
grid.newpage()
vp <- viewport(width=0.5, height=0.5)
pushViewport(vp)
grid.rect(gp=gpar(col="blue"))
grid.text("Quarter of the device",
y=unit(1, "npc") - unit(1, "lines"), gp=gpar(col="blue"))
pushViewport(vp)
grid.rect(gp=gpar(col="red"))
grid.text("Quarter of the parent viewport",
y=unit(1, "npc") - unit(1, "lines"), gp=gpar(col="red"))
popViewport(2)
# push several viewports then navigate amongst them
grid.newpage()
grid.rect(gp=gpar(col="grey"))
grid.text("Top-level viewport",
y=unit(1, "npc") - unit(1, "lines"), gp=gpar(col="grey"))
if (interactive()) Sys.sleep(1.0)
pushViewport(viewport(width=0.8, height=0.7, name="A"))
grid.rect(gp=gpar(col="blue"))
grid.text("1. Push Viewport A",
y=unit(1, "npc") - unit(1, "lines"), gp=gpar(col="blue"))
if (interactive()) Sys.sleep(1.0)
pushViewport(viewport(x=0.1, width=0.3, height=0.6, just="left", name="B"))
grid.rect(gp=gpar(col="red"))
grid.text("2. Push Viewport B (in A)",
y=unit(1, "npc") - unit(1, "lines"), gp=gpar(col="red"))
if (interactive()) Sys.sleep(1.0)
popViewport(1)
grid.text("3. Up from B to A",
y=unit(1, "npc") - unit(2, "lines"), gp=gpar(col="blue"))
if (interactive()) Sys.sleep(1.0)
pushViewport(viewport(x=0.5, width=0.4, height=0.8, just="left", name="C"))
grid.rect(gp=gpar(col="black"))
grid.text("3. Up from B to A",
y=unit(1, "npc") - unit(2, "lines"), gp=gpar(col="black"))
if (interactive()) Sys.sleep(1.0)
popViewport(2)
```

4. Push Viewport C (in A)
   grid.rect(gp=gpar(col="green"),
   y=unit(1, "npc") - unit(1, "lines"), gp=gpar(col="green"))
if (interactive()) Sys.sleep(1)
pushViewport(viewport(width=0.8, height=0.6, name="D"))
grid.rect()
grid.text("5. Push Viewport D (in C)",
   y=unit(1, "npc") - unit(1, "lines"))
if (interactive()) Sys.sleep(1)
upViewport(0)
grid.text("6. Up from D to top-level",
   y=unit(1, "npc") - unit(2, "lines"), gp=gpar(col="grey"))
if (interactive()) Sys.sleep(1)
downViewport("D")
grid.text("7. Down from top-level to D",
   y=unit(1, "npc") - unit(2, "lines"))
if (interactive()) Sys.sleep(1)
seekViewport("B")
grid.text("8. Seek from D to B",
   y=unit(1, "npc") - unit(2, "lines"), gp=gpar(col="red"))
pushViewport(viewport(width=0.9, height=0.5, name="A"))
grid.rect()
grid.text("9. Push Viewport A (in B)",
   y=unit(1, "npc") - unit(1, "lines"))
if (interactive()) Sys.sleep(1)
seekViewport("A")
grid.text("10. Seek from B to A (in ROOT)",
   y=unit(1, "npc") - unit(3, "lines"), gp=gpar(col="blue"))
if (interactive()) Sys.sleep(1)
seekViewport(vpPath("B", "A"))
grid.text("11. Seek from A (in ROOT)\nto A (in B)"
popViewport(0)

**xDetails**

**Boundary of a grid grob**

**Description**

These generic functions are used to determine a location on the boundary of a grid grob.

**Usage**

xDetails(x, theta)
yDetails(x, theta)

**Arguments**

- **x**
  A grid grob.

- **theta**
  A numeric angle, in degrees, measured anti-clockwise from the 3 o’clock or one of the following character strings: "north", "east", "west", "south".
Details

The location on the grob boundary is determined by taking a line from the centre of the grob at the angle \( \theta \) and intersecting it with the convex hull of the grob (for the basic grob primitives, the centre is determined as half way between the minimum and maximum values in x and y directions). These functions are called in the calculation of "grobx" and "groby" units as produced by the grobX and grobY functions. Methods should be written for classes derived from grob or gTree where the boundary of the grob can be determined.

Value

A unit object.

Author(s)

Paul Murrell

See Also

grobX, grobY.

---

**xsplinePoints**

Return the points that would be used to draw an Xspline (or a Bezier curve).

Description

Rather than drawing an Xspline (or Bezier curve), this function returns the points that would be used to draw the series of line segments for the Xspline. This may be useful to post-process the Xspline curve, for example, to clip the curve.

Usage

xsplinePoints(x)
bezierPoints(x)

Arguments

x

An Xspline grob, as produced by the xsplineGrob() function (or a beziergrob, as produced by the bezierGrob() function).

Details

The points returned by this function will only be relevant for the drawing context in force when this function was called.

Value

Depends on how many Xsplines would be drawn. If only one, then a list with two components, named x and y, both of which are unit objects (in inches). If several Xsplines would be drawn then the result of this function is a list of lists.

Examples

grid.newpage()
xsg <- xsplineGrob(c(.1, .1, .9, .9), c(.1, .9, .9, .1), shape=1)
grid.draw(xsg)
trace <- xsplinePoints(xsg)
grid.circle(trace$x, trace$y, default.units="inches", r=unit(.5, "mm"))

grid.newpage()
vp <- viewport(width=.5)
xg <- xsplineGrob(x=c(0, .2, .4, .2, .5, .7, .9, .7),
                   y=c(.5, 1, .5, 0, .5, 1, .5, 0),
                   id=rep(1:2, each=4),
                   shape=1,
                   vp=vp)
grid.draw(xg)
trace <- xsplinePoints(xg)
pushViewport(vp)
invisible(lapply(trace, function(t) grid.lines(t$x, t$y, gp=gpar(col="red"))))
popViewport()

grid.newpage()
bg <- bezierGrob(c(.2, .2, .8, .8), c(.2, .8, .8, .2))
grid.draw(bg)
trace <- bezierPoints(bg)
grid.circle(trace$x, trace$y, default.units="inches", r=unit(.5, "mm"))
Chapter 7

The methods package

Description

Formally defined methods and classes for R objects, plus other programming tools, as described in the references.

Details

This package provides the “S4” or “S version 4” approach to methods and classes in a functional language.

For basic use of the techniques, start with Introduction and follow the links there to the key functions for programming, notably setClass and setMethod.

Some specific topics:

Classes: Creating one, see setClass; examining definitions, see getClassDef and classRepresentation; inheritance and coercing, see is and as

Generic functions: Basic programming, see setGeneric; the class of objects, see genericFunction; other functions to examine or manipulate them, see GenericFunctions.

S3: Using classes, see setOldClass; methods, see Methods_for_S3.

Reference classes: See ReferenceClasses.

Class unions; virtual classes See setClassUnion.

These pages will have additional links to related topics.

For a complete list of functions and classes, use library(help=“methods”).

`.BasicFunsList`  
*List of Builtin and Special Functions*

**Description**

A named list providing instructions for turning builtin and special functions into generic functions.

Functions in R that are defined as `.Primitive(<name>)` are not suitable for formal methods, because they lack the basic reflectance property. You can’t find the argument list for these functions by examining the function object itself.

Future versions of R may fix this by attaching a formal argument list to the corresponding function. While generally the names of arguments are not checked by the internal code implementing the function, the number of arguments frequently is.

In any case, some definition of a formal argument list is needed if users are to define methods for these functions. In particular, if methods are to be merged from multiple packages, the different sets of methods need to agree on the formal arguments.

In the absence of reflectance, this list provides the relevant information via a dummy function associated with each of the known specials for which methods are allowed.

At the same, the list flags those specials for which methods are meaningless (e.g., `for`) or just a very bad idea (e.g., `.Primitive`).

A generic function created via `setMethod`, for example, for one of these special functions will have the argument list from `.BasicFunsList`. If no entry exists, the argument list `(x, ...)` is assumed.

---

`as`  
*Force an Object to Belong to a Class*

**Description**

Coerce an object to a given class.

**Usage**

```r
as(object, Class, strict=TRUE, ext)
```

```r
as(object, Class) <- value
```
Arguments

object any R object.
Class the name of the class to which object should be coerced.
strict logical flag. If TRUE, the returned object must be strictly from the target class (unless that class is a virtual class, in which case the object will be from the closest actual class, in particular the original object, if that class extends the virtual class directly).

If strict = FALSE, any simple extension of the target class will be returned, without further change. A simple extension is, roughly, one that just adds slots to an existing class.
value The value to use to modify object (see the discussion below). You should supply an object with class Class; some coercion is done, but you’re unwise to rely on it.

ext an optional object defining how Class is extended by the class of the object (as returned by possibleExtends). This argument is used internally; do not use it directly.

Description

as(object) returns the version of this object coerced to be the given Class. When used in the replacement form on the left of an assignment, the portion of the object corresponding to Class is replaced by value.

The operation of as() in either form depends on the definition of coerce methods. Methods are defined automatically when the two classes are related by inheritance; that is, when one of the classes is a subclass of the other.

Coerce methods are also predefined for basic classes (including all the types of vectors, functions and a few others).

Beyond these two sources of methods, further methods are defined by calls to the setAs function. See that documentation also for details of how coerce methods work. Use showMethods(coerce) for a list of all currently defined methods, as in the example below.

Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, as(x, "numeric") uses the existing as.numeric function. These and all other existing methods can be listed as shown in the example.

Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

See Also

If you think of using try(as(x, cl)), consider canCoerce(x, cl) instead.

Examples

### Show all the existing methods for as()
showMethods("coerce")
Classes Corresponding to Basic Data Types

Description

Formal classes exist corresponding to the basic R object types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

Usage

### The following are all basic vector classes.
### They can appear as class names in method signatures,
### in calls to `as()`, `is()`, and `new()`.
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

### the class
"vector"
### is a virtual class, extended by all the above

### the class
"S4"
### is an object type for S4 objects that do not extend
### any of the basic vector classes. It is a virtual class.

### The following are additional basic classes
"NULL"  # NULL objects
"Function"  # function objects, including primitives
"externalptr"  # raw external pointers for use in C code

"ANY"  # virtual classes used by the methods package itself
"VIRTUAL"
"missing"

"namedList"  # the alternative to "list" that preserves
  # the names attribute

Objects from the Classes

If a class is not virtual (see section in `Classes_Details`), objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.
The class "expression" is slightly odd, in that the ... arguments will *not* be evaluated; therefore, don't enclose them in a call to quote().

Note that class "list" is a pure vector. Although lists with names go back to the earliest versions of S, they are an extension of the vector concept in that they have an attribute (which can now be a slot) and which is either NULL or a character vector of the same length as the vector. If you want to guarantee that list names are preserved, use class "namedList", rather than "list". Objects from this class must have a names attribute, corresponding to slot "names", of type "character". Internally, R treats names for lists specially, which makes it impractical to have the corresponding slot in class "namedList" be a union of character names and NULL.

Classes and Types
