Unit objects allow the user to specify locations and dimensions in a large number of different coordinate systems. All drawing occurs relative to a viewport and the units specifies what coordinate system to use within that viewport.

Possible units (coordinate systems) are:

"npc" Normalised Parent Coordinates (the default). The origin of the viewport is (0, 0) and the viewport has a width and height of 1 unit. For example, (0.5, 0.5) is the centre of the viewport.

"cm" Centimetres.

"inches" Inches. 1 in = 2.54 cm.

"mm" Millimetres. 10 mm = 1 cm.

"points" Points. 72.27 pt = 1 in.

"picas" Picas. 1 pc = 12 pt.

"bigpts" Big Points. 72 bp = 1 in.

"dida" Dida. 1157 dd = 1238 pt.

"cicero" Cicero. 1 cc = 12 dd.

"scaledpts" Scaled Points. 65536 sp = 1 pt.

"lines" Lines of text. Locations and dimensions are in terms of multiples of the default text size of the viewport (as specified by the viewport's fontsize and lineheight).

"char" Multiples of nominal font height of the viewport (as specified by the viewport's fontsize).

"native" Locations and dimensions are relative to the viewport's xscale and yscale.

"snpc" Square Normalised Parent Coordinates. Same as Normalised Parent Coordinates, except gives the same answer for horizontal and vertical locations/dimensions. It uses the lesser of npc-width and npc-height. This is useful for making things which are a proportion of the viewport, but have to be square (or have a fixed aspect ratio).

"strwidth" Multiples of the width of the string specified in the data argument. The font size is determined by the pointsize of the viewport.

"strheight" Multiples of the height of the string specified in the data argument. The font size is determined by the pointsize of the viewport.

"grobwidth" Multiples of the width of the grob specified in the data argument.

"grobheight" Multiples of the height of the grob specified in the data argument.

A number of variations are also allowed for the most common units. For example, it is possible to use "in" or "inch" instead of "inches" and "centimetre" or "centimeter" instead of "cm". A special units value of "null" is also allowed, but only makes sense when used in specifying widths of columns or heights of rows in grid layouts (see grid.layout).

The data argument must be a list when the unit.length() is greater than 1. For example,

```r
unit(rep(1, 3), c("npc", "strwidth", "inches"),
data = list(NULL, "my string", NULL))
```

It is possible to subset unit objects in the normal way and to perform subassignment (see the examples), but a special function unit.c is provided for combining unit objects.

Certain arithmetic and summary operations are defined for unit objects. In particular, it is possible to add and subtract unit objects (e.g., unit(1, "npc") - unit(1, "inches")),
and to specify the minimum or maximum of a list of unit objects (e.g.,
\texttt{min(unit(0.5, "npc"), unit(1, "inches"))}).

There is a format method for units, which should respond to the arguments for the default format
method, e.g., \texttt{digits} to control the number of significant digits printed for numeric values.

\section*{Value}
An object of class "unit".

\section*{WARNING}
There is a special function \texttt{unit.c} for concatenating several unit objects.
The \texttt{c} function will not give the right answer.

There used to be "mylines", "mychar", "mystrwidth", "mystrheight" units. These will still be
accepted, but work exactly the same as "lines", "char", "strwidth", "strheight".

\section*{Author(s)}
Paul Murrell

\section*{See Also}
\texttt{unit.c}

\section*{Examples}
\begin{verbatim}
unit(1, "npc")
unit(1:3/4, "npc")
unit(1:3/4, "npc") + unit(1, "inches")
min(unit(0.5, "npc"), unit(1, "inches"))
unit.c(unit(0.5, "npc"), unit(1, "inches") + unit(1:3/4, "npc"),
       unit(1, "strwidth", "hi there"))
x <- unit(1:5, "npc")
x[2:4]
x[2:4] <- unit(1, "mm")
x
\end{verbatim}

\section*{Description}
This function produces a new unit object by combining the unit objects specified as arguments.

\section*{Usage}
\texttt{unit.c(...)}

\section*{Arguments}
\begin{verbatim}
... An arbitrary number of unit objects.
\end{verbatim}
Value
An object of class unit.

**unit.length**

*Length of a Unit Object*

**Description**
The length of a unit object is defined as the number of unit values in the unit object.
This function has been deprecated in favour of a unit method for the generic `length` function.

**Usage**

`unit.length(unit)`

**Arguments**

- `unit` A unit object.

**Value**
An integer value.

**Author(s)**
Paul Murrell

**See Also**

unit

**Examples**

```r
length(unit(1:3, "npc"))
length(unit(1:3, "npc") + unit(1, "inches"))
length(max(unit(1:3, "npc") + unit(1, "inches")))
length(max(unit(1:3, "npc") + unit(1, "strwidth", "a")*4))
length(unit(1:3, "npc") + unit(1, "strwidth", "a")*4)
```
unit.pmin

**Parallel Unit Minima and Maxima**

**Description**

Returns a unit object whose i’th value is the minimum (or maximum) of the i’th values of the arguments.

**Usage**

```
unit.pmin(...)  
unit.pmax(...)  
```

**Arguments**

... One or more unit objects.

**Details**

The length of the result is the maximum of the lengths of the arguments; shorter arguments are recycled in the usual manner.

**Value**

A unit object.

**Author(s)**

Paul Murrell

**Examples**

```
max(unit(1:3, "cm"), unit(0.5, "npc"))  
unit.pmax(unit(1:3, "cm"), unit(0.5, "npc"))  
```

---

unit.rep

**Replicate Elements of Unit Objects**

**Description**

Replicates the units according to the values given in times and length.out.

This function has been deprecated in favour of a unit method for the generic `rep` function.

**Usage**

```
unit.rep(x, ...)  
```

**Arguments**

`x` An object of class "unit".

... arguments to be passed to `rep` such as times and length.out.
Valid.just

Description
Utility functions for determining whether a justification specification is valid and for resolving a single justification value from a combination of character and numeric values.

Usage
valid.just(just)
resolveHJust(just, hjust)
resolveVJust(just, vjust)

Arguments
just A justification either as a character value, e.g., "left", or as a numeric value, e.g., 0.
hjust A numeric horizontal justification
vjust A numeric vertical justification

Details
These functions may be useful within a validDetails method when writing a new grob class.

Value
A numeric representation of the justification (e.g., "left" becomes 0, "right" becomes 1, etc, ...). An error is given if the justification is not valid.

Author(s)
Paul Murrell
validDetails

Customising grid grob Validation

Description

This generic hook function is called whenever a grid grob is created or edited via grob, gTree, grid.edit or editGrob. This provides an opportunity for customising the validation of a new class derived from grob (or gTree).

Usage

validDetails(x)

Arguments

x

A grid grob.

Details

This function is called by grob, gTree, grid.edit and editGrob. A method should be written for classes derived from grob or gTree to validate the values of slots specific to the new class. (e.g., see grid:::validDetails.axis).

Note that the standard slots for grobs and gTrees are automatically validated (e.g., vp, gp slots for grobs and, in addition, children, and childrenvp slots for gTrees) so only slots specific to a new class need to be addressed.

Value

The function MUST return the validated grob.

Author(s)

Paul Murrell

See Also

grid.edit

vpPath

Concatenate Viewport Names

Description

This function can be used to generate a viewport path for use in downViewport or seekViewport. A viewport path is a list of nested viewport names.

Usage

vpPath(…)

Arguments

Character values which are viewport names.

Details

Viewport names must only be unique amongst viewports which share the same parent in the viewport tree.

This function can be used to generate a specification for a viewport that includes the viewport’s parent’s name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value

A vpPath object.

See Also

viewport, pushViewport, popViewport, downViewport, seekViewport, upViewport

Examples

vpPath("vp1", "vp2")

widthDetails

Width and Height of a grid grob

Description

These generic functions are used to determine the size of grid grobs.

Usage

widthDetails(x)
heightDetails(x)
ascentDetails(x)
descentDetails(x)

Arguments

x A grid grob.

Details

These functions are called in the calculation of "grobwidth" and "grobheight" units. Methods should be written for classes derived from grob or gTree where the size of the grob can be determined (see, for example grid:::widthDetails.frame).

The ascent of a grob is the height of the grob by default and the descent of a grob is zero by default, except for text grobs where the label is a single character value or expression.
Working with Viewports

Value

A unit object.

absolute.size.

Maintaining and Navigating the Grid Viewport Tree

Description

Grid maintains a tree of viewports — nested drawing contexts. These functions provide ways to add or remove viewports and to navigate amongst viewports in the tree.

Usage

pushViewport(..., recording=TRUE)
popViewport(n = 1, recording=TRUE)
downViewport(name, strict=FALSE, recording=TRUE)
seekViewport(name, recording=TRUE)
upViewport(n = 1, recording=TRUE)

Arguments

... One or more objects of class "viewport".

n An integer value indicating how many viewports to pop or navigate up. The special value 0 indicates to pop or navigate viewports right up to the root viewport.

name A character value to identify a viewport in the tree.

strict A boolean indicating whether the vpPath must be matched exactly.

recording A logical value to indicate whether the viewport operation should be recorded on the Grid display list.

Details

Objects created by the viewport() function are only descriptions of a drawing context. A viewport object must be pushed onto the viewport tree before it has any effect on drawing.

The viewport tree always has a single root viewport (created by the system) which corresponds to the entire device (and default graphical parameter settings). Viewports may be added to the tree using pushViewport() and removed from the tree using popViewport().

There is only ever one current viewport, which is the current position within the viewport tree. All drawing and viewport operations are relative to the current viewport. When a viewport is pushed it becomes the current viewport. When a viewport is popped, the parent viewport becomes the current...
viewport. Use `upViewport` to navigate to the parent of the current viewport, without removing the current viewport from the viewport tree. Use `downViewport` to navigate to a viewport further down the viewport tree and `seekViewport` to navigate to a viewport anywhere else in the tree.

If a viewport is pushed and it has the same name as a viewport at the same level in the tree, then it replaces the existing viewport in the tree.

**Value**

downViewport returns the number of viewports it went down.

This can be useful for returning to your starting point by doing something like `depth <- downViewport()` then `upViewport(depth)`.

**Author(s)**

Paul Murrell

pushViewport(viewport(width=0.9, height=0.5, name="A"))
g电网.rect()
g电网.text("9. Push Viewport A (in B)",
y=unit(1, "npc") - unit(1, "lines"))
if (interactive()) Sys.sleep(1.0)
seekViewport("A")
g电网.text("10. Seek from B to A (in ROOT)",
y=unit(1, "npc") - unit(3, "lines"), gp=gpar(col="blue"))
if (interactive()) Sys.sleep(1.0)
seekViewport(vpPath("B", "A"))
g电网.text("11. Seek from\nA (in ROOT)\nto A (in B)"
popViewport(0)

xDetails | Boundary of a grid grob

Description
These generic functions are used to determine a location on the boundary of a grid grob.

Usage

xDetails(x, theta)
yDetails(x, theta)

Arguments

x A grid grob.
theta A numeric angle, in degrees, measured anti-clockwise from the 3 o’clock or one of the following character strings: "north", "east", "west", "south".
Details

The location on the grob boundary is determined by taking a line from the centre of the grob at the
angle $\theta$ and intersecting it with the convex hull of the grob (for the basic grob primitives, the
centre is determined as half way between the minimum and maximum values in x and y directions).
These functions are called in the calculation of "grobx" and "groby" units as produced by the
grobX and grobY functions. Methods should be written for classes derived from grob or gTree
where the boundary of the grob can be determined.

Value

A unit object.

Author(s)

Paul Murrell

See Also

grobX, grobY.

---

xsplinePoints

*Return the points that would be used to draw an Xspline (or a Bezier curve).*

Description

Rather than drawing an Xspline (or Bezier curve), this function returns the points that would be
used to draw the series of line segments for the Xspline. This may be useful to post-process the
Xspline curve, for example, to clip the curve.

Usage

xsplinePoints(x)
bezierPoints(x)

Arguments

x

An Xspline grob, as produced by the xsplineGrob() function (or a beziergrob, as produced by the bezierGrob() function).

Details

The points returned by this function will only be relevant for the drawing context in force when this
function was called.

Value

Depends on how many Xsplines would be drawn. If only one, then a list with two components,
named x and y, both of which are unit objects (in inches). If several Xsplines would be drawn then
the result of this function is a list of lists.

trace <- xsplinePoints(xsg)
grid.circle(trace$x, trace$y, default.units="inches", r=unit(.5, "mm"))

grid.newpage()
vp <- viewport(width=.5)
xg <- xsplineGrob(x=c(0, .2, .4, .2, .5, .7, .9, .7),
y=c(.5, 1, .5, 0, .5, 1, .5, 0),
   id=rep(1:2, each=4),
   shape=1,
   vp=vp)
grid.draw(xg)
trace <- xsplinePoints(xg)
pushViewport(vp)
invisible(lapply(trace, function(t) grid.lines(t$x, t$y, gp=gpar(col="red"))))
popViewport()

grid.newpage()
bg <- bezierGrob(c(.2, .2, .8, .8), c(.2, .8, .8, .2))
gird.draw(bg)
trace <- bezierPoints(bg)
grid.circle(trace$x, trace$y, default.units="inches", r=unit(.5, "mm"))
Chapter 7

The methods package

Description

Formally defined methods and classes for R objects, plus other programming tools, as described in the references.

Details

This package provides the “S4” or “S version 4” approach to methods and classes in a functional language.

For basic use of the techniques, start with Introduction and follow the links there to the key functions for programming, notably \texttt{setClass} and \texttt{setMethod}.

Some specific topics:

\textbf{Classes:} Creating one, see \texttt{setClass}; examining definitions, see \texttt{getClassDef} and \texttt{classRepresentation}; inheritance and coercing, see \texttt{is} and \texttt{as}

\textbf{Generic functions:} Basic programming, see \texttt{setGeneric}; the class of objects, see \texttt{genericFunction}; other functions to examine or manipulate them, see \texttt{GenericFunctions}.

\textbf{S3:} Using classes, see \texttt{setOldClass}; methods, see \texttt{Methods_for_S3}.

\textbf{Reference classes:} See \texttt{ReferenceClasses}.

\textbf{Class unions; virtual classes} See \texttt{setClassUnion}.

These pages will have additional links to related topics.

For a complete list of functions and classes, use \texttt{library(help="methods")}.

**BasicFunsList**  
**List of Builtin and Special Functions**

**Description**

A named list providing instructions for turning builtin and special functions into generic functions.

Functions in R that are defined as `.Primitive(<name>)` are not suitable for formal methods, because they lack the basic reflectance property. You can’t find the argument list for these functions by examining the function object itself.

Future versions of R may fix this by attaching a formal argument list to the corresponding function. While generally the names of arguments are not checked by the internal code implementing the function, the number of arguments frequently is.

In any case, some definition of a formal argument list is needed if users are to define methods for these functions. In particular, if methods are to be merged from multiple packages, the different sets of methods need to agree on the formal arguments.

In the absence of reflectance, this list provides the relevant information via a dummy function associated with each of the known specials for which methods are allowed.

At the same, the list flags those specials for which methods are meaningless (e.g., `for`) or just a very bad idea (e.g., `.Primitive`).

A generic function created via `setMethod`, for example, for one of these special functions will have the argument list from `.BasicFunsList`. If no entry exists, the argument list `(x, ...)` is assumed.

---

**as**  
**Force an Object to Belong to a Class**

**Description**

Coerce an object to a given class.

**Usage**

```r
as(object, Class, strict=TRUE, ext)
as(object, Class) <- value
```
Arguments

object any R object.
Class the name of the class to which object should be coerced.
strict logical flag. If TRUE, the returned object must be strictly from the target class (unless that class is a virtual class, in which case the object will be from the closest actual class, in particular the original object, if that class extends the virtual class directly).
If strict = FALSE, any simple extension of the target class will be returned, without further change. A simple extension is, roughly, one that just adds slots to an existing class.
value The value to use to modify object (see the discussion below). You should supply an object with class Class; some coercion is done, but you’re unwise to rely on it.
ext an optional object defining how Class is extended by the class of the object (as returned by possibleExtends). This argument is used internally; do not use it directly.

Description

as(object) returns the version of this object coerced to be the given Class. When used in the replacement form on the left of an assignment, the portion of the object corresponding to Class is replaced by value.
The operation of as() in either form depends on the definition of coerce methods. Methods are defined automatically when the two classes are related by inheritance; that is, when one of the classes is a subclass of the other.
Coerce methods are also predefined for basic classes (including all the types of vectors, functions and a few others).
Beyond these two sources of methods, further methods are defined by calls to the setAs function. See that documentation also for details of how coerce methods work. Use showMethods(coerce) for a list of all currently defined methods, as in the example below.

Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, as(x, "numeric") uses the existing as.numeric function. These and all other existing methods can be listed as shown in the example.

References

Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

See Also

If you think of using try(as(x, cl)), consider canCoerce(x, cl) instead.

Examples

## Show all the existing methods for as()
showMethods("coerce")
Classes Corresponding to Basic Data Types

Description

Formal classes exist corresponding to the basic R object types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

Usage

```
### The following are all basic vector classes.
### They can appear as class names in method signatures,
### in calls to as(), is(), and new().
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

### the class
"vector"
### is a virtual class, extended by all the above

### the class
"S4"
### is an object type for S4 objects that do not extend
### any of the basic vector classes. It is a virtual class.

### The following are additional basic classes
"NULL" # NULL objects
"Function" # function objects, including primitives
"externalptr" # raw external pointers for use in C code

"ANY" # virtual classes used by the methods package itself
"VIRTUAL"
"missing"

"namedList" # the alternative to "list" that preserves
    # the names attribute
```

Objects from the Classes

If a class is not virtual (see section in `Classes_Details`), objects can be created by calls of the form `new(Class, ... )`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.
The class "expression" is slightly odd, in that the ... arguments will not be evaluated; therefore, don't enclose them in a call to quote().

Note that class "list" is a pure vector. Although lists with names go back to the earliest versions of S, they are an extension of the vector concept in that they have an attribute (which can now be a slot) and which is either NULL or a character vector of the same length as the vector. If you want to guarantee that list names are preserved, use class "namedList", rather than "list". Objects from this class must have a names attribute, corresponding to slot "names", of type "character". Internally, R treats names for lists specially, which makes it impractical to have the corresponding slot in class "namedList" be a union of character names and NULL.

Classes and Types

The basic classes include classes for the basic R types. Note that objects of these types will not usually be S4 objects (isS4 will return FALSE), although objects from classes that contain the basic class will be S4 objects, still with the same type. The type as returned by typeof will sometimes differ from the class, either just from a choice of terminology (type "symbol" and class "name", for example) or because there is not a one-to-one correspondence between class and type (most of the classes that inherit from class "language" have type "language", for example).

Extends

The vector classes extend "vector", directly.

Methods

coerce Methods are defined to coerce arbitrary objects to the vector classes, by calling the corresponding basic function, for example, as(x, "numeric") calls as.numeric(x).

---

callGeneric \hspace{1cm} Call the Current Generic Function from a Method

description

A call to callGeneric can only appear inside a method definition. It then results in a call to the current generic function. The value of that call is the value of callGeneric. While it can be called from any method, it is useful and typically used in methods for group generic functions.

Usage

callGeneric(...) 

Arguments

... Optionally, the arguments to the function in its next call. If no arguments are included in the call to callGeneric, the effect is to call the function with the current arguments. See the detailed description for what this really means.
Details

The name and package of the current generic function is stored in the environment of the method definition object. This name is looked up and the corresponding function called.

The statement that passing no arguments to callGeneric causes the generic function to be called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say x, that appears in the original call, there is a corresponding argument in the generated call equivalent to x = x. In effect, this means that the generic function sees the same actual arguments, but arguments are evaluated only once.

Using callGeneric with no arguments is prone to creating infinite recursion, unless one of the arguments in the signature has been modified in the current method so that a different method is selected.

Value

The value returned by the new call.

References

Chambers, John M. (2016) Extending R, Chapman & Hall. (Chapters 9 and 10.)

GroupGenericFunctions for other information about group generic functions; Methods_Details for the general behavior of method dispatch

Examples

```r
## the method for group generic function Ops
## for signature( e1="structure", e2="vector")
function (e1, e2) {
  value <- callGeneric(e1@.Data, e2)
  if (length(value) == length(e1)) {
    e1@.Data <- value
    e1
  } else value
}

## For more examples
## Not run:
showMethods("Ops", includeDefs = TRUE)

## End(Not run)
```
**callNextMethod**

### Description

A call to `callNextMethod` can only appear inside a method definition. It then results in a call to the first inherited method after the current method, with the arguments to the current method passed down to the next method. The value of that method call is the value of `callNextMethod`.

### Usage

```
callNextMethod(...)```

### Arguments

```
...```

Optionally, the arguments to the function in its next call (but note that the dispatch is as in the detailed description below; the arguments have no effect on selecting the next method.)

If no arguments are included in the call to `callNextMethod`, the effect is to call the method with the current arguments. See the detailed description for what this really means.

Calling with no arguments is often the natural way to use `callNextMethod`; see the examples.

### Details

The ‘next’ method (i.e., the first inherited method) is defined to be that method which *would* have been called if the current method did not exist. This is more-or-less literally what happens: The current method (to be precise, the method with signature given by the defined slot of the method from which `callNextMethod` is called) is deleted from a copy of the methods for the current generic, and `selectMethod` is called to find the next method (the result is cached in the method object where the call occurred, so the search typically happens only once per session per combination of argument classes).

The next method is defined from the *signature* of the current method, not from the actual classes of the arguments. In particular, modifying any of the arguments has no effect on the selection. As a result, the selected next method can be called with invalid arguments if the calling function assigns objects of a different class before the `callNextMethod()` call. Be careful of any assignments to such arguments.

It is possible for the selection of the next method to be ambiguous, even though the original set of methods was consistent. See the section “Ambiguous Selection”.

The statement that the method is called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that “missing” is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the next method call equivalent to `x = x`. In effect, this means that the next method sees the same actual arguments, but arguments are evaluated only once.

### Value

The value returned by the selected method.
Ambiguous Selection

There are two fairly common situations in which the choice of a next method is ambiguous, even when the original set of methods uniquely defines all method selection unambiguously. In these situations, callNextMethod() should be replaced, either by a call to a specific function or by recalling the generic with different arguments.

The most likely situation arises with methods for binary operators, typically through one of the group generic functions. See the example for class "rnum" below. Examples of this sort usually require three methods: two for the case that the first or the second argument comes from the class, and a third for the case that both arguments come from the class. If that last method uses callNextMethod, the other two methods are equally valid. The ambiguity is exactly the same that required defining the two-argument method in the first place.

In fact, the two possibilities are equally valid conceptually as well as formally. As in the example below, the logic of the application usually requires selecting a computation explicitly or else calling the generic function with modified arguments to select an appropriate method.

The other likely source of ambiguity arises from a class that inherits directly from more than one other class (a “mixin” in standard terminology). If the generic has methods corresponding to both superclasses, a method for the current class is again needed to resolve ambiguity. Using callNextMethod will again reimpose the ambiguity. Again, some explicit choice has to be made in the calling method instead.

These ambiguities are not the result of bad design, but they do require workarounds. Other ambiguities usually reflect inconsistencies in the tree of inheritances, such as a class appearing in more than one place among the superclasses. Such cases should be rare, but with the independent definition of classes in multiple packages, they can’t be ruled out.

callGeneric to call the generic function with the current dispatch rules (typically for a group generic function); Methods_Details for the general behavior of method dispatch.

Examples

```r
## callNextMethod() used for the Math, Math2 group generic functions
## A class to automatically round numeric results to "d" digits
rnum <- setClass("rnum", slots = c(d = "integer"), contains = "numeric")
## Math functions operate on the rounded numbers, return a plain vector. The next method will always be the default, usually a primitive.
setMethod("Math", "rnum",
  function(x)
    callNextMethod(round(as.numeric(x), x@d)))
setMethod("Math2", "rnum",
  function(x, digits)
    callNextMethod(round(as.numeric(x), x@d), digits))
## Examples of callNextMethod with two arguments in the signature.
## For arithmetic and one rnum with anything, callNextMethod with no arguments
```
## round the full accuracy result, and return as plain vector

```r
setMethod("Arith", c(e1 = "rnum"),
  function(e1, e2)
    as.numeric(round(callNextMethod(), e1@d)))
setMethod("Arith", c(e2 = "rnum"),
  function(e1, e2)
    as.numeric(round(callNextMethod(), e2@d)))
```

## A method for BOTH arguments from "rnum" would be ambiguous
## for callNextMethod(): the two methods above are equally valid.
## The method chooses the smaller number of digits,
## and then calls the generic function, postponing the method selection
## until it's not ambiguous.

```r
setMethod("Arith", c(e1 = "rnum", e2 = "rnum"),
  function(e1, e2) {
    if(e1@d <= e2@d)
      callGeneric(e1, as.numeric(e2))
    else
      callGeneric(as.numeric(e1), e2)
  })
```

## For comparisons, callNextMethod with the rounded arguments

```r
setMethod("Compare", c(e1 = "rnum"),
  function(e1, e2)
    callNextMethod(round(e1, e1@d), round(e2, e1@d)))
setMethod("Compare", c(e2 = "rnum"),
  function(e1, e2)
    callNextMethod(round(e1, e2@d), round(e2, e2@d)))
```

## similarly to the Arith case, the method for two "rnum" objects
## can not unambiguously use callNextMethod(). Instead, we rely on
## The rnum() method inherited from Math2 to return plain vectors.

```r
setMethod("Compare", c(e1 = "rnum", e2 = "rnum"),
  function(e1, e2) {
    d <- min(e1@d, e2@d)
    callGeneric(round(e1, d), round(e2, d))
  })
```

set.seed(867)

```r
x1 <- rnum(10*runif(5), d=1L)
x2 <- rnum(10*runif(5), d=2L)
x1+1
x2*2
x1-x2
```

## Simple examples to illustrate callNextMethod with and without arguments

```r
B0 <- setClass("B0", slots = c(s0 = "numeric"))
```

## and a function to illustrate callNextMethod

```r
f <- function(x, text = "default") {
  str(x) # print a summary
```
paste(text, ":", class(x))
)

setGeneric("f")
setMethod("f", "B0", function(x, text = "B0") {
  cat("B0 method called with s0 =", x@s0, "\n")
callNextMethod()
})

b0 <- B0(s0 = 1)

## call f() with 2 arguments: callNextMethod passes both to the default method
f(b0, "first test")

## call f() with 1 argument: the default "B0" is not passed by callNextMethod
f(b0)

## Now, a class that extends B0, with no methods for f()
B1 <- setClass("B1", slots = c(s1 = "character"), contains = "B0")
b1 <- B1(s0 = 2, s1 = "Testing B1")

## the two cases work as before, by inheriting the "B0" method
f(b1, b1@s1)

f(b1)

B2 <- setClass("B2", contains = "B1")

## And, a method for "B2" that calls with explicit arguments.
## Note that the method selection in callNextMethod
## uses the class of the *argument* to consistently select the "B0" method
setMethod("f", "B2", function(x, text = "B1 method") {
  y <- B1(s0 = -x@s0, s1 = "Modified x")
callNextMethod(y, text)
})

b2 <- B2(s1 = "Testing B2", s0 = 10)

f(b2, b2@s1)

f(b2)

## Be careful: the argument passed must be legal for the method selected
## Although the argument here is numeric, it's still the "B0" method that's called
setMethod("f", "B2", function(x, text = "B1 method") {
  callNextMethod(x@s0, text)
})

## Now the call will cause an error:
tryCatch(f(b2), error = function(e) cat(e$message, "\n"))
canCoerce

Can an Object be Coerced to a Certain S4 Class?

Description

Test if an object can be coerced to a given S4 class. Maybe useful inside if() to ensure that calling as(object, Class) will find a method.

Usage

canCoerce(object, Class)

Arguments

object any R object, typically of a formal S4 class.
Class an S4 class (see isClass).

Value

a scalar logical, TRUE if there is a coerce method (as defined by e.g. setAs) for the signature (from = class(object), to = Class).

See Also

as, setAs, selectMethod, setClass.

Examples

m <- matrix(pi, 2,3)
canCoerce(m, "numeric") # TRUE
canCoerce(m, "array") # TRUE

cbind2

Combine two Objects by Columns or Rows

Description

Combine two matrix-like R objects by columns (cbind2) or rows (rbind2). These are (S4) generic functions with default methods.

Usage

cbind2(x, y, ...)
rbind2(x, y, ...)

Arguments

x  any R object, typically matrix-like.
y  any R object, typically similar to x, or missing completely.
...
optional arguments for methods.

Details

The main use of cbind2 (rbind2) is to be called recursively by cbind() (rbind()) when both of these requirements are met:

- There is at least one argument that is an S4 object, and
- S3 dispatch fails (see the Dispatch section under cbind).

The methods on cbind2 and rbind2 effectively define the type promotion policy when combining a heterogeneous set of arguments. The homogeneous case, where all objects derive from some S4 class, can be handled via S4 dispatch on the ... argument via an externally defined S4 cbind (rbind) generic.

Since (for legacy reasons) S3 dispatch is attempted first, it is generally a good idea to additionally define an S3 method on cbind (rbind) for the S4 class. The S3 method will be invoked when the arguments include objects of the S4 class, along with arguments of classes for which no S3 method exists. Also, in case there is an argument that selects a different S3 method (like the one for data.frame), this S3 method serves to introduce an ambiguity in dispatch that triggers the recursive fallback to cbind2 (rbind2). Otherwise, the other S3 method would be called, which may not be appropriate.

Value

A matrix (or matrix like object) combining the columns (or rows) of x and y. Note that methods must construct colnames and rownames from the corresponding column and row names of x and y (but not from deparsing argument names such as in cbind(..., deparse.level = d) for d \geq 1).

Methods

signature(x = "ANY", y = "ANY") the default method using R's internal code.
signature(x = "ANY", y = "missing") the default method for one argument using R’s internal code.

See Also

cbind, rbind; further, cBind, rBind in the Matrix package.

Examples

cbind2(1:3, 4)
m <- matrix(3:8, 2,3, dimnames=list(c("a","b"), LETTERS[1:3]))
cbind2(1:2, m) # keeps dimnames from m

## rbind() and cbind() now make use of rbind2()/cbind2() methods
setClass("Num", contains="numeric")
setMethod("cbind2", c("Num", "missing"),
  function(x,y,...) \{ cat("Num-miss--meth\n"); as.matrix(x)\})
setMethod("cbind2", c("Num","ANY"), function(x,y,...) \{

classesToAM

Compute an Adjacency Matrix for Superclasses of Class Definitions

Description

Given a vector of class names or a list of class definitions, the function returns an adjacency matrix of the superclasses of these classes; that is, a matrix with class names as the row and column names and with element [i, j] being 1 if the class in column j is a direct superclass of the class in row i, and 0 otherwise.

The matrix has the information implied by the contains slot of the class definitions, but in a form that is often more convenient for further analysis; for example, an adjacency matrix is used in packages and other software to construct graph representations of relationships.

Usage

classesToAM(classes, includeSubclasses = FALSE, abbreviate = 2)
Arguments

- **classes**: Either a character vector of class names or a list, whose elements can be either class names or class definitions. The list is convenient, for example, to include the package slot for the class name. See the examples.

- **includeSubclasses**: A logical flag; if TRUE, then the matrix will include all the known subclasses of the specified classes as well as the superclasses. The argument can also be a logical vector of the same length as classes, to include subclasses for some but not all the classes.

- **abbreviate**: Control of the abbreviation of the row and/or column labels of the matrix returned: values 0, 1, 2, or 3 abbreviate neither, rows, columns or both. The default, 2, is useful for printing the matrix, since class names tend to be more than one character long, making for spread-out printing. Values of 0 or 3 would be appropriate for making a graph (3 avoids the tendency of some graph plotting software to produce labels in minuscule font size).

Details

For each of the classes, the calculation gets all the superclass names from the class definition, and finds the edges in those classes’ definitions; that is, all the superclasses at distance 1. The corresponding elements of the adjacency matrix are set to 1.

The adjacency matrices for the individual class definitions are merged. Note two possible kinds of inconsistency, neither of which should cause problems except possibly with identically named classes from different packages. Edges are computed from each superclass definition, so that information overrides a possible inference from extension elements with distance > 1 (and it should). When matrices from successive classes in the argument are merged, the computations do not currently check for inconsistencies—this is the area where possible multiple classes with the same name could cause confusion. A later revision may include consistency checks.

Value

As described, a matrix with entries 0 or 1, non-zero values indicating that the class corresponding to the column is a direct superclass of the class corresponding to the row. The row and column names are the class names (without package slot).

See Also

- **extends** and **classRepresentation** for the underlying information from the class definition.

Examples

```r
# the super- and subclasses of "standardGeneric"
# and "derivedDefaultMethod"
am <- classesToAM(list(class(show), class(getMethod(show))), TRUE)
am

# Not run:
# the following function depends on the Bioconductor package Rgraphviz
plotInheritance <- function(classes, subclasses = FALSE, ...) {
  if(!require("Rgraphviz", quietly=TRUE))
    stop("Only implemented if Rgraphviz is available")
  mm <- classesToAM(classes, subclasses)
classes <- rownames(mm); rownames(mm) <- colnames(mm)
```
Classes_Details

Description

Class definitions are objects that contain the formal definition of a class of R objects, usually referred to as an S4 class, to distinguish them from the informal S3 classes. This document gives an overview of S4 classes; for details of the class representation objects, see help for the class classRepresentation.

Metadata Information

When a class is defined, an object is stored that contains the information about that class. The object, known as the metadata defining the class, is not stored under the name of the class (to allow programmers to write generating functions of that name), but under a specially constructed name. To examine the class definition, call getClass. The information in the metadata object includes:

Slots: The data contained in an object from an S4 class is defined by the slots in the class definition. Each slot in an object is a component of the object; like components (that is, elements) of a list, these may be extracted and set, using the function slot() or more often the operator "@". However, they differ from list components in important ways. First, slots can only be referred to by name, not by position, and there is no partial matching of names as with list elements.

All the objects from a particular class have the same set of slot names; specifically, the slot names that are contained in the class definition. Each slot in each object always is an object of the class specified for this slot in the definition of the current class. The word "is" corresponds to the R function of the same name (is), meaning that the class of the object in the slot must be the same as the class specified in the definition, or some class that extends the one in the definition (a subclass).

A special slot name, .Data, stands for the ‘data part’ of the object. An object from a class with a data part is defined by specifying that the class contains one of the R object types or one of the special pseudo-classes, matrix or array, usually because the definition of the class, or of one of its superclasses, has included the type or pseudo-class in its contains argument. A second special slot name, .xData, is used to enable inheritance from abnormal types such as "environment" See the section on inheriting from non-S4 classes for details on the representation and for the behavior of S3 methods with objects from these classes.

Some slot names correspond to attributes used in old-style S3 objects and in R objects without an explicit class, for example, the names attribute. If you define a class for which that attribute

```r
graph <- new("graphAM", mm, "directed", ...) plot(graph) cat("Key:\n", paste(abbreviate(classes), " = ", classes, ", ", sep = ""), sep = "", fill = TRUE) invisible(graph) }

## The plot of the class inheritance of the package "graph"
require(graph) plotInheritance(getClasses("package:graph"))

## End(Not run)
```
will be set, such as a subclass of named vectors, you should include "names" as a slot. See the definition of class "namedList" for an example. Using the names() assignment to set such names will generate a warning if there is no names slot and an error if the object in question is not a vector type. A slot called "names" can be used anywhere, but only if it is assigned as a slot, not via the default names() assignment.

**Superclasses:** The definition of a class includes the *superclasses* — the classes that this class extends. A class Fancy, say, extends a class Simple if an object from the Fancy class has all the capabilities of the Simple class (and probably some more as well). In particular, and very usefully, any method defined to work for a Simple object can be applied to a Fancy object as well.

This relationship is expressed equivalently by saying that Simple is a superclass of Fancy, or that Fancy is a subclass of Simple.

The direct superclasses of a class are those superclasses explicitly defined. Direct superclasses can be defined in three ways. Most commonly, the superclasses are listed in the contains= argument in the call to setClass that creates the subclass. In this case the subclass will contain all the slots of the superclass, and the relation between the class is called **simple**, as it in fact is. Superclasses can also be defined explicitly by a call to setIs; in this case, the relation requires methods to be specified to go from subclass to superclass. Thirdly, a class union is a superclass of all the members of the union. In this case too the relation is simple, but notice that the relation is defined when the superclass is created, not when the subclass is created as with the contains= mechanism.

The definition of a superclass will also potentially contain its own direct superclasses. These are considered (and shown) as superclasses at distance 2 from the original class; their direct superclasses are at distance 3, and so on. All these are legitimate superclasses for purposes such as method selection.

When superclasses are defined by including the names of superclasses in the contains= argument to setClass, an object from the class will have all the slots defined for its own class and all the slots defined for all its superclasses as well.

The information about the relation between a class and a particular superclass is encoded as an object of class SClassExtension. A list of such objects for the superclasses (and sometimes for the subclasses) is included in the metadata object defining the class. If you need to compute with these objects (for example, to compare the distances), call the function extends with argument fullInfo=TRUE.

**Prototype:** The objects from a class created by a call to new are defined by the prototype object for the class and by additional arguments in the call to new, which are passed to a method for that class for the function initialize.

Each class representation object contains a prototype object for the class (although for a virtual class the prototype may be NULL). The prototype object must have values for all the slots of the class. By default, these are the prototypes of the corresponding slot classes. However, the definition of the class can specify any valid object for any of the slots.

**Basic classes**

There are a number of 'basic' classes, corresponding to the ordinary kinds of data occurring in R. For example, "numeric" is a class corresponding to numeric vectors. The other vector basic classes are "logical", "integer", "complex", "character", "raw", "list" and "expression". The prototypes for the vector classes are vectors of length 0 of the corresponding type. Notice that basic classes are unusual in that the prototype object is from the class itself.

In addition to the vector classes there are also basic classes corresponding to objects in the language, such as "function" and "call". These classes are subclasses of the virtual class "language". Finally, there are object types and corresponding basic classes for "abnormal" objects, such as
"environment" and "externalptr". These objects do not follow the functional behavior of the language; in particular, they are not copied and so cannot have attributes or slots defined locally.

All these classes can be used as slots or as superclasses for any other class definitions, although they do not themselves come with an explicit class. For the abnormal object types, a special mechanism is used to enable inheritance as described below.

Inheriting from non-S4 Classes

A class definition can extend classes other than regular S4 classes, usually by specifying them in the contains= argument to setClass. Three groups of such classes behave distinctly:

1. S3 classes, which must have been registered by a previous call to setOldClass (you can check that this has been done by calling getClass, which should return a class that extends oldClass);
2. One of the R object types, typically a vector type, which then defines the type of the S4 objects, but also a type such as environment that can not be used directly as a type for an S4 object. See below.
3. One of the pseudo-classes matrix and array, implying objects with arbitrary vector types plus the dim and dimnames attributes.

This section describes the approach to combining S4 computations with older S3 computations by using such classes as superclasses. The design goal is to allow the S4 class to inherit S3 methods and default computations in as consistent a form as possible.

As part of a general effort to make the S4 and S3 code in R more consistent, when objects from an S4 class are used as the first argument to a non-default S3 method, either for an S3 generic function (one that calls UseMethod) or for one of the primitive functions that dispatches S3 methods, an effort is made to provide a valid object for that method. In particular, if the S4 class extends an S3 class or matrix or array, and there is an S3 method matching one of these classes, the S4 object will be coerced to a valid S3 object, to the extent that is possible given that there is no formal definition of an S3 class.

For example, suppose "myFrame" is an S4 class that includes the S3 class "data.frame" in the contains= argument to setClass. If an object from this S4 class is passed to a function, say as.matrix, that has an S3 method for "data.frame", the internal code for UseMethod will convert the object to a data frame; in particular, to an S3 object whose class attribute will be the vector corresponding to the S3 class (possibly containing multiple class names). Similarly for an S4 object inheriting from "matrix" or "array", the S4 object will be converted to a valid S3 matrix or array.

Note that the conversion is not applied when an S4 object is passed to the default S3 method. Some S3 generics attempt to deal with general objects, including S4 objects. Also, no transformation is applied to S4 objects that do not correspond to a selected S3 method; in particular, to objects from a class that does not contain either an S3 class or one of the basic types. See asS4 for the transformation details.

In addition to explicit S3 generic functions, S3 methods are defined for a variety of operators and functions implemented as primitives. These methods are dispatched by some internal C code that operates partly through the same code as real S3 generic functions and partly via special considerations (for example, both arguments to a binary operator are examined when looking for methods). The same mechanism for adapting S4 objects to S3 methods has been applied to these computations as well, with a few exceptions such as generating an error if an S4 object that does not extend an appropriate S3 class or type is passed to a binary operator.

The remainder of this section discusses the mechanisms for inheriting from basic object types. See matrix or array for inhering from the matrix and array pseudo-classes, or from time-series. For the corresponding details for inheritance from S3 classes, see setOldClass.
An object from a class that directly and simply contains one of the basic object types in R, has implicitly a corresponding .Data slot of that type, allowing computations to extract or replace the data part while leaving other slots unchanged. If the type is one that can accept attributes and is duplicated normally, the inheritance also determines the type of the object; if the class definition has a .Data slot corresponding to a normal type, the class of the slot determines the type of the object (that is, the value of typeof(x)). For such classes, .Data is a pseudo-slot; that is, extracting or setting it modifies the non-slot data in the object. The functions getDataPart and setDataPart are a cleaner, but essentially equivalent way to deal with the data part.

Extending a basic type this way allows objects to use old-style code for the corresponding type as well as S4 methods. Any basic type can be used for .Data, but a few types are treated differently because they do not behave like ordinary objects; for example, "NULL", environments, and external pointers. Classes extend these types by having a slot, .xData, itself inherited from an internally defined S4 class. This slot actually contains an object of the inherited type, to protect computations from the reference semantics of the type. Coercing to the nonstandard object type then requires an actual computation, rather than the "simple" inclusion for other types and classes. The intent is that programmers will not need to take account of the mechanism, but one implication is that you should not explicitly use the type of an S4 object to detect inheritance from an arbitrary object type. Use is and similar functions instead.

### className

| className | Class names including the corresponding package |

#### Description

The function `className()` generates a valid references to a class, including the name of the package containing the class definition. The object returned, from class "className", is the unambiguous way to refer to a class, for example when calling `setMethod`, just in case multiple definitions of the class exist.

Function "multipleClasses" returns information about multiple definitions of classes with the same name from different packages.

#### Usage

```r
className(class, package)
multipleClasses(details = FALSE)
```
Arguments

class, package  The character string name of a class and, optionally, of the package to which it
belongs. If argument package is missing and the class argument has a package
slot, that is used (in particular, passing in an object from class "className"
returns itself in this case, but changes the package slot if the second argument is
supplied).

If there is no package argument or slot, a definition for the class must exist and
will be used to define the package. If there are multiple definitions, one will be
chosen and a warning printed giving the other possibilities.

details  If FALSE, the default, multipleClasses() returns a character vector of those
classes currently known with multiple definitions.

If TRUE, a named list of those class definitions is returned. Each element of
the list is itself a list of the corresponding class definitions, with the package
names as the names of the list. Note that identical class definitions will not be
considered “multiple” definitions (see the discussion of the details below).

Details

The table of class definitions used internally can maintain multiple definitions for classes with the
same name but coming from different packages. If identical class definitions are encountered, only
one class definition is kept; this occurs most often with S3 classes that have been specified in calls to
setOldClass. For true classes, multiple class definitions are unavoidable in general if two packages
happen to have used the same name, independently.

Overriding a class definition in another package with the same name deliberately is usually a bad
idea. Although R attempts to keep and use the two definitions (as of version 2.14.0), ambiguities
are always possible. It is more sensible to define a new class that extends an existing class but has
a different name.

Value

A call to className() returns an object from class "className".

A call to multipleClasses() returns either a character vector or a named list of class definitions.
In either case, testing the length of the returned value for being greater than 0 is a check for the
existence of multiply defined classes.

Objects from the Class

The class "className" extends "character" and has a slot "package", also of class
"character".

Examples

## Not run:
className("vector") # will be found, from package "methods"
className("vector", "magic") # OK, even though the class doesn't exist

className("An unknown class") # Will cause an error

## End(Not run)
classRepresentation-class

Class Objects

Description
These are the objects that hold the definition of classes of objects. They are constructed and stored as meta-data by calls to the function setClass. Don’t manipulate them directly, except perhaps to look at individual slots.

Details
Class definitions are stored as metadata in various packages. Additional metadata supplies information on inheritance (the result of calls to setIs). Inheritance information implied by the class definition itself (because the class contains one or more other classes) is also constructed automatically.

When a class is to be used in an R session, this information is assembled to complete the class definition. The completion is a second object of class “classRepresentation”, cached for the session or until something happens to change the information. A call to getClass returns the completed definition of a class; a call to getClassDef returns the stored definition (uncompleted).

In particular, completion fills in the upward- and downward-pointing inheritance information for the class, in slots contains and subclasses respectively. It’s in principle important to note that this information can depend on which packages are installed, since these may define additional subclasses or superclasses.

Slots

- slots: A named list of the slots in this class; the elements of the list are the classes to which the slots must belong (or extend), and the names of the list gives the corresponding slot names.
- contains: A named list of the classes this class ‘contains’; the elements of the list are objects of SClassExtension. The list may be only the direct extensions or all the currently known extensions (see the details).
- virtual: Logical flag, set to TRUE if this is a virtual class.
- prototype: The object that represents the standard prototype for this class; i.e., the data and slots returned by a call to new for this class with no special arguments. Don’t mess with the prototype object directly.
- validity: Optionally, a function to be used to test the validity of objects from this class. See validObject.
- access: Access control information. Not currently used.
- className: The character string name of the class.
- package: The character string name of the package to which the class belongs. Nearly always the package on which the metadata for the class is stored, but in operations such as constructing inheritance information, the internal package name rules.
- subclasses: A named list of the classes known to extend this class'; the elements of the list are objects of class SClassExtension. The list is currently only filled in when completing the class definition (see the details).
- versionKey: Object of class “externalptr”; eventually will perhaps hold some versioning information, but not currently used.
- sealed: Object of class “logical”; is this class sealed? If so, no modifications are allowed.

Documentation

Using and Creating On-line Documentation for Classes and Methods

Description

Special documentation can be supplied to describe the classes and methods that are created by the software in the methods package. Techniques to access this documentation and to create it in R help files are described here.

Getting documentation on classes and methods

You can ask for on-line help for class definitions, for specific methods for a generic function, and for general discussion of methods for a generic function. These requests use the `?` operator (see `help` for a general description of the operator). Of course, you are at the mercy of the implementer as to whether there is any documentation on the corresponding topics.

Documentation on a class uses the argument `class` on the left of the `?`, and the name of the class on the right; for example,

```
class ? genericFunction
```

to ask for documentation on the class "genericFunction".

When you want documentation for the methods defined for a particular function, you can ask either for a general discussion of the methods or for documentation of a particular method (that is, the method that would be selected for a particular set of actual arguments).

Overall methods documentation is requested by calling the `?` operator with `methods` as the left-side argument and the name of the function as the right-side argument. For example,

```
methods ? initialize
```

Asking for documentation on a particular method is done by giving a function call expression as the right-hand argument to the "?" operator. There are two forms, depending on whether you prefer to give the class names for the arguments or expressions that you intend to use in the actual call.

If you planned to evaluate a function call, say `myFun(x, sqrt(wt))` and wanted to find out something about the method that would be used for this call, put the call on the right of the "?" operator:

```
?myFun(x, sqrt(wt))
```

A method will be selected, as it would be for the call itself, and documentation for that method will be requested. If `myFun` is not a generic function, ordinary documentation for the function will be requested.

If you know the actual classes for which you would like method documentation, you can supply these explicitly in place of the argument expressions. In the example above, if you want method documentation for the first argument having class "maybeNumber" and the second "logical", call the "?" operator, this time with a left-side argument `method`, and with a function call on the right using the class names as arguments:

```
method ? myFun("maybeNumber", "logical")
```
Once again, a method will be selected, this time corresponding to the specified classes, and method documentation will be requested. This version only works with generic functions.

The two forms each have advantages. The version with actual arguments doesn't require you to figure out (or guess at) the classes of the arguments. On the other hand, evaluating the arguments may take some time, depending on the example. The version with class names does require you to pick classes, but it’s otherwise unambiguous. It has a subtler advantage, in that the classes supplied may be virtual classes, in which case no actual argument will have specifically this class. The class "maybeNumber", for example, might be a class union (see the example for setClassUnion).

In either form, methods will be selected as they would be in actual computation, including use of inheritance and group generic functions. See selectMethod for the details, since it is the function used to find the appropriate method.

Writing Documentation for Methods

The on-line documentation for methods and classes uses some extensions to the R documentation format to implement the requests for class and method documentation described above. See the document Writing R Extensions for the available markup commands (you should have consulted this document already if you are at the stage of documenting your software).

In addition to the specific markup commands to be described, you can create an initial, overall file with a skeleton of documentation for the methods defined for a particular generic function:

```r
promptMethods("myFun")
```

will create a file, ‘myFun-methods.Rd’ with a skeleton of documentation for the methods defined for function myFun. The output from promptMethods is suitable if you want to describe all or most of the methods for the function in one file, separate from the documentation of the generic function itself. Once the file has been filled in and moved to the ‘man’ subdirectory of your source package, requests for methods documentation will use that file, both for specific methods documentation as described above, and for overall documentation requested by

```r
methods ? myFun
```

You are not required to use promptMethods, and if you do, you may not want to use the entire file created:

- If you want to document the methods in the file containing the documentation for the generic function itself, you can cut-and-paste to move the \alias lines and the Methods section from the file created by promptMethods to the existing file.

- On the other hand, if these are auxiliary methods, and you only want to document the added or modified software, you should strip out all but the relevant \alias lines for the methods of interest, and remove all but the corresponding \item entries in the Methods section. Note that in this case you will usually remove the first \alias line as well, since that is the marker for general methods documentation on this function (in the example, \alias{myfun-methods}).

If you simply want to direct documentation for one or more methods to a particular R documentation file, insert the appropriate alias.
Description

The “...” argument in R functions is treated specially, in that it matches zero, one or more actual arguments (and so, objects). A mechanism has been added to R to allow “...” as the signature of a generic function. Methods defined for such functions will be selected and called when all the arguments matching “...” are from the specified class or from some subclass of that class.

Using "..." in a Signature

Beginning with version 2.8.0 of R, S4 methods can be dispatched (selected and called) corresponding to the special argument “...”. Currently, “...” cannot be mixed with other formal arguments: either the signature of the generic function is “...” only, or it does not contain “...”. (This restriction may be lifted in a future version.)

Given a suitable generic function, methods are specified in the usual way by a call to `setMethod`. The method definition must be written expecting all the arguments corresponding to “...” to be from the class specified in the method’s signature, or from a class that extends that class (i.e., a subclass of that class).

Typically the methods will pass “...” down to another function or will create a list of the arguments and iterate over that. See the examples below.

When you have a computation that is suitable for more than one existing class, a convenient approach may be to define a union of these classes by a call to `setClassUnion`. See the example below.

Method Selection and Dispatch for "..."

See Methods_Details for a general discussion. The following assumes you have read the “Method Selection and Dispatch” section of that documentation.

A method selecting on “...” is specified by a single class in the call to `setMethod`. If all the actual arguments corresponding to “...” have this class, the corresponding method is selected directly.

Otherwise, the class of each argument and that class’ superclasses are computed, beginning with the first “...” argument. For the first argument, eligible methods are those for any of the classes. For each succeeding argument that introduces a class not considered previously, the eligible methods are further restricted to those matching the argument’s class or superclasses. If no further eligible classes exist, the iteration breaks out and the default method, if any, is selected.

At the end of the iteration, one or more methods may be eligible. If more than one, the selection looks for the method with the least distance to the actual arguments. For each argument, any inherited method corresponds to a distance, available from the `contains` slot of the class definition. Since the same class can arise for more than one argument, there may be several distances associated with it. Combining them is inevitably arbitrary: the current computation uses the minimum distance. Thus, for example, if a method matched one argument directly, one as first generation superclass and another as a second generation superclass, the distances are 0, 1 and 2. The current selection computation would use distance 0 for this method. In particular, this selection criterion tends to use a method that matches exactly one or more of the arguments’ class.

As with ordinary method selection, there may be multiple methods with the same distance. A warning message is issued and one of the methods is chosen (the first encountered, which in this case is rather arbitrary).

Notice that, while the computation examines all arguments, the essential cost of dispatch goes up with the number of distinct classes among the arguments, likely to be much smaller than the number of arguments when the latter is large.
Implementation Details

Methods dispatching on “…” were introduced in version 2.8.0 of R. The initial implementation of the corresponding selection and dispatch is in an R function, for flexibility while the new mechanism is being studied. In this implementation, a local version of standardGeneric is inserted in the generic function’s environment. The local version selects a method according to the criteria above and calls that method, from the environment of the generic function. This is slightly different from the action taken by the C implementation when “…” is not involved. Aside from the extra computing time required, the method is evaluated in a true function call, as opposed to the special context constructed by the C version (which cannot be exactly replicated in R code.) However, situations in which different computational results would be obtained have not been encountered so far, and seem very unlikely.

Methods dispatching on arguments other than “…” are cached by storing the inherited method in the table of all methods, where it will be found on the next selection with the same combination of classes in the actual arguments (but not used for inheritance searches). Methods based on “…” are also cached, but not found quite as immediately. As noted, the selected method depends only on the set of classes that occur in the “…” arguments. Each of these classes can appear one or more times, so many combinations of actual argument classes will give rise to the same effective signature. The selection computation first computes and sorts the distinct classes encountered. This gives a label that will be cached in the table of all methods, avoiding any further search for inherited classes after the first occurrence. A call to `showMethods` will expose such inherited methods.

The intention is that the “…” features will be added to the standard C code when enough experience with them has been obtained. It is possible that at the same time, combinations of “…” with other arguments in signatures may be supported.

Examples

```r
cc <- function(...)c(...)
setGeneric("cc")
setMethod("cc", "character", function(...)paste(...))
setClassUnion("Number", c("numeric", "complex"))
setMethod("cc", "Number", function(...) sum(...))
setClass("cdate", contains = "character", slots = c(date = "Date"))
setClass("vdate", contains = "vector", slots = c(date = "Date"))

cd1 <- new("cdate", "abcdef", date = Sys.Date())
cd2 <- new("vdate", "abcdef", date = Sys.Date())
```
environment-class

Class "environment"

Description

A formal class for R environments.

Objects from the Class

Objects can be created by calls of the form `new("environment", ...)`. The arguments in `...`, if any, should be named and will be assigned to the newly created environment.

Methods

- **coerce** signature(from = "ANY", to = "environment"): calls `as.environment`.
- **initialize** signature(object = "environment"): Implements the assignments in the new environment. Note that the object argument is ignored; a new environment is always created, since environments are not protected by copying.

envRefClass-class

Class "envRefClass"

Description

Support Class to Implement R Objects using Reference Semantics

NOTE:

The software described here is an initial version. The eventual goal is to support reference-style classes with software in R itself or using inter-system interfaces. The current implementation (R version 2.12.0) is preliminary and subject to change, and currently includes only the R-only implementation. Developers are encouraged to experiment with the software, but the description here is more than usually subject to change.

Purpose of the Class

This class implements basic reference-style semantics for R objects. Objects normally do not come directly from this class, but from subclasses defined by a call to setRefClass. The documentation below is technical background describing the implementation, but applications should use the interface documented under setRefClass, in particular the $ operator and field accessor functions as described there.

A Basic Reference Class

The design of reference classes for R divides those classes up according to the mechanism used for implementing references, fields, and class methods. Each version of this mechanism is defined by a basic reference class, which must implement a set of methods and provide some further information used by setRefClass.

The required methods are for operators $ and $<- to get and set a field in an object, and for initialize to initialize objects.

To support these methods, the basic reference class needs to have some implementation mechanism to store and retrieve data from fields in the object. The mechanism needs to be consistent with reference semantics; that is, changes made to the contents of an object are global, seen by any code accessing that object, rather than only local to the function call where the change takes place. As described below, class envRefClass implements reference semantics through specialized use of environment objects. Other basic reference classes may use an interface to a language such as Java or C++ using reference semantics for classes.

Usually, the R user will be able to invoke class methods on the class, using the $ operator. The basic reference class method for $ needs to make this possible. Essentially, the operator must return an R function corresponding to the object and the class method name.

Class methods may include an implementation of data abstraction, in the sense that fields are accessed by “get” and “set” methods. The basic reference class provides this facility by setting the "fieldAccessorGenerator" slot in its definition to a function of one variable. This function will be called by setRefClass with the vector of field names as arguments. The generator function must return a list of defined accessor functions. An element corresponding to a get operation is invoked with no arguments and should extract the corresponding field; an element for a set operation will
evalSource

1071

be invoked with a single argument, the value to be assigned to the field. The implementation needs
to supply the object, since that is not an argument in the method invocation. The mechanism used
currently by envRefClass is described below.
Support Classes
Two virtual classes are supplied to test for reference objects: is(x, "refClass") tests
whether x comes from a class defined using the reference class mechanism described here;
is(x, "refObject") tests whether the object has reference semantics generally, including the
previous classes and also classes inheriting from the R types with reference semantics, such as
"environment".
Installed class methods are "classMethodDefinition" objects, with slots that identify the name
of the function as a class method and the other class methods called from this method. The latter
information is determined heuristically when the class is defined by using the codetools recommended package. This package must be installed when reference classes are defined, but is not
needed in order to use existing reference classes.

evalSource

Use Function Definitions from a Source File without Reinstalling a
Package

Description
Definitions of functions and/or methods from a source file are inserted into a package, using the
trace mechanism. Typically, this allows testing or debugging modified versions of a few functions
without reinstalling a large package.
Usage
evalSource(source, package = "", lock = TRUE, cache = FALSE)
insertSource(source, package = "", functions = , methods = ,
force = )

Arguments
source

A file to be parsed and evaluated by evalSource to find the new function and
method definitions.
The argument to insertSource can be an object of class
"sourceEnvironment" returned from a previous call to evalSource If a
file name is passed to insertSource it calls evalSource to obtain the
corresponding object. See the section on the class for details.

package

Optionally, the name of the package to which the new code corresponds and into
which it will be inserted. Although the computations will attempt to infer the
package if it is omitted, the safe approach is to supply it. In the case of a package
that is not attached to the search list, the package name must be supplied.


functions, methods

Optionally, the character-string names of the functions to be used in the insertion. Names supplied in the functions argument are expected to be defined as functions in the source. For names supplied in the methods argument, a table of methods is expected (as generated by calls to `setMethod`, see the details section); methods from this table will be inserted by `insertSource`. In both cases, the revised function or method is inserted only if it differs from the version in the corresponding package as loaded.

If what is omitted, the results of evaluating the source file will be compared to the contents of the package (see the details section).

lock, cache

Optional arguments to control the actions taken by `evalSource`. If `lock` is `TRUE`, the environment in the object returned will be locked, and so will all its bindings. If cache is `FALSE`, the normal caching of method and class definitions will be suppressed during evaluation of the source file.

The default settings are generally recommended, the lock to support the credibility of the object returned as a snapshot of the source file, and the second so that method definitions can be inserted later by `insertSource` using the trace mechanism.

force

If `FALSE`, only functions currently in the environment will be redefined, using `trace`. If `TRUE`, other objects/functions will be simply assigned. By default, `TRUE` if neither the functions nor the methods argument is supplied.

Details

The source file is parsed and evaluated, suppressing by default the actual caching of method and class definitions contained in it, so that functions and methods can be tested out in a reversible way. The result, if all goes well, is an environment containing the assigned objects and metadata corresponding to method and class definitions in the source file.

From this environment, the objects are inserted into the package, into its namespace if it has one, for use during the current session or until reverting to the original version by a call to `untrace`. The insertion is done by calls to the internal version of `trace`, to make reversion possible.

Because the trace mechanism is used, only function-type objects will be inserted, functions themselves or S4 methods.

When the functions and methods arguments are both omitted, `insertSource` selects all suitable objects from the result of evaluating the source file.

In all cases, only objects in the source file that differ from the corresponding objects in the package are inserted. The definition of “differ” is that either the argument list (including default expressions) or the body of the function is not identical. Note that in the case of a method, there need be no specific method for the corresponding signature in the package: the comparison is made to the method that would be selected for that signature.

Nothing in the computation requires that the source file supplied be the same file as in the original package source, although that case is both likely and sensible if one is revising the package.

Nothing in the computations compares source files: the objects generated by evaluating source are compared as objects to the content of the package.

Value

An object from class "sourceEnvironment", a subclass of "environment" (see the section on the class) The environment contains the versions of all object resulting from evaluation of the source file. The class also has slots for the time of creation, the source file and the package name. Future extensions may use these objects for versioning or other code tools.
The object returned can be used in debugging (see the section on that topic) or as the source argument in a future call to `insertSource`. If only some of the revised functions were inserted in the first call, others can be inserted in a later call without re-evaluating the source file, by supplying the environment and optionally suitable functions and/or methods argument.

**Debugging**

Once a function or method has been inserted into a package by `insertSource`, it can be studied by the standard debugging tools; for example, `debug` or the various versions of `trace`. Calls to `trace` should take the extra argument `edit = env`, where `env` is the value returned by the call to `evalSource`. The trace mechanism has been used to install the revised version from the source file, and supplying the argument ensures that it is this version, not the original, that will be traced. See the example below.

To turn tracing off, but retain the source version, use `trace(x, edit = env)` as in the example. To return to the original version from the package, use `untrace(x)`.

**Class "sourceEnvironment"**

Objects from this class can be treated as environments, to extract the version of functions and methods generated by `evalSource`. The objects also have the following slots:

- `packageName`: The character-string name of the package to which the source code corresponds.
- `dateCreated`: The date and time that the source file was evaluated (usually from a call to `Sys.time`).
- `sourceFile`: The character-string name of the source file used.

Note that using the environment does not change the `dateCreated`.

**See Also**

`trace` for the underlying mechanism, and also for the `edit=` argument that can be used for somewhat similar purposes; that function and also `debug` and `setBreakpoint`, for techniques more oriented to traditional debugging styles. The present function is directly intended for the case that one is modifying some of the source for an existing package, although it can be used as well by inserting debugging code in the source (more useful if the debugging involved is non-trivial). As noted in the details section, the source file need not be the same one in the original package source.

**Examples**

```r
## Not run:
## Suppose package P0 has a source file "all.R"
## First, evaluate the source, and from it
## insert the revised version of methods for summary()
env <- insertSource("./P0/R/all.R", package = "P0",
                   methods = "summary")
## now test one of the methods, tracing the version from the source
trace("summary", signature = "myMat", browser, edit = env)
## After testing, remove the browser() call but keep the source
trace("summary", signature = "myMat", edit = env)
## Now insert all the (other) revised functions and methods
## without re-evaluating the source file.
## The package name is included in the object env.
insertSource(env)
## End(Not run)
```
findClass  

Find Class Definitions

Description

Functions to find classes: isClass tests for a class; findClass returns the name(s) of packages containing the class; getClasses returns the names of all the classes in an environment, typically a namespace. To examine the definition of a class, use getClass.

Usage

isClass(Class, formal=TRUE, where)

getClasses(where, inherits = missing(where))

findClass(Class, where, unique = "")

## The remaining functions are retained for compatibility
## but not generally recommended

removeClass(Class, where)

resetClass(Class, classDef, where)

sealClass(Class, where)

Arguments

Class  character string name for the class. The functions will usually take a class definition instead of the string. To restrict the class to those defined in a particular package, set the packageSlot of the character string.

where  the environment in which to search for the class definition. Defaults to the top-level environment of the calling function. When called from the command line, this has the effect of using all the package environments in the search list.

To restrict the search to classes in a particular package, use where = asNamespace(pkg) with pkg the package name; to restrict it to the exported classes, use where = "package:pkg" after the package is attached to the search list.

formal  logical is a formal definition required? For S compatibility, and always treated as TRUE.

unique  if findClass expects a unique location for the class, unique is a character string explaining the purpose of the search (and is used in warning and error messages). By default, multiple locations are possible and the function always returns a list.

inherits  in a call to getClasses, should the value returned include all parent environments of where, or that environment only? Defaults to TRUE if where is omitted, and to FALSE otherwise.

classDef  For resetClass, the optional class definition.
Functions

isClass: Is this the name of a formally defined class?

getClasses: The names of all the classes formally defined on where. If called with no argument, all the classes visible from the calling function (if called from the top-level, all the classes in any of the environments on the search list). The where argument is used to search only in a particular package.

findClass: The list of environments in which a class definition of Class is found. If where is supplied, a list is still returned, either empty or containing the environment corresponding to where. By default when called from the \texttt{R} session, the global environment and all the currently attached packages are searched.

If unique is supplied as a character string, findClass will warn if there is more than one definition visible (using the string to identify the purpose of the call), and will generate an error if no definition can be found.

The remaining functions are retained for back-compatibility and internal use, but not generally recommended.

removeClass: Remove the definition of this class. This can’t be used if the class is in another package, and would rarely be needed in source code defining classes in a package.

resetClass: Reset the internal definition of a class. Not legitimate for a class definition not in this package and rarely needed otherwise.

sealClass: Seal the current definition of the specified class, to prevent further changes, by setting the corresponding slot in the class definition. This is rarely used, since classes in loaded packages are sealed by locking their namespace.

\textbf{findMethods}

\textit{Description of the Methods Defined for a Generic Function}

Description

The function \texttt{findMethods} converts the methods defined in a table for a generic function (as used for selection of methods) into a list, for study or display. The list is actually from the class \texttt{listOfMethods} (see the section describing the class, below).

The list will be limited to the methods defined in environment where if that argument is supplied and limited to those including one or more of the specified \texttt{classes} in the method signature if that argument is supplied.

To see the actual table (an environment) used for methods dispatch, call \texttt{getMethodsForDispatch}. The names of the list returned by \texttt{findMethods} are the names of the objects in the table.
1076

findMethods

The function findMethodSignatures returns a character matrix whose rows are the class names
from the signature of the corresponding methods; it operates either from a list returned by
findMethods, or by computing such a list itself, given the same arguments as findMethods .
The function hasMethods returns TRUE or FALSE according to whether there is a non-empty table
of methods for function f in the environment or search position where (or for the generic function
generally if where is missing).
The defunct function getMethods is an older alternative to findMethods , returning information
in the form of an object of class MethodsList, previously used for method dispatch. It is not
recommended, since this class of objects is deprecated generally and will disappear in a future
version of R.
Usage
findMethods(f, where, classes = character(), inherited = FALSE,
package = "")
findMethodSignatures(..., target = TRUE, methods = )
hasMethods(f, where, package)
## Deprecated in 2010 and defunct in 2015 for \code{table = FALSE}:
getMethods(f, where, table = FALSE)
Arguments
f

A generic function or the character-string name of one.

where

Optionally, an environment or position on the search list to look for methods
metadata.
If where is missing, findMethods uses the current table of methods in the
generic function itself, and hasMethods looks for metadata anywhere in the
search list.

table

If TRUE in a call to getMethods the returned value is the table used for dispatch,
including inherited methods discovered to date. Used internally, but since the
default result is the now unused mlist object, the default will likely be changed
at some point.

classes

If supplied, only methods whose signatures contain at least one of the supplied
classes will be included in the value returned.

inherited

Logical flag; if TRUE, the table of all methods, inherited or defined directly,
will be used; otherwise, only the methods explicitly defined. Option TRUE is
meaningful only if where is missing.

...

In the call to findMethodSignatures, any arguments that might be given to
findMethods.

target

Optional flag to findMethodSignatures; if TRUE, the signatures used are the
target signatures (the classes for which the method will be selected); if FALSE,
they will be the signatures are defined. The difference is only meaningful if
inherited is TRUE.

methods

In the call to findMethodSignatures, an optional list of methods, presumably
returned by a previous call to findMethods. If missing, that function will be
call with the . . . arguments.


In a call to `hasMethods`, the package name for the generic function (e.g., "base" for primitives). If missing this will be inferred either from the "package" attribute of the function name, if any, or from the package slot of the generic function. See 'Details'.

**Details**

The functions obtain a table of the defined methods, either from the generic function or from the stored metadata object in the environment specified by `where`. In a call to `getMethods`, the information in the table is converted as described above to produce the returned value, except with the table argument.

Note that `hasMethods`, but not the other functions, can be used even if no generic function of this name is currently found. In this case `package` must either be supplied as an argument or included as an attribute of `f`, since the package name is part of the identification of the methods tables.

### The Class for lists of methods

The class "listOfMethods" returns the methods as a named list of method definitions (or a primitive function, see the slot documentation below). The names are the strings used to store the corresponding objects in the environment from which method dispatch is computed. The current implementation uses the names of the corresponding classes in the method signature, separated by "#" if more than one argument is involved in the signature.

**Slots**

- `.Data`: Object of class "list". The method definitions.
  
  Note that these may include the primitive function itself as default method, when the generic corresponds to a primitive. (Basically, because primitive functions are abnormal R objects, which cannot currently be extended as method definitions.) Computations that use the returned list to derive other information need to take account of this possibility. See the implementation of `findMethodSignatures` for an example.

- `arguments`: Object of class "character". The names of the formal arguments in the signature of the generic function.

- `signatures`: Object of class "list". A list of the signatures of the individual methods. This is currently the result of splitting the names according to the "#" separator.
  
  If the object has been constructed from a table, as when returned by `findMethods`, the signatures will all have the same length. However, a list rather than a character matrix is used for generality. Calling `findMethodSignatures` as in the example below will always convert to the matrix form.

- `generic`: Object of class "genericFunction". The generic function corresponding to these methods. There are plans to generalize this slot to allow reference to the function.

- `names`: Object of class "character". The names as noted are the class names separated by "#".

**Extends**

- Class "namedList", directly.
- Class "list", by class "namedList", distance 2.
- Class "vector", by class "namedList", distance 3.

**See Also**

`showMethods`, `selectMethod`, `Methods_Details`
Examples

```r
mm <- findMethods("Ops")
findMethodSignatures(methods = mm)
```

Description

Beginning with R version 1.8.0, the class of an object contains the identification of the package in which the class is defined. The function `fixPre1.8` fixes and re-assigns objects missing that information (typically because they were loaded from a file saved with a previous version of R.)

Usage

`fixPre1.8(names, where)`

Arguments

- `names`: Character vector of the names of all the objects to be fixed and re-assigned.
- `where`: The environment from which to look for the objects, and for class definitions. Defaults to the top environment of the call to `fixPre1.8`, the global environment if the function is used interactively.

Details

The named object will be saved where it was found. Its class attribute will be changed to the full form required by R 1.8; otherwise, the contents of the object should be unchanged.

Objects will be fixed and re-assigned only if all the following conditions hold:

1. The named object exists.
2. It is from a defined class (not a basic datatype which has no actual class attribute).
3. The object appears to be from an earlier version of R.
4. The class is currently defined.
5. The object is consistent with the current class definition.

If any condition except the second fails, a warning message is generated.

Note that `fixPre1.8` currently fixes only the change in class attributes. In particular, it will not fix binary versions of packages installed with earlier versions of R if these use incompatible features. Such packages must be re-installed from source, which is the wise approach always when major version changes occur in R.

Value

The names of all the objects that were in fact re-assigned.
**genericFunction-class**  
*Generic Function Objects*

**Description**

Generic functions (objects from or extending class `genericFunction`) are extended function objects, containing information used in creating and dispatching methods for this function. They also identify the package associated with the function and its methods.

**Objects from the Class**

Generic functions are created and assigned by `setGeneric` or `setGroupGeneric` and, indirectly, by `setMethod`.

As you might expect `setGeneric` and `setGroupGeneric` create objects of class "genericFunction" and "groupGenericFunction" respectively.

**Slots**

- `.Data`: Object of class "function", the function definition of the generic, usually created automatically as a call to `standardGeneric`.
- `generic`: Object of class "character", the name of the generic function.
- `package`: Object of class "character", the name of the package to which the function definition belongs (and not necessarily where the generic function is stored). If the package is not specified explicitly in the call to `setGeneric`, it is usually the package on which the corresponding non-generic function exists.
- `group`: Object of class "list", the group or groups to which this generic function belongs. Empty by default.
- `valueClass`: Object of class "character"; if not an empty character vector, identifies one or more classes. It is asserted that all methods for this function return objects from these class (or from classes that extend them).
- `signature`: Object of class "character", the vector of formal argument names that can appear in the signature of methods for this generic function. By default, it is all the formal arguments, except for .... Order matters for efficiency: the most commonly used arguments in specifying methods should come first.
- `default`: Object of class "optionalMethod" (a union of classes "function" and "NULL"), containing the default method for this function if any. Generated automatically and used to initialize method dispatch.
- `skeleton`: Object of class "call", a slot used internally in method dispatch. Don’t expect to use it directly.

**Extends**

Class "function", from data part.  
Class "OptionalMethods", by class "function".  
Class "PossibleMethod", by class "function".
Methods

Generic function objects are used in the creation and dispatch of formal methods; information from the object is used to create methods list objects and to merge or update the existing methods for this generic.

Description

The functions documented here manage collections of methods associated with a generic function, as well as providing information about the generic functions themselves.

Usage

isGeneric(f, where, fdef, getName = FALSE)
isGroup(f, where, fdef)
removeGeneric(f, where)

dumpMethod(f, signature, file, where, def)
findFirst(f, generic = TRUE, where = topoenv(parent.frame()))
dumpMethods(f, file, signature, methods, where)
signature(...)

removeMethods(f, where = topoenv(parent.frame()), all = missing(where))

setReplaceMethod(f, ..., where = topoenv(parent.frame()))

generics(where, searchForm = FALSE)

Arguments

f
The character string naming the function.

where
The environment, namespace, or search-list position from which to search for objects. By default, start at the top-level environment of the calling function, typically the global environment (i.e., use the search list), or the namespace of a package from which the call came. It is important to supply this argument when calling any of these functions indirectly. With package namespaces, the default is likely to be wrong in such calls.

signature
The class signature of the relevant method. A signature is a named or unnamed vector of character strings. If named, the names must be formal argument names for the generic function. Signatures are matched to the arguments specified in the signature slot of the generic function (see the Details section of the setMethod documentation).

The signature argument to dumpMethods is ignored (it was used internally in previous implementations).

file
The file or connection on which to dump method definitions.

def
The function object defining the method; if omitted, the current method definition corresponding to the signature.
Named or unnamed arguments to form a signature.

**generic**
In testing or finding functions, should generic functions be included. Supply as `FALSE` to get only non-generic functions.

**fdef**
Optional, the generic function definition. Usually omitted in calls to `isGeneric`

**getName**
If `TRUE`, `isGeneric` returns the name of the generic. By default, it returns `TRUE`.

**methods**
The methods object containing the methods to be dumped. By default, the methods defined for this generic (optionally on the specified `where` location).

**all**
in `removeMethods`, logical indicating if all (default) or only the first method found should be removed.

**searchForm**
In `getGenerics`, if `TRUE`, the package slot of the returned result is in the form used by `search()`, otherwise as the simple package name (e.g., "package:base" vs "base").

### Summary of Functions

**isGeneric**: Is there a function named `f`, and if so, is it a generic?

The `getName` argument allows a function to find the name from a function definition. If it is `TRUE` then the name of the generic is returned, or `FALSE` if this is not a generic function definition.

The behavior of `isGeneric` and `getGeneric` for primitive functions is slightly different. These functions don't exist as formal function objects (for efficiency and historical reasons), regardless of whether methods have been defined for them. A call to `isGeneric` tells you whether methods have been defined for this primitive function, anywhere in the current search list, or in the specified position `where`. In contrast, a call to `getGeneric` will return what the generic for that function would be, even if no methods have been currently defined for it.

**removeGeneric, removeMethods**: Remove all the methods for the generic function of this name.

In addition, `removeGeneric` removes the function itself; `removeMethods` restores the non-generic function which was the default method. If there was no default method, `removeMethods` leaves a generic function with no methods.

**standardGeneric**: Dispatches a method from the current function call for the generic function `f`. It is an error to call `standardGeneric` anywhere except in the body of the corresponding generic function.

Note that `standardGeneric` is a primitive function in the `base` package for efficiency reasons, but rather documented here where it belongs naturally.

**dumpMethod**: Dump the method for this generic function and signature.

**findFunction**: return a list of either the positions on the search list, or the current top-level environment, on which a function object for `name` exists. The returned value is always a list, use the first element to access the first visible version of the function. See the example.

*NOTE*: Use this rather than `find` with `mode="function"`, which is not as meaningful, and has a few subtle bugs from its use of regular expressions. Also, `findFunction` works correctly in the code for a package when attaching the package via a call to `library`.

**dumpMethods**: Dump all the methods for this generic.

**signature**: Returns a named list of classes to be matched to arguments of a generic function.

**getGenerics**: returns the names of the generic functions that have methods defined on `where`; this argument can be an environment or an index into the search list. By default, the whole search list is used.
The methods definitions are stored with package qualifiers; for example, methods for function "initialize" might refer to two different functions of that name, on different packages. The package names corresponding to the method list object are contained in the slot package of the returned object. The form of the returned name can be plain (e.g., "base"), or in the form used in the search list ("package:base") according to the value of searchForm.

Details

isGeneric: If the fdef argument is supplied, take this as the definition of the generic, and test whether it is really a generic, with f as the name of the generic. (This argument is not available in S-Plus.)

removeGeneric: If where supplied, just remove the version on this element of the search list; otherwise, removes the first version encountered.

standardGeneric: Generic functions should usually have a call to standardGeneric as their entire body. They can, however, do any other computations as well. The usual setGeneric (directly or through calling setMethod) creates a function with a call to standardGeneric.

dumpMethod: The resulting source file will recreate the method.

dumpMethods: If signature is supplied only the methods matching this initial signature are dumped. (This feature is not found in S-Plus: don’t use it if you want compatibility.)

signature: The advantage of using signature is to provide a check on which arguments you meant, as well as clearer documentation in your method specification. In addition, signature checks that each of the elements is a single character string.

removeMethods: Returns TRUE if f was a generic function, FALSE (silently) otherwise.

If there is a default method, the function will be re-assigned as a simple function with this definition. Otherwise, the generic function remains but with no methods (so any call to it will generate an error). In either case, a following call to setMethod will consistently re-establish the same generic function as before.

setMethod("plot", "B", function(x,y,...){ cat("B ...\n") })
dumpMethods("plot", file=tmp)
stopifnot(removeMethod("plot", "A"), removeMethod("plot", "B"))
source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"),
  is(getMethod("plot", "B"), "MethodDefinition"))

---

**getClass**  
*Get Class Definition*

---

### Description

Get the definition of a class.

### Usage

```
getClass  (Class, .Force = FALSE, where)
getClassDef(Class, where, package, inherits = TRUE)
```

Arguments

Class  the character-string name of the class, often with a "package" attribute as noted below under package.

.Force  if TRUE, return NULL if the class is undefined; otherwise, an undefined class results in an error.

where  environment from which to begin the search for the definition; by default, start at the top-level (global) environment and proceed through the search list.

package  the name of the package asserted to hold the definition. If it is a non-empty string it is used instead of where, as the first place to look for the class. Note that the package must be loaded but need not be attached. By default, the package attribute of the Class argument is used, if any. There will usually be a package attribute if Class comes from class(x) for some object.

inherits  logical; should the class definition be retrieved from any enclosing environment and also from the cache? If FALSE only a definition in the environment where will be returned.

Details

Class definitions are stored in metadata objects in a package namespace or other environment where they are defined. When packages are loaded, the class definitions in the package are cached in an internal table. Therefore, most calls to getClassDef will find the class in the cache or fail to find it at all, unless inherits is FALSE, in which case only the environment(s) defined by package or where are searched.

The class cache allows for multiple definitions of the same class name in separate environments, with of course the limitation that the package attribute or package name must be provided in the call to

Value

The object defining the class. If the class definition is not found, getClassDef returns NULL, while getClass, which calls getClassDef, either generates an error or, if .Force is TRUE, returns a simple definition for the class. The latter case is used internally, but is not typically sensible in user code.

The non-null returned value is an object of class classRepresentation.

Use functions such as setClass and setClassUnion to create class definitions.

classRepresentation, setClass, isClass.

Examples

gtclass("numeric")  # a built in class

cld <- getClass("thisIsAnUndefinedClass", .force = TRUE)
cld  # a NULL prototype

# If you are really curious:
getMethod

## Get or Test for the Definition of a Method

**Description**

The function `selectMethod()` returns the method that would be selected for a call to function `f` if the arguments had classes as specified by `signature`. Failing to find a method is an error, unless argument `optional = TRUE`, in which case `NULL` is returned.

The function `findMethod()` returns a list of environments that contain a method for the specified function and `signature`; by default, these are a subset of the packages in the current search list. See section “Using `findMethod()`” for details.

The function `getMethod()` returns the method corresponding to the function and `signature` supplied similarly to `selectMethod`, but without using inheritance or group generics.

The functions `hasMethod()` and `existsMethod()` test whether `selectMethod()` or `getMethod()`, respectively, finds a matching method.

**Usage**

```r
selectMethod(f, signature, optional = FALSE, useInherited = ,
             mlist = , fdef = , verbose = , doCache = )
```

```r
findMethod(f, signature, where)
```

```r
getMethod(f, signature = character(), where, optional = FALSE,
           mlist, fdef)
```

```r
existsMethod(f, signature = character(), where)
```

```r
hasMethod(f, signature = character(), where)
```

**Arguments**

- `f` a generic function or the character-string name of one.
- `signature` the signature of classes to match to the arguments of `f`. See the details below.
- `where` the environment in which to look for the method(s). By default, if the call comes from the command line, the table of methods defined in the generic function itself is used, except for `findMethod` (see the section below).
- `optional` if the selection in `selectMethod` does not find a valid method an error is generated, unless `optional` is `TRUE`, in which case the value returned is `NULL`.
- `mlist, fdef, useInherited, verbose, doCache` optional arguments to `getMethod` and `selectMethod` for internal use. Avoid these: some will work as expected and others will not, and none of them is required for normal use of the functions. But see the section “Methods for `as()`” for nonstandard inheritance.
Details

The signature argument specifies classes, corresponding to formal arguments of the generic function; to be precise, to the signature slot of the generic function object. The argument may be a vector of strings identifying classes, and may be named or not. Names, if supplied, match the names of those formal arguments included in the signature of the generic. That signature is normally all the arguments except .... However, generic functions can be specified with only a subset of the arguments permitted, or with the signature taking the arguments in a different order.

It's a good idea to name the arguments in the signature to avoid confusion, if you're dealing with a generic that does something special with its signature. In any case, the elements of the signature are matched to the formal signature by the same rules used in matching arguments in function calls (see `match.call`).

The strings in the signature may be class names, "missing" or "ANY". See Methods_Details for the meaning of these in method selection. Arguments not supplied in the signature implicitly correspond to class "ANY"; in particular, giving an empty signature means to look for the default method.

A call to `getMethod` returns the method for a particular function and signature. The search for the method makes no use of inheritance.

The function `selectMethod` also looks for a method given the function and signature, but makes full use of the method dispatch mechanism; i.e., inherited methods and group generics are taken into account just as they would be in dispatching a method for the corresponding signature, with the one exception that conditional inheritance is not used. Like `getMethod`, `selectMethod` returns `NULL` or generates an error if the method is not found, depending on the argument `optional`.

Both `selectMethod` and `getMethod` will normally use the current version of the generic function in the R session, which has a table of the methods obtained from all the packages loaded in the session. Optional arguments can cause a search for the generic function from a specified environment, but this is rarely a useful idea. In contrast, `findMethod` has a different default and the optional `where=` argument may be needed. See the section “Using `findMethod()`”.

The functions `existsMethod` and `hasMethod` return `TRUE` or `FALSE` according to whether a method is found, the first corresponding to `getMethod` (no inheritance) and the second to `selectMethod`.

Value

The call to `selectMethod` or `getMethod` returns the selected method, if one is found. (This class extends function, so you can use the result directly as a function if that is what you want.) Otherwise an error is thrown if `optional` is `FALSE` and `NULL` is returned if `optional` is `TRUE`.

The returned method object is a `MethodDefinition` object, except that the default method for a primitive function is required to be the primitive itself. Note therefore that the only reliable test that the search failed is `is.null()`.

The returned value of `findMethod` is a list of environments in which a corresponding method was found; that is, a table of methods including the one specified.

Using `findMethod()`

As its name suggests, this function is intended to behave like `find`, which produces a list of the packages on the current search list which have, and have exported, the object named. That's what `findMethod` does also, by default. The "exported" part in this case means that the package's namespace has an `exportMethods` directive for this generic function.

An important distinction is that the absence of such a directive does not prevent methods from the package from being called once the package is loaded. Otherwise, the code in the package could not use un-exported methods.
So, if your question is whether loading package thisPkg will define a method for this function and signature, you need to ask that question about the namespace of the package:

```r
findMethod(f, signature, where = asNamespace("thisPkg"))
```

If the package did not export the method, attaching it and calling `findMethod` with no where argument will not find the method.

Notice also that the length of the signature must be what the corresponding package used. If thisPkg had only methods for one argument, only length-1 signatures will match (no trailing "ANY"), even if another currently loaded package had signatures with more arguments.

### Methods for as()

The function `setAs` allows packages to define methods for coercing one class of objects to another class. This works internally by defining methods for the generic function `coerce(from, to)`, which can not be called directly.

The R evaluator selects methods for this purpose using a different form of inheritance. While methods can be inherited for the object being coerced, they cannot inherit for the target class, since the result would not be a valid object from that class. If you want to examine the selection procedure, you must supply the optional argument `useInherited = c(TRUE, FALSE)` to `selectMethod`.

`Methods_Details` for the details of method selection; `GenericFunctions` for other functions manipulating methods and generic function objects; `MethodDefinition` for the class that represents method definitions.

### Examples

```r
testFun <- function(x)x
setGeneric("testFun")
setMethod("testFun", "numeric", function(x)x+1)

hasMethod("testFun", "numeric") # TRUE

hasMethod("testFun", "integer") # TRUE, inherited

existsMethod("testFun", "integer") # FALSE

hasMethod("testFun") # TRUE, default method

hasMethod("testFun", "ANY")
```
getPackageName

The Name associated with a Given Package

Description

The functions below produce the package associated with a particular environment or position on the search list, or of the package containing a particular function. They are primarily used to support computations that need to differentiate objects on multiple packages.

Usage

getPackageName(where, create = TRUE)
setPackageName(pkg, env)

packageSlot(object)
packageSlot(object) <- value

Arguments

where
the environment or position on the search list associated with the desired package.

object
object providing a character string name, plus the package in which this object is to be found.

value
the name of the package.

create
flag, should a package name be created if none can be inferred? If TRUE and no non-empty package name is found, the current date and time are used as a package name, and a warning is issued. The created name is stored in the environment if that environment is not locked.

pkg, env
make the string in pkg the internal package name for all computations that set class and method definitions in environment env.

Details

Package names are normally installed during loading of the package, by the INSTALL script or by the library function. (Currently, the name is stored as the object .packageName but don’t trust this for the future.)

Value

getPackageName returns the character-string name of the package (without the extraneous "package:" found in the search list).

packageSlot returns or sets the package name slot (currently an attribute, not a formal slot, but this may change someday).

setPackageName can be used to establish a package name in an environment that would otherwise not have one. This allows you to create classes and/or methods in an arbitrary environment, but it is usually preferable to create packages by the standard R programming tools (package.skeleton, etc.)
## hasArg

### Description

Returns TRUE if name corresponds to an argument in the call, either a formal argument to the function, or a component of . . . , and FALSE otherwise.

### Usage

```r
hasArg(name)
```

### Arguments

- **name**
  
  The name of a potential argument, as an unquoted name or character string.

### Details

The expression `hasArg(x)`, for example, is similar to `!missing(x)`, with two exceptions. First, `hasArg` will look for an argument named `x` in the call if `x` is not a formal argument to the calling function, but . . . is. Second, `hasArg` never generates an error if given a name as an argument, whereas `missing(x)` generates an error if `x` is not a formal argument.

### Value

Always TRUE or FALSE as described above.

### See Also

`missing`

### Examples

```r
ftest <- function(x1, ...) c(hasArg(x1), hasArg("y2"))

ftest(1)  ## c(TRUE, FALSE)
ftest(1, 2)  ## c(TRUE, FALSE)
ftest(y2 = 2)  ## c(FALSE, TRUE)
ftest(y = 2)  ## c(FALSE, FALSE) (no partial matching)
ftest(y2 = 2, x = 1)  ## c(TRUE, TRUE) partial match x1
```
The implicit generic mechanism stores generic versions of functions in a table in a package. The package does not want the current version of the function to be a generic, however, and retains the non-generic version.

When a call to `setMethod` or `setGeneric` creates a generic version for one of these functions, the object in the table is used. This mechanism is only needed if special arguments were used to create the generic: e.g., the `signature` or the `valueClass` options.

Function `implicitGeneric()` returns the implicit generic version, `setGenericImplicit()` turns a generic implicit, `prohibitGeneric()` prevents your function from being made generic, and `registerImplicitGenerics()` saves a set of implicit generic definitions in the cached table of the current session.

### Usage

- `implicitGeneric(name, where, generic)`
- `setGenericImplicit(name, where, restore = TRUE)`
- `prohibitGeneric(name, where)`
- `registerImplicitGenerics(what, where)`

### Arguments

- **name**: Character string name of the function.
- **where**: Package or environment in which to register the implicit generics. When using the functions from the top level of your own package source, this argument should be omitted.
- **generic**: Obsolete, and likely to be deprecated.
- **restore**: Should the non-generic version of the function be restored?.
- **what**: Optional table of the implicit generics to register, but nearly always omitted, when it defaults to a standard metadata name.

### Details

Multiple packages may define methods for the same function, to apply to classes defined in that package. Arithmetic and other operators, `plot()` and many other basic computations are typical examples. It’s essential that all such packages write methods for the same definition of the generic function. So long as that generic uses the default choice for signature and other parameters, nothing needs to be done.

If the generic has special properties, these need to be ensured for all packages creating methods for it. The simplest solution is just to make the function generic in the package that originally owned it. If for some reason the owner(s) of that package are unwilling to do this, the alternative is to define the correct generic, save it in a special table and restore the non-generic version by calling `setGenericImplicit`.

Note that the package containing the function can define methods for the implicit generic as well; when the implicit generic is made a real generic, those methods will be included.
The usual reason for having a non-default implicit generic is to provide a non-default signature, and the usual reason for that is to allow lazy evaluation of some arguments. All arguments in the signature of a generic function must be evaluated at the time the function needs to select a method. In the base function `with()` in the example below, evaluation of the argument `expr` must be delayed; therefore, it is excluded from the signature.

If you want to completely prohibit anyone from turning your function into a generic, call `prohibitGeneric()`.

Function `implicitGeneric()` returns the implicit generic version of the named function. If there is no table of these or if this function is not in the table, the result of a simple call `setGeneric(name)` is returned.

**Value**

Function `implicitGeneric()` returns the implicit generic definition (and caches that definition the first time if it has to construct it).

The other functions exist for their side effect and return nothing useful.

**Implicit Generics for Base Functions**

Implicit generic versions exist for some functions in the packages supplied in the distribution of R itself. These are stored in the ‘methods’ package itself and will always be available.

As emphasized repeatedly in the documentation, `setGeneric()` calls for a function in another package should never have non-default settings for arguments such as `signature`. The reasoning applies specially to functions in supplied packages, since methods for these are likely to exist in multiple packages. A call to `implicitGeneric()` will show the generic version.

**See Also**

`setGeneric`

**Examples**

```r
### How we would make the function with() into a generic:

## Since the second argument, 'expr' is used literally, we want
## with() to only have "data" in the signature.

## Not run:
setGeneric("with", signature = "data")
## Now we could predefine methods for "with" if we wanted to.

## When ready, we store the generic as implicit, and restore the original
setGenericImplicit("with")

## End(Not run)

implicitGeneric("with")

# (This implicit generic is stored in the 'methods' package.)
```
inheritedSlotNames  
Names of Slots Inherited From a Super Class

Description
For a class (or class definition, see getClass and the description of class classRepresentation), give the names which are inherited from “above”, i.e., super classes, rather than by this class’ definition itself.

Usage
inheritedSlotNames(Class, where = topenv(parent.frame()))

Arguments
Class character string or classRepresentation, i.e., resulting from getClass.
where environment, to be passed further to isClass and getClass.

Value
text character vector of slot names, or NULL.

See Also
slotNames, slot, setClass, etc.

Examples
.srch <- search()
library(stats4)
inheritedSlotNames("mle")

if(require("Matrix")) {
  print( inheritedSlotNames("Matrix") ) # NULL
  ## whereas
  print( inheritedSlotNames("sparseMatrix") ) # --> Dim & Dimnames
  ## i.e. inherited from "Matrix" class

  print( cl <- getClass("dgCMatrix") ) # six slots, etc

  print( inheritedSlotNames(cl) ) # *all* six slots are inherited
  ## Not run:

  ## detach package we've attached above:
  for(n in rev(which(is.na(match(search(), .srch)))))
    try( detach(pos = n) )

  ## End(Not run)
Methods to Initialize New Objects from a Class

Description
The arguments to function `new` to create an object from a particular class can be interpreted specially for that class, by the definition of a method for function `initialize` for the class. This documentation describes some existing methods, and also outlines how to write new ones.

Methods

signature(.Object = "ANY") The default method for `initialize` takes either named or unnamed arguments. Argument names must be the names of slots in this class definition, and the corresponding arguments must be valid objects for the slot (that is, have the same class as specified for the slot, or some superclass of that class). If the object comes from a superclass, it is not coerced strictly, so normally it will retain its current class (specifically, `as.object, Class, strict = FALSE`).

Unnamed arguments must be objects of this class, of one of its superclasses, or one of its subclasses (from the class, from a class this class extends, or from a class that extends this class). If the object is from a superclass, this normally defines some of the slots in the object. If the object is from a subclass, the new object is that argument, coerced to the current class.

Unnamed arguments are processed first, in the order they appear. Then named arguments are processed. Therefore, explicit values for slots always override any values inferred from superclass or subclass arguments.

signature(.Object = "traceable") Objects of a class that extends `traceable` are used to implement debug tracing (see class `traceable` and `trace`).

The `initialize` method for these classes takes special arguments `def, tracer, exit, at, print`. The first of these is the object to use as the original definition (e.g., a function). The others correspond to the arguments to `trace`.

signature(.Object = "environment"), signature(.Object = ".environment") The `initialize` method for environments takes a named list of objects to be used to initialize the environment. Subclasses of "environment" inherit an `initialize` method through ".environment", which has the additional effect of allocating a new environment. If you define your own method for such a subclass, be sure either to call the existing method via `callNextMethod` or allocate an environment in your method, since environments are references and are not duplicated automatically.

signature(.Object = "signature") This is a method for internal use only. It takes an optional `functionDef` argument to provide a generic function with a `signature` slot to define the argument names. See `Methods_Details` for details.

Writing Initialization Methods

Initialization methods provide a general mechanism corresponding to generator functions in other languages.

The arguments to `initialize` are `.Object` and `...`. Nearly always, `initialize` is called from `new`, not directly. The `.Object` argument is then the prototype object from the class.

Two techniques are often appropriate for `initialize` methods: special argument names and `callNextMethod`. 
You may want argument names that are more natural to your users than the (default) slot names. These will be the formal arguments to your method definition, in addition to .Object (always) and ...(optionally). For example, the method for class "traceable" documented above would be created by a call to setMethod of the form:

```r
setMethod("initialize", "traceable",
  function(.Object, def, tracer, exit, at, print) ...)
```

In this example, no other arguments are meaningful, and the resulting method will throw an error if other names are supplied.

When your new class extends another class, you may want to call the initialize method for this superclass (either a special method or the default). For example, suppose you want to define a method for your class, with special argument x, but you also want users to be able to set slots specifically. If you want x to override the slot information, the beginning of your method definition might look something like this:

```r
function(.Object, x, ...) {
  Object <- callNextMethod(.Object, ...)
  if(!missing(x)) { # do something with x
```

You could also choose to have the inherited method override, by first interpreting x, and then calling the next method.

---

**Description**

The majority of applications using methods and classes will be in R packages implementing new computations for an application, using new classes of objects that represent the data and results. Computations will be implemented using methods that implement functional computations when one or more of the arguments is an object from these classes.

Calls to the functions `setClass()` define the new classes; calls to `setMethod` define the methods. These, along with ordinary R computations, are sufficient to get started for most applications.

Classes are defined in terms of the data in them and what other classes of data they inherit from. Section ‘Defining Classes’ outlines the basic design of new classes.

Methods are R functions, often implementing basic computations as they apply to the new classes of objects. Section ‘Defining Methods’ discusses basic requirements and special tools for defining methods.

The classes discussed here are the original functional classes. R also supports formal classes and methods similar to those in other languages such as Python, in which methods are part of class definitions and invoked on an object. These are more appropriate when computations expect references to objects that are persistent, making changes to the object over time. See ReferenceClasses and Chapter 9 of the reference for the choice between these and S4 classes.
Defining Classes

All objects in \( \mathbb{R} \) belong to a class; ordinary vectors and other basic objects are built-in (builtin-class). A new class is defined in terms of the named slots that it has and/or in terms of existing classes that it inherits from, or contains (discussed in 'Class Inheritance' below). A call to \texttt{setClass()} names a new class and uses the corresponding arguments to define it.

For example, suppose we want a class of objects to represent a collection of positions, perhaps from GPS readings. A natural way to think of these in \( \mathbb{R} \) would have vectors of numeric values for latitude, longitude and altitude. A class with three corresponding slots could be defined by:

\[ \text{Pos} \leftarrow \text{setClass("Pos", slots = c(latitude = "numeric", longitude = "numeric", altitude = "numeric"))} \]

The value returned is a function, typically assigned as here with the name of the class. Calling this function returns an object from the class; its arguments are named with the slot names. If a function in the class had read the corresponding data, perhaps from a CSV file or from a data base, it could return an object from the class by:

\[ \text{Pos(latitude = x, longitude = y, altitude = z)} \]

The slots are accessed by the \texttt{@} operator; for example, if \( g \) is an object from the class, \( g@\text{latitude} \).

In addition to returning a generator function the call to \texttt{setClass()} assigns a definition of the class in a special metadata object in the package’s namespace. When the package is loaded into an \( \mathbb{R} \) session, the class definition is added to a table of known classes.

To make the class and the generating function publicly available, the package should include \texttt{POS} in \texttt{exportClasses()} and \texttt{export()} directives in its \texttt{NAMESPACE} file:

\[ \text{exportClasses(POS); export(POS)} \]

Defining Methods

Defining methods for an \( \mathbb{R} \) function makes that function generic. Instead of a call to the function always being carried out by the same method, there will be several alternatives. These are selected by matching the classes of the arguments in the call to a table in the generic function, indexed by classes for one or more formal arguments to the function, known as the signatures for the methods.

A method definition then specifies three things: the name of the function, the signature and the method definition itself. The definition must be a function with the same formal arguments as the generic.

For example, a method to make a plot of an object from class "Pos" could be defined by:

\[ \text{setMethod("plot", c("Pos", "missing"), function(x, y, ...) \{} \text{plotPos(x, y) \}} \]

This method will match a call to \texttt{plot()} if the first argument is from class "Pos" or a subclass of that. The second argument must be missing; only a missing argument matches that class in the signature. Any object will match class "ANY" in the corresponding position of the signature.

Class Inheritance

A class may inherit all the slots and methods of one or more existing classes by specifying the names of the inherited classes in the \texttt{contains} = argument to \texttt{setClass()}.

To define a class that extends class "Pos" to a class "GPS" with a slot for the observation times:

\[ \text{GPS} \leftarrow \text{setClass("GPS", slots = c(time = "POSIXt"), contains = "Pos")} \]

The inherited classes may be S4 classes, S3 classes or basic data types. S3 classes need to be identified as such by a call to \texttt{setOldClass()}; most S3 classes in the base package and many in the other built-in packages are already declared, as is "POSIXt". If it had not been, the application package should contain:
Inheriting from one of the R types is special. Objects from the new class will have the same type. A class `Currency` that contains numeric data plus a slot "unit" would be created by

```
Currency <- setClass("Currency", slots = c(unit = "character"), contains = "numeric")
```

Objects created from this class will have type "numeric" and inherit all the built-in arithmetic and other computations for that type. Classes can only inherit from at most one such type; if the class does not inherit from a type, objects from the class will have type "S4".

References

**SClassExtension.** Of the information in these objects, one piece can be useful: the number of generations between the classes, given by the "distance" slot.

Programming with the result of the call to `extends`, particularly using `sapply`, can select superclasses. The programming technique is to define a test function that returns TRUE for superclasses or relationships obeying some requirement. For example, to find only next-to-direct superclasses, use this function with the list of extension objects:

```r
function(what) is(what, "SClassExtension") && what@distance == 2
```

or, to find only superclasses from "myPkg", use this function with the simple vector of names:

```r
function(what) getClassDef(what)@package == "myPkg"
```

Giving such functions as an argument to `sapply` called on the output of `extends` allows you to find superclasses with desired properties. See the examples below.

Note that the function using extension objects must test the class of its argument since, unfortunately for this purpose, the list returned by `extends` includes class1 itself, as the object TRUE.

**References**

**See Also**

Although `inherits` is defined for S3 classes, it has been modified so that the result returned is nearly always equivalent to `is`, both for S4 and non-S4 objects. Since it is implemented in C, it is somewhat faster. The only non-equivalences arise from use of `setIs`, which should rarely be encountered.

**Examples**

```r
## Not run:
## this example can be run if package XRPython from CRAN is installed.
supers <- extends("PythonInterface")
## find all the superclasses from package XR
fromXR <- sapply(supers,
    function(what) getClassDef(what)@package == "XR")
## print them
supers[fromXR]

## find all the superclasses at distance 2
superRelations <- extends("PythonInterface", fullInfo = TRUE)
dist2 <- sapply(superRelations,
    function(what) is(what, "SClassExtension") && what@distance == 2)
## print them
names(superRelations)[dist2]

## End(Not run)
```
isSealedMethod

*Check for a Sealed Method or Class*

**Description**

These functions check for either a method or a class that has been sealed when it was defined, and which therefore cannot be re-defined.

**Usage**

```
isSealedMethod(f, signature, fdef, where)
isSealedClass(Class, where)
```

**Arguments**

- `f` The quoted name of the generic function.
- `signature` The class names in the method’s signature, as they would be supplied to `setMethod`.
- `fdef` Optional, and usually omitted: the generic function definition for `f`.
- `Class` The quoted name of the class.
- `where` where to search for the method or class definition. By default, searches from the top environment of the call to `isSealedMethod` or `isSealedClass`, typically the global environment or the namespace of a package containing a call to one of the functions.

**Details**

In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if one of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the sealed argument to `setClass` or `setMethod`.

**Value**

The functions return `FALSE` if the method or class is not sealed (including the case that it is not defined); `TRUE` if it is.

**References**

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)
Examples

```r
## these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track", slots = c(x="numeric", y="numeric"))
## but this is FALSE
isSealedClass("track")
## and so is this
isSealedClass("A Name for an undefined Class")
## and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```

Description

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as `quote`.

Usage

```r
### each of these classes corresponds to an unevaluated object
### in the S language.
### The class name can appear in method signatures,
### and in a few other contexts (such as some calls to `as()`).

"("  
"<-"  
"call"  
"for"  
"if"  
"repeat"  
"while"  
"name"  
"{

### Each of the classes above extends the virtual class "language"
```

Objects from the Class

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to `new(Class, ...), where Class is the quoted class name, and the ...arguments are either empty or a single object that is from this class (or an extension).
LinearMethodsList-class

Methods

**coerce** signature(from = "ANY", to = "call"). A method exists for as(object, "call"), calling as.call().

Examples

```
showClass("language")

is(quote(sin(x))) # "call" "language"
```

```
(ff <- new("if")); is(ff) # "if" "language"
(ff <- new("for")); is(ff) # "for" "language"
```

LinearMethodsList-class

Class "LinearMethodsList"

Description

A version of methods lists that has been ‘linearized’ for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.

Objects from the Class

The function `linearizeMlist` converts an ordinary methods list object into the linearized form.

Slots

- **methods**: Object of class "list", the method definitions.
- **arguments**: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.
- **classes**: Object of class "list", the corresponding classes in the signatures.
- **generic**: Object of class "genericFunction"; the generic function to which the methods correspond.

Future Note

The current version of `linearizeMlist` does not take advantage of the `MethodDefinition` class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don’t write code depending precisely on the present form, although all the current information will be obtainable in the future.

See Also

Function `linearizeMlist` for the computation, and class `MethodsList` for the original, recursive form.
LocalReferenceClasses  Localized Objects based on Reference Classes

Description

Local reference classes are modified ReferenceClasses that isolate the objects to the local frame. Therefore, they do not propagate changes back to the calling environment. At the same time, they use the reference field semantics locally, avoiding the automatic duplication applied to standard R objects.

The current implementation has no special construction. To create a local reference class, call `setRefClass()` with a `contains=` argument that includes "localRefClass". See the example below.

Local reference classes operate essentially as do regular, functional classes in R; that is, changes are made by assignment and take place in the local frame. The essential difference is that replacement operations (like the change to the `twiddle` field in the example) do not cause duplication of the entire object, as would be the case for a formal class or for data with attributes or in a named list. The purpose is to allow large objects in some fields that are not changed along with potentially frequent changes to other fields, but without copying the large fields.

Usage

```r
setRefClass(Class, fields = , contains = c("localRefClass",....),
            methods =, where =, ...)
```

Details

Localization of objects is only partially automated in the current implementation. Replacement expressions using the `$<-$` operator are safe.

However, if reference methods for the class themselves modify fields, using `<<-`, for example, then one must ensure that the object is local to the relevant frame before any such method is called. Otherwise, standard reference class behavior still prevails.

There are two ways to ensure locality. The direct way is to invoke the special method `x$ensureLocal()` on the object. The other way is to modify a field explicitly by `x$field <- ...`. It's only necessary that one or the other of these happens once for each object, in order to trigger the shallow copy that provides locality for the references. In the example below, we show both mechanisms.

However it's done, localization must occur before any methods make changes. (Eventually, some use of code tools should at least largely automate this process, although it may be difficult to guarantee success under arbitrary circumstances.)

Author(s)

John Chambers

Examples

```r
## class "myIter" has a BigData field for the real (big) data
## and a "twiddle" field for some parameters that it twiddles
## ( for some reason)
```
myIter <- setRefClass("myIter", contains = "localRefClass",
    fields = list(BigData = "numeric", twiddle = "numeric"))

tw <- rnorm(3)
x1 <- myIter(BigData = rnorm(1000), twiddle = tw) # OK, not REALLY big

twiddler <- function(x, n) {
    x$ensureLocal() # see the Details. Not really needed in this example
    for(i in seq(length = n)) {
        x$twiddle <- x$twiddle + rnorm(length(x$twiddle))
        ## then do something ....
        ## Snooping in gdb, etc will show that x$BigData is not copied
    }
    return(x)
}

x2 <- twiddler(x1, 10)
stopifnot(identical(x1$twiddle, tw), !identical(x1$twiddle, x2$twiddle))

"makeClassRepresentation"

Create a Class Definition

Description

Constructs an object of class classRepresentation to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as setClass would do.

Usage

makeClassRepresentation(name, slots=list(), superClasses=character(),
    prototype=NULL, package, validity, access,
    version, sealed, virtual=NA, where)

Arguments

name character string name for the class
slots named list of slot classes as would be supplied to setClass, but without the unnamed arguments for superClasses if any.
superClasses what classes does this class extend
prototype an object providing the default data for the class, e.g., the result of a call to prototype.
package The character string name for the package in which the class will be stored; see getPackageName.
validity Optional validity method. See validObject, and the discussion of validity methods in the reference.
access Access information. Not currently used.
version Optional version key for version control. Currently generated, but not used.
method.skeleton

sealed Is the class sealed? See setClass.
virtual Is this known to be a virtual class?
where The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under GenericFunctions.

See Also

setClass

Description

This function writes a source file containing a call to setMethod to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

Usage

method.skeleton(generic, signature, file, external = FALSE, where)

Arguments

generic the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to setMethod.
signature the method signature, as it would be given to setMethod
file a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R". To write multiple method skeletons to one file, open the file connection first and then pass it to method.skeleton() in multiple calls.
external flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to setMethod. If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.
where The environment in which to look for the function; by default, the top-level environment of the call to method.skeleton.

Value

The file argument, invisibly, but the function is used for its side effect.
MethodDefinition-class

Classes to Represent Method Definitions

Description

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

Details

Method definition objects are functions with additional information defining how the function is being used as a method. The target slot is the class signature for which the method will be dispatched, and the defined slot the signature for which the method was originally specified (that is, the one that appeared in some call to setMethod).

Objects from the Class

The action of setting a method by a call to setMethod creates an object of this class. It's unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to setMethod with argument sealed = TRUE. It has the same representation as "MethodDefinition".

Slots

.Data: Object of class "function"; the data part of the definition.
target: Object of class "signature"; the signature for which the method was wanted.
defined: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to target.
generic: Object of class "character"; the function for which the method was created.

See Also

setMethod, package.skeleton

Examples

setClass("track", slots = c(x ="numeric", y="numeric"))
method.skeleton("show", "track")  ## writes show_track.R
method.skeleton("Ops", c("track", "track"))  ## writes "Ops_track_track.R"

## write multiple method skeletons to one file
con <- file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
close(con)

MethodsList-class

Class MethodsList, Defunct Representation of Methods

Description

This class of objects was used in the original implementation of the package to control method
dispatch. Its use is now defunct, but object appear as the default method slot in generic functions.
This and any other remaining uses will be removed in the future.

For the modern alternative, see listOfMethods.

The details in this documentation are retained to allow analysis of old-style objects.

Details

Suppose a function f has formal arguments x and y. The methods list object for that function has the
object as.name("x") as its argument slot. An element of the methods named "track" is selected
if the actual argument corresponding to x is an object of class "track". If there is such an element,
it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which x is of class "track".
In the second case, the new methods list object defines the available methods depending on the
remaining formal arguments, in this example, y.

Each method corresponds conceptually to a signature; that is a named list of classes, with
names corresponding to some or all of the formal arguments. In the previous example,
if selecting class "track" for x, finding that the selection was another methods list and
then selecting class "numeric" for y would produce a method associated with the signature
x = "track", y = "numeric".
Methods_Details

Slots

argument: Object of class "name". The name of the argument being used for dispatch at this level.

methods: A named list of the methods (and method lists) defined explicitly for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.

allMethods: A named list, contains all the directly defined methods from the methods slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see Methods_Details

Extends

Class "OptionalMethods", directly.

Methods_Details

General Information on Methods

Description

This documentation covers some general topics on how methods work and how the methods package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn’t work as expected.

For additional information see documentation for the important steps: (setMethod(), setClass(), and setGeneric()). Also Methods_for_Nongenerics on defining formal methods for functions that are not currently generic functions; Methods_for_S3 for the relation to S3 classes and methods; Classes_Details for class definitions and Chapters 9 and 10 of the reference.

How Methods Work

A call to a generic function selects a method matching the actual arguments in the call. The body of the method is evaluated in the frame of the call to the generic function. A generic function is identified by its name and by the package to which it correspond. Unlike ordinary functions, the generic has a slot that specifies its package.

In an R session, there is one version of each such generic, regardless of where the call to that generic originated, and the generic function has a table of all the methods currently available for it; that is, all the methods in packages currently loaded into the session.

Methods are frequently defined for functions that are non-generic in their original package, for example, for function plot() in package graphics. An identical version of the corresponding generic function may exist in several packages. All methods will be dispatched consistently from the R session.

Each R package with a call to setMethod in its source code will include a methods metadata object for that generic. When the package is loaded into an R session, the methods for each generic function are cached, that is, added to the environment of the generic function. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions (see GroupGenericFunctions) to find an applicable method. See the “Method Selection and Dispatch” section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these behave identically with respect to method selection.
In contrast, it is possible for the same function name to refer to more than one generic function, when these have different package slots. In the latter case, \texttt{R} considers the functions unrelated: A generic function is defined by the combination of name and package. See the “Generic Functions” section below.

The methods for a generic are stored according to the corresponding signature in the call to \texttt{setMethod} that defined the method. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the "signature" slot of the generic function itself. By default, the signature of the generic consists of all the formal arguments except \ldots, in the order they appear in the function definition.

Trailing arguments in the signature of the generic will be inactive if no method has yet been specified that included those arguments in its signature. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using lazy evaluation. Therefore, it’s important to exclude from the signature any arguments that need to be dealt with symbolically (such as the \texttt{expr} argument to function \texttt{function}). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing".

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.

**Method Selection: Details**

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of \texttt{class(x)} for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes. A method found by this search is cached in the generic function so that future calls with the same argument classes will not require repeating the search. In any likely application, the search for inherited methods will be a negligible overhead.

Each class definition may include a list of one or more direct superclasses of the new class. The simplest and most common specification is by the \texttt{contains=} argument in the call to \texttt{setClass}. Each class named in this argument is a superclass of the new class. A class will also have as a direct superclass any class union to which it is a member. Class unions are created by a call to \texttt{setClassUnion}. Additional members can be added to the union by a simple call to \texttt{setIs}. Superclasses specified by either mechanism are the direct superclasses.

Inheritance specified in either of these forms is simple in the sense that all the information needed for the superclass is asserted to be directly available from the object. \texttt{R} inherited from \texttt{S} a more general form of inheritance in which inheritance may require some transformation or be conditional on a test. This more general form has not proved to be useful in general practical situations. Since it also adds some computational costs non-simple inheritance is not recommended. See \texttt{setIs} for the general version.

The direct superclasses themselves may have direct superclasses and similarly through further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the \texttt{R} session. The distance between the two classes is defined to be the number of generations: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. To see all the superclasses, with their distance, print the class definition by calling
**Methods_Details**

*getClass*. In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.

When a method is to be selected by inheritance, a search is made in the table for all methods corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the recommended package Matrix). This class has (currently) three direct superclasses and through these additional superclasses at distances 2 through 4. A method that had been defined for any of these classes or for class "ANY" (the default method) would be eligible. Methods for the shortest difference are preferred. If there is only one best method in this sense, method selection is unambiguous.

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function `outer` generating an array of all possible combinations). The search now finds all the methods matching any of this combination of classes. For each argument, the distance to the superclass defines which method(s) are preferred for that argument. A method is considered best for selection if it is among the best (i.e., has the least distance) for each argument.

The end result is that zero, one or more methods may be “best”. If one, this method is selected and cached in the table of methods. If there is more than one best match, a message is printed noting which method was selected (the first method lexicographically in the ordering) and what other methods could have been selected. Since the ambiguity is usually nothing the end user could control, this is not a warning. Package authors should examine their package for possible ambiguous inheritance by calling `testInheritedMethods`.

Cached inherited selections are not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call `resetGeneric`. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function `selectMethod`. Note that some computations may use this function directly, with optional arguments. The prime example is the use of `coerce()` methods by function `as()`. There has been some confusion from comparing coerce methods to a call to `selectMethod` with other options.

**Method Evaluation: Details**

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will not have been evaluated, since method dispatch always uses class `missing` for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent ("enclosing") environment of the second context is the environment of the method as a function, so that all R programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the references in the sections indicated.
Generic Functions

In principle, a generic function could be any function that evaluates a call to standardGeneric(), the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class "function" also extend the class genericFunction. Such objects have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in R by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, R will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of R.

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

R distinguishes standard and nonstandard generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, implicit generic functions and the special computations required to deal with R’s primitive functions. Packages can contain a table of implicit generic versions of functions in the package, if the package wishes to leave a function non-generic but to constrain what the function would be like if it were generic. Such implicit generic functions are created during the installation of the package, essentially by defining the generic function and possibly methods for it, and then reverting the function to its non-generic form. (See implicitGeneric for how this is done.) The mechanism is mainly used for functions in the older packages in R, which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if something special has to be specified. All functions have a corresponding implicit generic version defined automatically (an implicit, implicit generic function one might say). This function is a standard generic with the same arguments as the non-generic function, with the non-generic version as the default (and only) method, and with the generic signature being all the formal arguments except ...

The implicit generic mechanism is needed only to override some aspect of the default definition. One reason to do so would be to remove some arguments from the signature. Arguments that may need to be interpreted literally, or for which the lazy evaluation mechanism of the language is needed, must not be included in the signature of the generic function, since all arguments in the signature will be evaluated in order to select a method. For example, the argument expr to the function with is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not suitable as the default method. Perhaps the function only applies to some classes of objects, and the package designer prefers to have no general default method. In the other direction, the package designer might have some ideas about suitable methods for some classes, if the function were generic. With reasonably modern packages, the simple approach in all these cases is just to define the function as a generic. The implicit generic mechanism is mainly attractive for older packages that do not want to require the methods package to be available.
Methods for Nongenerics

Generic functions will also be defined but not obviously visible for functions implemented as primitive functions in the base package. Primitive functions look like ordinary functions when printed but are in fact not function objects but objects of two types interpreted by the R evaluator to call underlying C code directly. Since their entire justification is efficiency, R refuses to hide primitives behind a generic function object. Methods may be defined for most primitives, and corresponding metadata objects will be created to store them. Calls to the primitive still go directly to the C code, which will sometimes check for applicable methods. The definition of “sometimes” is that methods must have been detected for the function in some package loaded in the session and isS4(x) is TRUE for the first argument (or for the second argument, in the case of binary operators). You can test whether methods have been detected by calling isGeneric for the relevant function and you can examine the generic function by calling getGeneric, whether or not methods have been detected. For more on generic functions, see the references and also section 2 of the R Internals document supplied with R.

Method Definitions

All method definitions are stored as objects from the MethodDefinition class. Like the class of generic functions, this class extends ordinary R functions with some additional slots: "generic", containing the name and package of the generic function, and two signature slots, "defined" and "target", the first being the signature supplied when the method was defined by a call to setMethod. The "target" slot starts off equal to the "defined" slot. When an inherited method is cached after being selected, as described above, a copy is made with the appropriate "target" signature. Output from showMethods, for example, includes both signatures.

Method definitions are required to have the same formal arguments as the generic function, since the method dispatch mechanism does not rematch arguments, for reasons of both efficiency and consistency.

Methods for Non-Generic Functions in Other Packages

Description

In writing methods for an R package, it’s common for these methods to apply to a function (in another package) that is not generic in that package; that is, there are no formal methods for the function in its own package, although it may have S3 methods. The programming in this case involves one extra step, to call setGeneric() to declare that the function is generic in your package. Calls to the function in your package will then use all methods defined there or in any other loaded package that creates the same generic function. Similarly, calls to the function in those packages will use your methods.
The original version, however, remains non-generic. Calls in that package or in other packages that use that version will not dispatch your methods except for special circumstances:

1. If the function is one of the primitive functions that accept methods, the internal C implementation will dispatch methods if one of the arguments is an S4 object, as should be the case.

2. If the other version of the function dispatches S3 methods and your methods are also registered as S3 methods, the method will usually be dispatched as that S3 method.

3. Otherwise, you will need to ensure that all calls to the function come from a package in which the function is generic, perhaps by copying code to your package.

Details and the underlying reasons are discussed in the following sections.

Generic and Non-Generic Calls

Creating methods for a function (any function) in a package means that calls to the function in that package will select methods according to the actual arguments. However, if the function was originally a non-generic in another package, calls to the function from that package will not dispatch methods. In addition, calls from any third package that imports the non-generic version will also not dispatch methods. This section considers the reason and how one might deal with the consequences.

The reason is simply the R namespace mechanism and its role in evaluating function calls. When a name (such as the name of a function) needs to be evaluated in a call to a function from some package, the evaluator looks first in the frame of the call, then in the namespace of the package and then in the imports to that package.

Defining methods for a function in a package ensures that calls to the function in that package will select the methods, because a generic version of the function is created in the namespace. Similarly, calls from another package that has or imports the generic version will select methods. Because the generic versions are identical, all methods will be available in all these packages.

However, calls from any package that imports the old version or just selects it from the search list will usually not select methods.

A an example, consider the function `data.frame()` in the base package. This function takes any number of objects as arguments and attempts to combine them as variables into a data frame object. It does this by calling `as.data.frame()`, also in the base package, for each of the objects.

A reasonable goal would be to extend the classes of objects that can be included in a data frame by defining methods for `as.data.frame()`. But calls to `data.frame()`, will still use the version of that function in the base package, which continues to call the non-generic `as.data.frame()` in that package.

The details of what happens and options for dealing with it depend on the form of the function: a primitive function; a function that dispatches S3 methods; or an ordinary R function.

Primitive functions are not actual R function objects. They go directly to internal C code. Some of them, however, have been implemented to recognize methods. These functions dispatch both S4 and S3 methods from the internal C code. There is no explicit generic function, either S3 or S4. The internal code looks for S4 methods if the first argument, or either of the arguments in the case of a binary operator, is an S4 object. If no S4 method is found, a search is made for an S3 method. So defining methods for these functions works as long as the relevant classes have been defined, which should always be the case.

A function dispatches S3 methods by calling `UseMethod()`, which does look for formal methods regardless of whether the first argument is an S4 object or not. This applies to the `as.data.frame()` example above. To have methods called in this situation, your package must also define the method as an S3 method, if possible. See section ‘S3 “Generic” Functions’.
In the third possibility, the function is defined with no expectation of methods. For example, the base package has a number of functions that compute numerical decompositions of matrix arguments. Some, such as `chol()` and `qr()` are implemented to dispatch S3 methods; others, such as `svd()` are implemented directly as a specific computation. A generic version of the latter functions can be written and called directly to define formal methods, but no code in another package that does not import this generic version will dispatch such methods.

In this case, you need to have the generic version used in all the indirect calls to the function supplying arguments that should dispatch methods. This may require supplying new functions that dispatch methods and then call the function they replace. For example, if S3 methods did not work for `as.data.frame()`, one could call a function that applied the generic version to all its arguments and then called `data.frame()` as a replacement for that function. If all else fails, it might be necessary to copy over the relevant functions so that they would find the generic versions.

S3 “Generic” Functions

S3 method dispatch looks at the class of the first argument. S3 methods are ordinary functions with the same arguments as the generic function. The “signature” of an S3 method is identified by the name to which the method is assigned, composed of the name of the generic function, followed by “.”, followed by the name of the class. For details, see `UseMethod`.

To implement a method for one of these functions corresponding to S4 classes, there are two possibilities: either an S4 method or an S3 method with the S4 class name. The S3 method is only possible if the intended signature has the first argument and nothing else. In this case, the recommended approach is to define the S3 method and also supply the identical function as the definition of the S4 method. If the S3 generic function was `f3(x, ...)` and the S4 class for the new method was "myClass":

```r
f3.myClass <- function(x, ...) { ..... }
setMethod("f3", "myClass", f3.myClass)
```

Defining both methods usually ensures that all calls to the original function will dispatch the intended method. The S4 method alone would not be called from other packages using the original version of the function. On the other hand, an S3 method alone will not be called if there is any eligible non-default S4 method.

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to `setOldClass`, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of `extends(class(x))` as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

An existing S3 method may not behave as desired for an S4 subclass, in which case utilities such as `asS3` and `S3Part` may be useful. If the S3 method fails on the S4 object, `asS3(x)` may be passed instead; if the object returned by the S3 method needs to be incorporated in the S4 object, the replacement function for `S3Part` may be useful.

See Also

*Methods_for_S3* for suggested implementation of methods that work for both S3 and S4 dispatch.
Examples

A class that extends a registered S3 class inherits that class’ S3 methods.

```
setClass("myFrame", contains = "data.frame",
slots = c(timestamps = "POSIXt"))
df1 <- data.frame(x = 1:10, y = rnorm(10), z = sample(letters,10))
mydf1 <- new("myFrame", df1, timestamps = Sys.time())
```

"myFrame" objects inherit "data.frame" S3 methods; e.g., for `[`

```
mydf1[1:2, ] # a data frame object (with extra attributes)
```

A method explicitly for "myFrame" class

```
setMethod("[",
  signature(x = "myFrame"),
  function (x, i, j, ..., drop = TRUE)
  {
    S3Part(x) <- callNextMethod()
    x@timestamps <- c(Sys.time(), as.POSIXct(x@timestamps))
    x
  }
)
```

```
mydf1[1:2, ]
```

```
setClass("myDateTime", contains = "POSIXt")
```

```
now <- Sys.time() # class(now) is c("POSIXct", "POSIXt")
nowLt <- as.POSIXlt(now)# class(nowLt) is c("POSIXlt", "POSIXt")
mCt <- new("myDateTime", now)
mLt <- new("myDateTime", nowLt)
```

S3 methods for an S4 object will be selected using S4 inheritance

```
f3 <- function(x)UseMethod("f3") # an S3 generic to illustrate inheritance
```

```
f3.POSIXct <- function(x) "The POSIXct result"
f3.POSIXlt <- function(x) "The POSIXlt result"
f3.POSIXt <- function(x) "The POSIXt result"
```

```
stopifnot(identical(f3(mCt), f3.POSIXt(mCt)))
stopifnot(identical(f3(mLt), f3.POSIXt(mLt)))
```

An S4 object selects S3 methods according to its S4 "inheritance"

```
setClass("classA", contains = "numeric",
slots = c(realData = "numeric"))
```
Math.classA <- function(x) { (getFunction(.Generic))(x@realData) }
setMethod("Math", "classA", Math.classA)

x <- new("classA", log(1:10), realData = 1:10)
stopifnot(identical(abs(x), 1:10))

setClass("classB", contains = "classA")

y <- new("classB", x)
stopifnot(identical(abs(y), abs(x))) # (version 2.9.0 or earlier fails here)

## an S3 generic: just for demonstration purposes
f3 <- function(x, ...) UseMethod("f3")
f3.default <- function(x, ...) "Default f3"

## S3 method (only) for classA
f3.classA <- function(x, ...) "Class classA for f3"

## S3 and S4 method for numeric
f3.numeric <- function(x, ...) "Class numeric for f3"
setMethod("f3", "numeric", f3.numeric)

## The S3 method for classA and the closest inherited S3 method for classB
## are not found.

f3(x); f3(y) # both choose "numeric" method

## to obtain the natural inheritance, set identical S3 and S4 methods
setMethod("f3", "classA", f3.classA)

f3(x); f3(y) # now both choose "classA" method

## Need to define an S3 as well as S4 method to use on an S3 object
## or if called from a package without the S4 generic
MathFun <- function(x) { # a smarter "data.frame" method for Math group
  for (i in seq(length = ncol(x))[sapply(x, is.numeric)])
    x[, i] <- (getFunction(.Generic))(x[, i])
  x
}
setMethod("Math", "data.frame", MathFun)

## S4 method works for an S4 class containing data.frame,
## but not for data.frame objects (not S4 objects)
try(logIris <- log(iris)) # gets an error from the old method

## Define an S3 method with the same computation
Math.data.frame <- MathFun

logIris <- log(iris)
The S3 and S4 software in R are two generations implementing functional object-oriented programming. S3 is the original, simpler for initial programming but less general, less formal and less open to validation. The S4 formal methods and classes provide these features but require more programming.

In modern R, the two versions attempt to work together. This documentation outlines how to write methods for both systems by defining an S4 method for a function that dispatches S3 methods.

The systems can also be combined by using an S3 class with S4 method dispatch or in S4 class definitions. See `setOldClass`.

### S3 Method Dispatch

The R evaluator will ‘dispatch’ a method from a function call either when the body of the function calls the special primitive `UseMethod` or when the call is to one of the built-in primitives such as the math functions or the binary operators.

S3 method dispatch looks at the class of the first argument or the class of either argument in a call to one of the primitive binary operators. In pure S3 situations, ‘class’ in this context means the class attribute or the implied class for a basic data type such as "numeric". The first S3 method that matches a name in the class is called and the value of that call is the value of the original function call. For details, see `S3Methods`.

In modern R, a function `meth` in a package is registered as an S3 method for function `fun` and class `Class` by including in the package’s `NAMESPACE` file the directive

```
S3method(fun, Class, meth)
```

By default (and traditionally), the third argument is taken to be the function `fun.Class`; that is, the name of the generic function, followed by ".", followed by the name of the class.

As with S4 methods, a method that has been registered will be added to a table of methods for this function when the corresponding package is loaded into the session. Older versions of R, copying the mechanism in S, looked for the method in the current search list, but packages should now always register S3 methods rather than requiring the package to be attached.

### Methods for S4 Classes

Two possible mechanisms for implementing a method corresponding to an S4 class, there are two possibilities are to register it as an S3 method with the S4 class name or to define and set an S4 method, which will have the side effect of creating an S4 generic version of this function.

For most situations either works, but the recommended approach is to do both: register the S3 method and supply the identical function as the definition of the S4 method. This ensures that the proposed method will be dispatched for any applicable call to the function.
As an example, suppose an S4 class "uncased" is defined, extending "character" and intending to ignore upper- and lower-case. The base function `unique` dispatches S3 methods. To define the class and a method for this function:

```r
setClass("uncased", contains = "character")

unique.uncased <- function(x, incomparables = FALSE, ...)
  nextMethod(tolower(x))

setMethod("unique", "uncased", unique.uncased)
```

In addition, the `NAMESPACE` for the package should contain:

```r
S3method(unique, uncased)
exportMethods(unique)
```

The result is to define identical S3 and S4 methods and ensure that all calls to `unique` will dispatch that method when appropriate.

Details

The reasons for defining both S3 and S4 methods are as follows:

1. An S4 method alone will not be seen if the S3 generic function is called directly. This will be the case, for example, if some function calls `unique()` from a package that does not make that function an S4 generic.
   
   However, primitive functions and operators are exceptions: The internal C code will look for S4 methods if and only if the object is an S4 object. S4 method dispatch would be used to dispatch any binary operator calls where either of the operands was an S4 object, for example.

2. An S3 method alone will not be called if there is any eligible non-default S4 method.
   
   So if a package defined an S3 method for `unique` for an S4 class but another package defined an S4 method for a superclass of that class, the superclass method would be chosen, probably not what was intended.

S4 and S3 method selection are designed to follow compatible rules of inheritance, as far as possible. S3 classes can be used for any S4 method selection, provided that the S3 classes have been registered by a call to `setOldClass`, with that call specifying the correct S3 inheritance pattern. S4 classes can be used for any S3 method selection; when an S4 object is detected, S3 method selection uses the contents of `extends(class(x))` as the equivalent of the S3 inheritance (the inheritance is cached after the first call).

For the details of S4 and S3 dispatch see `Methods_Details` and `S3Methods`.

References

new

Generate an Object from a Class

Description

A call to new returns a newly allocated object from the class identified by the first argument. This call in turn calls the method for the generic function initialize corresponding to the specified class, passing the ... arguments to this method. In the default method for initialize(), named arguments provide values for the corresponding slots and unnamed arguments must be objects from superclasses of this class.

A call to a generating function for a class (see setClass) will pass its ... arguments to a corresponding call to new().

Usage

new(Class, ...)

initialize(.Object, ...)
Arguments

Class either the name of a class, a character string, (the usual case) or the object describing the class (e.g., the value returned by getClass). Note that the character string passed from a generating function includes the package name as an attribute, avoiding ambiguity if two packages have identically named classes.

... arguments to specify properties of the new object, to be passed to initialize().

.Object An object: see the “Initialize Methods” section.

Initialize Methods

The generic function initialize is not called directly. A call to new begins by copying the prototype object from the class definition, and then calls initialize() with this object as the first argument, followed by the ... arguments.

The interpretation of the ... arguments in a call to a generator function or to new() can be specialized to particular classes, by defining an appropriate method for "initialize".

In the default method, unnamed arguments in the ... are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Explicitly specified slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The initialize methods do not have to have ... as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, you should include ... as a formal argument, and your method should pass such arguments along via callNextMethod. This helps the definition of future subclasses of your class. If these have additional slots and your method does not have this argument, it will be difficult for these slots to be included in an initializing call.

See initialize-methods for a discussion of some classes with existing methods.

Methods for initialize can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the simpleInheritanceOnly argument to setGeneric and the discussion in setIs for the general concept.

Note that the basic vector classes, "numeric", etc. are implicitly defined, so one can use new for these classes. The ... arguments are interpreted as objects of this type and are concatenated into the resulting vector.

Classes_Details for details of class definitions, and setIsoldClass for the relation to S3 classes.

Examples

## using the definition of class "track" from \link(setClass)

```r
## a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)
```

```r
```
# a new object including an object from a superclass, plus a slot
t2 <- new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots. In this version, the slots must still be
### supplied by name.

setMethod("initialize", "track",
  function(.Object, ...) {
    .Object <- callNextMethod()
    if(length(.Object@x) != length(.Object@y))
      stop("specified x and y of different lengths")
    .Object
  })

### An alternative version that allows x and y to be supplied
### unnamed. A still more friendly version would make the default x
### a vector of the same length as y, and vice versa.

setMethod("initialize", "track",
  function(.Object, x = numeric(0), y = numeric(0), ...) {
    .Object <- callNextMethod(.Object, ...)
    if(length(x) != length(y))
      stop("specified x and y of different lengths")
    .Object@x <- x
    .Object@y <- y
    .Object
  })

---

**nonStructure-class**

A non-structure S4 Class for basic types

**Description**

S4 classes that are defined to extend one of the basic vector classes should contain the class
*structure* if they behave like structures; that is, if they should retain their class behavior under
math functions or operators, so long as their length is unchanged. On the other hand, if their class
depends on the values in the object, not just its structure, then they should lose that class under any
such transformations. In the latter case, they should be defined to contain *nonStructure*.

If neither of these strategies applies, the class likely needs some methods of its own for *Ops, Math,*
and/or other generic functions. What is not usually a good idea is to allow such computations to
drop down to the default, base code. This is inconsistent with most definitions of such classes.

**Methods**

Methods are defined for operators and math functions (groups *Ops, Math* and *Math2*. In all cases
the result is an ordinary vector of the appropriate type.

**References**

ObjectsWithPackage-class

A Vector of Object Names, with associated Package Names

Description

This class of objects is used to represent ordinary character string object names, extended with a
package slot naming the package associated with each object.

Objects from the Class

The function getGenerics returns an object of this class.

Slots

.Data: Object of class "character": the object names.
.package: Object of class "character": the package names.

Extends

Class "character", from data part.
Class "vector", by class "character".

See Also

Methods for general background.
promptClass  Generate a Shell for Documentation of a Formal Class

Description

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

Usage

```r
promptClass(clName, filename = NULL, type = "class",
            keywords = "classes", where = topenv(parent.frame()),
            generatorName = clName)
```

Arguments

- `clName`: a character string naming the class to be documented.
- `filename`: usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be NA (see below).
- `type`: the documentation type to be declared in the output file.
- `keywords`: the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.
- `where`: where to look for the definition of the class and of methods that use it.
- `generatorName`: the name for a generator function for this class; only required if a generator function was created and saved under a name different from the class name.

Details

The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using `getGenerics`). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.

As with other prompt-style functions, unless `filename` is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the meaning of the class. The output of `promptClass` can only contain information from the metadata about the formal definition and how it is used.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If a generator function is found assigned under the class name or the optional `generatorName`, skeleton documentation for that function is added to the file.

Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.
promptMethods

Generate a Shell for Documentation of Formal Methods

Description

Generates a shell of documentation for the methods of a generic function.

Usage

promptMethods(f, filename = NULL, methods)

Arguments

f a character string naming the generic function whose methods are to be documented.

filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, f followed by "-methods.Rd"). Can also be FALSE or NA (see below).

methods Optional methods list object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for f, these would be documented). If this argument is supplied, it is likely to be getMethods(f, where), with where some package containing methods for f.
Details

If filename is FALSE, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see prompt).

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = “\n”), where x is the list-style representation.

Otherwise, the documentation shell is written to the file specified by filename.

Value

If filename is FALSE, the text generated; if filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Objects With Fields Treated by Reference (OOP-style)

Description

The software described here allows packages to define reference classes that behave in the style of “OOP” languages such as Java and C++. This model for OOP differs from the functional model implemented by S4 (and S3) classes and methods, in which methods are defined for generic functions. Methods for reference classes are “encapsulated” in the class definition.

Computations with objects from reference classes invoke methods on them and extract or set their fields, using the ‘$’ operator in R. The field and method computations potentially modify the object. All computations referring to the objects see the modifications, in contrast to the usual functional programming model in R.

A call to setRefClass in the source code for a package defines the class and returns a generator object. Subsequent calls to the $methods() method of the generator will define methods for the class. As with functional classes, if the class is exported from the package, it will be available when the package is loaded.

Methods are R functions. In their usual implementation, they refer to fields and other methods of the class directly by name. See the section on “Writing Reference Methods”.

As with functional classes, reference classes can inherit from other reference classes via a contains= argument to setRefClass. Fields and methods will be inherited, except where the new class overrides method definitions. See the section on “Inheritance”.
**Usage**

```r
setRefClass(Class, fields = , contains = , methods =,
where =, inheritPackage =, ...)

getRefClass(Class, where =)
```

**Arguments**

- `Class` character string name for the class.
  In the call to `getRefClass()` this argument can also be any object from the relevant class.

- `fields` either a character vector of field names or a named list of the fields. The resulting fields will be accessed with reference semantics (see the section on “Reference Objects”). If the argument is a list, each element of the list should usually be the character string name of a class, in which case the object in the field must be from that class or a subclass. An alternative, but not generally recommended, is to supply an **accessor function**; see the section on “Implementation” for accessor functions and the related internal mechanism.
  Note that fields are distinct from slots. Reference classes should not define class-specific slots. See the note on slots in the “Implementation” section.

- `contains` optional vector of superclasses for this class. If a superclass is also a reference class, the fields and class-based methods will be inherited.

- `methods` a named list of function definitions that can be invoked on objects from this class. These can also be created by invoking the `$methods` method on the generator object returned. See the section on “Writing Reference Methods” for details.

- `where` for `setRefClass`, the environment in which to store the class definition. Should be omitted in calls from a package’s source code.
  For `getRefClass`, the environment from which to search for the definition. If the package is not loaded or you need to be specific, use `asNamespace` with the package name.

- `inheritPackage` Should objects from the new class inherit the package environment of a contained superclass? Default `FALSE`. See the Section “Inter-Package Superclasses and External Methods”.

- `...` other arguments to be passed to `setClass`.

**Value**

- `setRefClass()` returns a generator function suitable for creating objects from the class, invisibly.
  A call to this function takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the fields and unnamed arguments, if any, that are objects from one of the superclasses of this class (but only superclasses that are themselves reference classes have any effect).
  The generator function is similar to the S4 generator function returned by `setClass`. In addition to being a generator function, however, it is also a reference class generator object, with reference class methods for various utilities. See the section on reference class generator objects below.

- `getRefClass()` also returns the generator function for the class. Note that the package slot in the value is the correct package from the class definition, regardless of the `where` argument, which is used only to find the class if necessary.
Reference Classes

Reference Objects

Normal objects in $\mathcal{R}$ are passed as arguments in function calls consistently with functional programming semantics; that is, changes made to an object passed as an argument are local to the function call. The object that supplied the argument is unchanged.

The functional model (sometimes called pass-by-value, although this is inaccurate for $\mathcal{R}$) is suitable for many statistical computations and is implicit, for example, in the basic $\mathcal{R}$ software for fitting statistical models. In some other situations, one would like all the code dealing with an object to see the exact same content, so that changes made in any computation would be reflected everywhere. This is often suitable if the object has some “objective” reality, such as a window in a user interface.

In addition, commonly used languages, including Java, C++ and many others, support a version of classes and methods assuming reference semantics. The corresponding programming mechanism is to invoke a method on an object. In the $\mathcal{R}$ syntax we use "$\$" for this operation; one invokes a method, $m_1$ say, on an object $x$ by the expression $x\$m_1(...)$. Methods in this paradigm are associated with the object, or more precisely with the class of the object, as opposed to methods in a function-based class/method system, which are fundamentally associated with the function (in $\mathcal{R}$, for example, a generic function in an $\mathcal{R}$ session has a table of all its currently known methods). In this document “methods for a class” as opposed to “methods for a function” will make the distinction.

Objects in this paradigm usually have named fields on which the methods operate. In the $\mathcal{R}$ implementation, the fields are defined when the class is created. The field itself can optionally have a specified class, meaning that only objects from this class or one of its subclasses can be assigned to the field. By default, fields have class "ANY".

Fields are accessed by reference. In particular, invoking a method may modify the content of the fields.

Programming for such classes involves writing new methods for a particular class. In the $\mathcal{R}$ implementation, these methods are $\mathcal{R}$ functions, with zero or more formal arguments. For standard reference methods, the object itself is not an explicit argument to the method. Instead, fields and methods for the class can be referred to by name in the method definition. The implementation uses $\mathcal{R}$ environments to make fields and other methods available by name within the method. Specifically, the parent environment of the method is the object itself. See the section on “Writing Reference Methods”. This special use of environments is optional. If a method is defined with an initial formal argument $.self$, that will be passed in as the whole object, and the method follows the standard rules for any function in a package. See the section on “External Methods”.

The goal of the software described here is to provide a uniform programming style in $\mathcal{R}$ for software dealing with reference classes, whether implemented directly in $\mathcal{R}$ or through an interface to one of the OOP languages.

Writing Reference Methods

Reference methods are functions supplied as elements of a named list, either when invoking $\$methods()$ on a generator object $g$ or as the argument $methods$ in a call to setRefClass. The two mechanisms have the same effect, but the first makes the code more readable.

Methods are written as ordinary $\mathcal{R}$ functions but have some special features and restrictions in their usual form. In contrast to some other languages (e.g., Python), the object itself does not need to be an argument in the method definition. The body of the function can contain calls to any other reference method, including those inherited from other reference classes and may refer to methods and to fields in the object by name.

Alternatively, a method may be an external method. This is signalled by $.self$ being the first formal argument to the method. The body of the method then works like any ordinary function. The
Reference classes are called like other methods (without the .self argument, which is supplied internally and always refers to the object itself). Inside the method, fields and other methods are accessed in the form .self$x. External methods exist so that reference classes can inherit the package environment of superclasses in other packages; see the section on “External Methods”.

Fields may be modified in a method by using the non-local assignment operator, <<-, as in the $edit and $undo methods in the example below. Note that non-local assignment is required: a local assignment with the <- operator just creates a local object in the function call, as it would in any R function. When methods are installed, a heuristic check is made for local assignments to field names and a warning issued if any are detected.

Reference methods should be kept simple; if they need to do some specialized R computation, that computation should use a separate R function that is called from the reference method. Specifically, methods can not use special features of the enclosing environment mechanism, since the method’s environment is used to access fields and other methods. In particular, methods should not use non-exported entries in the package’s namespace, because the methods may be inherited by a reference class in another package.

Two method names are interpreted specially, initialize and finalize. If an initialize method is defined, it will be invoked when an object is generated from the class. See the discussion of method $new(...) in the section “Initialization Methods”.

If a finalize method is defined, a function will be registered to invoke it before the environment in the object is discarded by the garbage collector; finalizers are registered with atexit=TRUE, and so are also run at the end of R sessions. See the matrix viewer example for both initialize and finalize methods.

Reference methods can not themselves be generic functions; if you want additional function-based method dispatch, write a separate generic function and call that from the method.

Two special object names are available. The entire object can be referred to in a method by the reserved name .self. The object .refClassDef contains the definition of the class of the object. These are accessed as fields but are read-only, with one exception. In principal, the .self field can be modified in the $initialize method, because the object is still being created at this stage. This is not recommended, as it can invalidate the object with respect to its class.

The methods available include methods inherited from superclasses, as discussed in the section “Inheritance”.

Only methods actually used will be included in the environment corresponding to an individual object. To declare that a method requires a particular other method, the first method should include a call to $usingMethods() with the name of the other method as an argument. Declaring the methods this way is essential if the other method is used indirectly (e.g., via sapply() or do.call()). If it is called directly, code analysis will find it. Declaring the method is harmless in any case, however, and may aid readability of the source code.

Documentation for the methods can be obtained by the $help method for the generator object. Methods for classes are not documented in the Rd format used for R functions. Instead, the $help method prints the calling sequence of the method, followed by self-documentation from the method definition, in the style of Python. If the first element of the body of the method is a literal character string (possibly multi-line), that string is interpreted as documentation. See the method definitions in the example.

**Initialization Methods**

If the class has a method defined for $initialize(), this method will be called once the reference object has been created. You should write such a method for a class that needs to do some special initialization. In particular, a reference method is recommended rather than a method for the S4 generic function initialize(), because some special initialization is required for reference objects
before the initialization of fields. As with S4 classes, methods are written for $initialize() and
not for $new(), both for the previous reason and also because $new() is invoked on the generator
object and would be a method for that class.

The default method for $initialize() is equivalent to invoking the method $initFields(...).
Named arguments assign initial values to the corresponding fields. Unnamed arguments must be
objects from this class or a reference superclass of this class. Fields will be initialized to the contents
of the fields in such objects, but named arguments override the corresponding inherited fields. Note
that fields are simply assigned. If the field is itself a reference object, that object is not copied. The
new and previous object will share the reference. Also, a field assigned from an unnamed argument
counts as an assignment for locked fields. To override an inherited value for a locked field, the new
value must be one of the named arguments in the initializing call. A later assignment of the field
will result in an error.

Initialization methods need some care in design. The generator for a reference class will be called
with no arguments, for example when copying the object. To ensure that these calls do not fail, the
method must have defaults for all arguments or check for missing(). The method should include
... as an argument and pass this on via $callSuper() (or $initFields() if you know that your
superclasses have no initialization methods). This allows future class definitions that subclass this
class, with additional fields.

Inheritance

Reference classes inherit from other reference classes by using the standard R inheritance; that is,
by including the superclasses in the contains= argument when creating the new class. The names
of the reference superclasses are in slot refSuperClasses of the class definition. Reference classes
can inherit from ordinary S4 classes also, but this is usually a bad idea if it mixes reference fields
and non-reference slots. See the comments in the section on “Implementation”.

Class fields are inherited. A class definition can override a field of the same name in a superclass
only if the overriding class is a subclass of the class of the inherited field. This ensures that a valid
object in the field remains valid for the superclass as well.

Inherited methods are installed in the same way as directly specified methods. The code in a method
can refer to inherited methods in the same way as directly specified methods.

A method may override a method of the same name in a superclass. The overriding method can call
the superclass method by callSuper(...) as described below.

Methods Provided for all Objects

All reference classes inherit from the class "envRefClass". All reference objects can use the
following methods.

$callSuper(...) Calls the method inherited from a reference superclass. The call is meaningful
only from within another method, and will be resolved to call the inherited method of the
same name. The arguments to $callSuper are passed to the superclass version. See the
matrix viewer class in the example.

Note that the intended arguments for the superclass method must be supplied explicitly; there
is no convention for supplying the arguments automatically, in contrast to the similar mecha-
nism for functional methods.

$copy(shallow = FALSE) Creates a copy of the object. With reference classes, unlike ordinary
R objects, merely assigning the object with a different name does not create an independent
copy. If shallow is FALSE, any field that is itself a reference object will also be copied, and
similarly recursively for its fields. Otherwise, while reassigning a field to a new reference
object will have no side effect, modifying such a field will still be reflected in both copies
of the object. The argument has no effect on non-reference objects in fields. When there
are reference objects in some fields but it is asserted that they will not be modified, using
shallow = TRUE will save some memory and time.

$field(name, value) With one argument, returns the field of the object with character string
name. With two arguments, the corresponding field is assigned value. Assignment checks
that name specifies a valid field, but the single-argument version will attempt to get anything
of that name from the object’s environment.
The $field() method replaces the direct use of a field name, when the name of the field must
be calculated, or for looping over several fields.

$export(Class) Returns the result of coercing the object to Class (typically one of the super-
classes of the object’s class). Calling the method has no side effect on the object itself.

$getRefClass(); $getClass() These return respectively the generator object and the formal
class definition for the reference class of this object, efficiently.

$import(value, Class = class(value)) Import the object value into the current object, re-
placing the corresponding fields in the current object. Object value must come from one of
the superclasses of the current object’s class. If argument Class is supplied, value is first
coerced to that class.

$initFields(...) Initialize the fields of the object from the supplied arguments. This method is
usually only called from a class with a $initialize() method. It corresponds to the default
initialization for reference classes. If there are slots and non-reference superclasses, these may
be supplied in the ... argument as well.
Typically, a specialized $initialize() method carries out its own computations, then in-
vokes $initFields() to perform standard initialization, as shown in the matrixViewer class
in the example below.

$show() This method is called when the object is printed automatically, analogously to the show
function. A general method is defined for class "envRefClass". User-defined reference
classes will often define their own method: see the Example below.
Note two points in the example. As with any show() method, it is a good idea to print the class
effectively to allow for subclasses using the method. Second, to call the function show() from
the method, as opposed to the $show() method itself, refer to methods::show() explicitly.

$trace(what, ...), $untrace(what) Apply the tracing and debugging facilities of the trace
function to the reference method what.
All the arguments of the trace function can be supplied, except for signature, which is not
meaningful.
The reference method can be invoked on either an object or the generator for the class. See
the section on Debugging below for details.

$usingMethods(...) Reference methods used by this method are named as the arguments either
quoted or unquoted. In the code analysis phase of installing the the present method, the
declared methods will be included. It is essential to declare any methods used in a nonstandard
way (e.g., via an apply function). Methods called directly do not need to be declared, but it is
harmless to do so. $usingMethods() does nothing at run time.

Objects also inherit two reserved fields:

.self a reference to the entire object;
.refClassDef the class definition.

The defined fields should not override these, and in general it is unwise to define a field whose name
begins with ".", since the implementation may use such names for special purposes.
External Methods; Inter-Package Superclasses

The environment of a method in a reference class is the object itself, as an environment. This allows the method to refer directly to fields and other methods, without using the whole object and the "$" operator. The parent of that environment is the namespace of the package in which the reference class is defined. Computations in the method have access to all the objects in the package’s namespace, exported or not.

When defining a class that contains a reference superclass in another package, there is an ambiguity about which package namespace should have that role. The argument `inheritPackage` to `setRefClass()` controls whether the environment of new objects should inherit from an inherited class in another package or continue to inherit from the current package’s namespace.

If the superclass is “lean”, with few methods, or exists primarily to support a family of subclasses, then it may be better to continue to use the new package’s environment. On the other hand, if the superclass was originally written as a standalone, this choice may invalidate existing superclass methods. For the superclass methods to continue to work, they must use only exported functions in their package and the new package must import these.

Either way, some methods may need to be written that do not assume the standard model for reference class methods, but behave essentially as ordinary functions would in dealing with reference class objects.

The mechanism is to recognize external methods. An external method is written as a function in which the first argument, named `.self`, stands for the reference class object. This function is supplied as the definition for a reference class method. The method will be called, automatically, with the first argument being the current object and the other arguments, if any, passed along from the actual call.

Since an external method is an ordinary function in the source code for its package, it has access to all the objects in the namespace. Fields and methods in the reference class must be referred to in the form `.self$name`.

If for some reason you do not want to use `.self` as the first argument, a function `f()` can be converted explicitly as `externalRefMethod(f)`, which returns an object of class ”externalRefMethod” that can be supplied as a method for the class. The first argument will still correspond to the whole object.

External methods can be supplied for any reference class, but there is no obvious advantage unless they are needed. They are more work to write, harder to read and (slightly) slower to execute.

NOTE: If you are the author of a package whose reference classes are likely to be subclassed in other packages, you can avoid these questions entirely by writing methods that only use exported functions from your package, so that all the methods will work from another package that imports yours.

Reference Class Generators

The call to `setRefClass` defines the specified class and returns a “generator function” object for that class. This object has class ”refObjectGenerator”; it inherits from ”function” via ”classGeneratorFunction” and can be called to generate new objects from the reference class.

The returned object is also a reference class object, although not of the standard construction. It can be used to invoke reference methods and access fields in the usual way, but instead of being implemented directly as an environment it has a subsidiary generator object as a slot, a standard reference object (of class ”refGeneratorSlot”). Note that if one wanted to extend the reference class generator capability with a subclass, this should be done by subclassing ”refGeneratorSlot”, not ”refObjectGenerator”.
The fields are \texttt{def}, the class definition, and \texttt{className}, the character string name of the class. Methods generate objects from the class, to access help on reference methods, and to define new reference methods for the class. The currently available methods are:

\texttt{$new(\ldots)$} This method is equivalent to calling the generator function returned by \texttt{setRefClass}.

\texttt{$help(topic)$} Prints brief help on the topic. The topics recognized are reference method names, quoted or not. The information printed is the calling sequence for the method, plus self-documentation if any. Reference methods can have an initial character string or vector as the first element in the body of the function defining the method. If so, this string is taken as self-documentation for the method (see the section on “Writing Reference Methods” for details).

If no topic is given or if the topic is not a method name, the definition of the class is printed.

\texttt{$methods(\ldots)$} With no arguments, returns the names of the reference methods for this class. With one character string argument, returns the method of that name. Named arguments are method definitions, which will be installed in the class, as if they had been supplied in the methods argument to \texttt{setRefClass}(). Supplying methods in this way, rather than in the call to \texttt{setRefClass}(), is recommended for the sake of clearer source code. See the section on “Writing Reference Methods” for details.

All methods for a class should be defined in the source code that defines the class, typically as part of a package. In particular, methods can not be redefined in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. The new methods can refer to any currently defined method by name (including other methods supplied in this call to \texttt{$methods()$}). Note though that previously defined methods are not re-analyzed meaning that they will not call the new method (unless it redefines an existing method of the same name).

To remove a method, supply \texttt{NULL} as its new definition.

\texttt{$fields()$} Returns a list of the fields, each with its corresponding class. Fields for which an accessor function was supplied in the definition have class "\texttt{activeBindingFunction}".

\texttt{$lock(\ldots)$} The fields named in the arguments are locked; specifically, after the lock method is called, the field may be set once. Any further attempt to set it will generate an error. If called with no arguments, the method returns the names of the locked fields.

Fields that are defined by an explicit accessor function can not be locked (on the other hand, the accessor function can be defined to generate an error if called with an argument). All code to lock fields should normally be part of the definition of a class; that is, the read-only nature of the fields is meant to be part of the class definition, not a dynamic property added later. In particular, fields can not be locked in a class in an attached package with a namespace: The class method checks for a locked binding of the class definition. Locked fields can not be subsequently unlocked.

\texttt{$trace(what, \ldots, classMethod = FALSE)$} Establish a traced version of method \texttt{what} for objects generated from this class. The generator object tracing works like the \texttt{$trace()$} method for objects from the class, with two differences. Since it changes the method definition in the class object itself, tracing applies to all objects, not just the one on which the trace method is invoked.

Second, the optional argument \texttt{classMethod = TRUE} allows tracing on the methods of the generator object itself. By default, \texttt{what} is interpreted as the name of a method in the class for which this object is the generator.

\texttt{$accessors(\ldots)$} A number of systems using the OOP programming paradigm recommend or enforce getter and setter methods corresponding to each field, rather than direct access by name. If you like this style and want to extract a field named abc by \texttt{x$getAbc()} and assign it by \texttt{x=setAbc(value)}, the \texttt{$accessors$} method is a convenience function that creates such
getter and setter methods for the specified fields. Otherwise there is no reason to use this mechanism. In particular, it has nothing to do with the general ability to define fields by functions as described in the section on “Reference Objects”.

Implementation; Reference Classes as S4 Classes

Reference classes are implemented as S4 classes with a data part of type "environment". Fields correspond to named objects in the environment. A field associated with a function is implemented as an active binding. In particular, fields with a specified class are implemented as a special form of active binding to enforce valid assignment to the field.

As a related feature, the element in the fields= list supplied to setRefClass can be an accessor function, a function of one argument that returns the field if called with no argument or sets it to the value of the argument otherwise. Accessor functions are used internally and for inter-system interface applications, but not generally recommended as they blur the concept of fields as data within the object.

A field, say data, can be accessed generally by an expression of the form x$data for any object from the relevant class. In an internal method for this class, the field can be accessed by the name data. A field that is not locked can be set by an expression of the form x$data <- value. Inside an internal method, a field can be assigned by an expression of the form x <<- value. Note the non-local assignment operator. The standard R interpretation of this operator works to assign it in the environment of the object. If the field has an accessor function defined, getting and setting will call that function.

When a method is invoked on an object, the function defining the method is installed in the object’s environment, with the same environment as the environment of the function.

Reference classes can have validity methods in the same sense as any S4 class (see setValidity). Such methods are often a good idea; they will be called by calling validObject and a validity method, if one is defined, will be called when a reference object is created (from version 3.4 of R on). Just remember that these are S4 methods. The function will be called with the object as its argument. Fields and methods must be accessed using $.

Note: Slots. Because of the implementation, new reference classes can inherit from non-reference S4 classes as well as reference classes, and can include class-specific slots in the definition. This is usually a bad idea, if the slots from the non-reference class are thought of as alternatives to fields. Slots will always be treated functionally. Therefore, changes to the slots and the fields will behave inconsistently, mixing the functional and reference paradigms for properties of the same object, conceptually unclear and prone to errors. In addition, the initialization method for the class will have to sort out fields from slots, with a good chance of creating anomalous behavior for subclasses of this class.

Inheriting from a class union, however, is a reasonable strategy (with all members of the union likely to be reference classes).

Debugging

The standard R debugging and tracing facilities can be applied to reference methods. Reference methods can be passed to debug and its relatives from an object to debug further method invocations on that object; for example, debug(xx$edit).

Somewhat more flexible use is available for a reference method version of the trace function. A corresponding $trace() reference method is available for either an object or for the reference class generator (xx$trace() or mEdit$trace() in the example below). Using $trace() on an object sets up a tracing version for future invocations of the specified method for that object. Using $trace() on the generator for the class sets up a tracing version for all future objects from that
class (and sometimes for existing objects from the class if the method is not declared or previously invoked).

In either case, all the arguments to the standard `trace` function are available, except for `signature=` which is meaningless since reference methods can not be S4 generic functions. This includes the typical style `trace(what, browser)` for interactive debugging and `trace(what, edit = TRUE)` to edit the reference method interactively.

Examples

```r
## a simple editor for matrix objects. Method $edit() changes some
## range of values; method $undo() undoes the last edit.
mEdit <- setRefClass("mEdit",
  fields = list( data = "matrix",
                 edits = "list"))

## The basic edit, undo methods
mEdit$methods(
  edit = function(i, j, value) {
    ## the following string documents the edit method
    'Replaces the range [i, j] of the
    object by value.
    '
    backup <-
    list(i, j, data[i,j])
    data[i,j] <<- value
    edits <<- c(edits, list(backup))
    invisible(value)
  },
  undo = function() {
    'Undoes the last edit() operation
    and update the edits field accordingly.
    '
    prev <- edits
    if(length(prev)) prev <- prev[length(prev)]
    else stop("No more edits to undo")
    edit(prev[[1]], prev[[2]], prev[[3]])
    ## trim the edits list
    length(edits) <<- length(edits) - 2
    invisible(prev)
  })

## A method to automatically print objects
mEdit$methods(
  show = function() {
    'Method for automatically printing matrix editors'
    cat("Reference matrix editor object of class",
        classLabel(class(.self)), "\n")
    cat("Data: \n")
    methods::show(data)
    cat("Undo list is of length", length(edits), "\n")
  }
)
```

xMat <- matrix(1:12, 4, 3)
xx <- mEdit(data = xMat)
xx$edit(2, 2, 0)
xx
xx$undo()
mEdit$help("undo")
stopifnot(all.equal(xx$data, xMat))

utils::str(xx) # show fields and names of methods

## A method to save the object
mEdit$methods(
  save = function(file) {
    'Save the current object on the file
    in R external object format.'
    base::save(.self, file = file)
  }
)

tf <- tempfile()
xx$save(tf)

## Not run:
## Inheriting a reference class: a matrix viewer
mv <- setRefClass("matrixViewer",
  fields = c("viewerDevice", "viewerFile"),
  contains = "mEdit",
  methods = list( view = function() {

    dev.set(dev.prev())
    callSuper(...) ),
  finalize = function() {
    dev.off(viewerDevice)
  })

## debugging an object: call browser() in method $edit()
xx$trace(edit, browser)
## debugging all objects from class mEdit in method $undo()

mEdit$trace(undo, browser)

## End(Not run)

---

### removeMethod

**Remove a Method**

**Description**

Remove the method for a given function and signature. Obsolete for ordinary applications: Method definitions in a package should never need to remove methods and it’s very bad practice to remove methods that were defined in other packages.

**Usage**

```r
removeMethod(f, signature, where)
```

**Arguments**

- `f`, `signature`, `where`
  - As for `setMethod()`.

**Value**

`TRUE` if a method was found to be removed.

**References**

---

### representation

**Construct a Representation or a Prototype for a Class Definition**

**Description**

These are old utility functions to construct, respectively a list designed to represent the slots and superclasses and a list of prototype specifications. The `representation()` function is no longer useful, since the arguments `slots` and `contains` to `setClass` are now recommended.

The `prototype()` function may still be used for the corresponding argument, but a simple list of the same arguments works as well.

**Usage**

```r
representation(...)
prototype(...)
```
representation

Arguments

The call to representation takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to prototype, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The representation function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don’t have to exist when representation is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to prototype are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of representation is just the list of arguments, after these have been checked for validity.

The value of prototype is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does not use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

Examples

### representation for a new class with a directly define slot "smooth"
### which should be a "numeric" object, and extending class "track"
representation("track", smooth ="numeric")

### >>> This *is* old syntax -- use 'contains=*, slots=*' instead <<<
###                      ===========                    ===========

setClass("Character",representation("character"))
setClass("TypedCharacter",representation("Character",type="character"),
         prototype(character(0),type="plain"))
S3Part <- new("TypedCharacter", "foo", type = "character")

setClass("num1", representation(comment = "character"),
  contains = "numeric",
  prototype = prototype(pi, comment = "Start with pi"))

S3Part

S4 Classes that Contain S3 Classes

Description

A regular (S4) class may contain an S3 class, if that class has been registered (by calling `setOldClass`). The functions described here provide information about contained S3 classes. See the section 'Functions'.

In modern R, these functions are not usually needed to program with objects from the S4 class. Standard computations work as expected, including method selection for both S4 and S3. To coerce an object to its contained S3 class, use either of the expressions:

\[
\text{as(object, S3Class); as(object, "S3")}
\]

where S3Class evaluates to the name of the contained class. These return slightly different objects, which in rare cases may need to be distinguished. See the section “Contained S3 Objects”.

Usage

S3Part(object, strictS3 = FALSE, S3Class)

S3Class(object)

isXS3Class(classDef)

slotsFromS3(object)

## the replacement versions of the functions are not recommended
## Create a new object from the class or use the replacement version of as().

S3Part(object, strictS3 = FALSE, needClass = ) <- value

S3Class(object) <- value

Arguments

object

an object from some class that extends a registered S3 class, or a basic vector, matrix or array object type.

For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.
strictS3  If TRUE, the value returned by S3Part will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by setOldClass as a proxy for an S3 class, rather than the underlying S3 object.

S3Class  the character vector to be stored as the S3 class slot in the object. Usually, and by default, retains the slot from object, but an S3 superclass is allowed.

classDef  a class definition object, as returned by getClass. *The remaining arguments apply only to the replacement versions, which are not recommended.*

needClass  Require that the replacement value be this class or a subclass of it.

value  For S3Part<-, the replacement value for the S3 part of the object. For S3Class<-, the character vector that will be used as a proxy for class(x) in S3 method dispatch.

Functions

S3Part: Returns an object from the S3 class that appeared in the contains= argument to setClass.
If called with strictS3 = TRUE, S3Part() constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With strictS3 = FALSE the object returned is from the corresponding S4 class. For consistency and generality, S3Part() works also for classes that extend the basic vector, matrix and array classes.

A call to is equivalent coercing the object to class "S3" for the strict case, or to whatever the specific S3 class was, for the non-strict case. The as() calls are usually easier for readers to understand.

S3Class: Returns the character vector of S3 class(es) stored in the object, if the class has the corresponding .S3Class slot. Currently, the function defaults to class otherwise.

isXS3Class: Returns TRUE or FALSE according to whether the class defined by ClassDef extends S3 classes (specifically, whether it has the slot for holding the S3 class).

slotsFromS3: returns a list of the relevant slot classes, or an empty list for any other object.

The function slotsFromS3() is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when setOldClass is called with the S4Class argument. Usually, there is only one S3 slot, containing the S3 class, but the S4Class argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of setOldClass.

Contained S3 Objects

Registering an S3 class defines an S4 class. Objects from this class are essentially identical in content to an object from the S3 class, except for two differences. The value returned by class() will always be a single string for the S4 object, and isS4() will return TRUE or FALSE in the two cases. See the example below. It is barely possible that some S3 code will not work with the S4 object; if so, use as(x, "S3").

Objects from a class that extends an S3 class will have some basic type and possibly some attributes. For an S3 class that has an equivalent S4 definition (e.g., "data.frame"), an extending S4 class will have a data part and slots. For other S3 classes (e.g., "lm") an object from the extending S4 class will be some sort of basic type, nearly always a vector type (e.g., "list" for "lm"), but the data part will not have a formal definition.

Registering an S3 class by a call to setOldClass creates a class of the same name with a slot ".S3Class" to hold the corresponding S3 vector of class strings. New S4 classes that extend such
classes also have the same slot, set to the S3 class of the contained S3 object, which may be an (S3) subclass of the registered class. For example, an S4 class might contain the S3 class "lm", but an object from the class might contain an object from class "mlm", as in the "xlm" example below.

R is somewhat arbitrary about what it treats as an S3 class: "ts" is, but "matrix" and "array" are not. For classes that extend those, assuming they contain an S3 class is incorrect and will cause some confusion—not usually disastrous, but the better strategy is to stick to the explicit "class". Thus `as(x, "matrix")` rather than `as(x, "S3")` or `S3Part(x)`.

### S3 and S4 Objects: Conversion Mechanisms

Objects in R have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by `isS4` and can be set on or off by `asS4`. The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions `as(object, "S3")` and `as(object, "S4")` return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression `as(object, "S3")` can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by `class(object)`. If the registered class has known attribute/slots, these will also be provided.

Another use of `as(object, "S3")` is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression `as(object, "S4")` will use the attributes in the object to create an object from the S4 definition of `class(object)`. This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking `new` with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

### Examples

```r
## an "mlm" object, regressing two variables on two others
sepal <- as.matrix(datasets::iris[,c("Sepal.Width", "Sepal.Length")])
fit <- lm(sepal ~ Petal.Length + Petal.Width + Species, data = datasets::iris)
class(fit) # S3 class: "mlm", "lm"

## a class that contains "mlm"
myReg <- setClass("myReg", slots = c(title = "character"), contains = "mlm")
fit2 <- myReg(fit, title = "Sepal Regression for iris data")

fit2 # shows the inherited "mlm" object and the title
```
identical(S3Part(fit2), as(fit2, "mlm"))

class(as(fit2, "mlm")) # the S4 class, "mlm"

class(as(fit2, "S3")) # the S3 class, c("mlm", "lm")

## An object may contain an S3 class from a subclass of that declared:
xlm <- setClass("xlm", slots = c(eps = "numeric"), contains = "lm")

xfit <- xlm(fit, eps = .Machine$double.eps)

xfit@.S3Class # c("mlm", "lm")

---

S4groupGeneric S4 Group Generic Functions

Description

Methods can be defined for group generic functions. Each group generic function has a number of member generic functions associated with it.

Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the methods package, but the mechanism is available to any programmer, by calling setGroupGeneric (provided package methods is attached).

Usage

## S4 group generics:
Arith(e1, e2)
Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(z)

Arguments

x, z, e1, e2 objects.
digits number of digits to be used in round or signif.
... further arguments passed to or from methods.
na.rm logical: should missing values be removed?
Details

Methods can be defined for the group generic functions by calls to setMethod in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see Methods_Details.

There are also S3 groups Math, Ops, Summary and Complex, see ?S3groupGeneric, with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling getGroupMembers. For the group generic functions currently defined in this package the members are as follows:

Arith "+", "-", "*", "^", "%%", "%/%", "/"

Compare "==", "\n", "<\n", "!=", "<=\n", ">="

Logic "&", "|".

Ops "Arith", "Compare", "Logic"

Math2 "round", "signif"

Summary "max", "min", "range", "prod", "sum", "any", "all"

Complex "Arg", "Conj", "Im", "Mod", "Re"

Note that Ops merely consists of three sub groups.

All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives. However, you can still define formal methods for them, both individually and via the group generics. It all works more or less as you might expect, admittedly via a bit of trickery in the background. See Methods_Details for details.

Note that two members of the Math group, log and trunc, have ... as an extra formal argument. Since methods for Math will have only one formal argument, you must set a specific method for these functions in order to call them with the extra argument(s).

For further details about group generic functions see section 10.5 of the second reference.

See Also

The function callGeneric is nearly always relevant when writing a method for a group generic. See the examples below and in section 10.5 of Software for Data Analysis.

See S3groupGeneric for S3 group generics.
Examples

```r
setClass("testComplex", slots = c(zz = "complex"))
## method for whole group "Complex"
getMethod("Complex", "testComplex", 
    function(z) c("groupMethod", callGeneric(z@zz)))
## exception for Arg():
getMethod("Arg", "testComplex", 
    function(z) c("ArgMethod", Arg(z@zz)))

z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
```

SClassExtension-class  
Class to Represent Inheritance (Extension) Relations

Description

An object from this class represents a single ‘is’ relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

Objects from the Class

Objects from this class are generated by `setIs`, from direct calls and from the contains= information in a call to `setClass`, and from class unions created by `setClassUnion`. In the last case, the information is stored in defining the subclasses of the union class (allowing unions to contain sealed classes).

Slots

- `subClass`, `superClass`: The classes being extended: corresponding to the from, and to arguments to `setIs`.
- `package`: The package to which that class belongs.
- `coerce`: A function to carry out the as() computation implied by the relation. Note that these functions should not be used directly. They only deal with the strict=TRUE calls to the as function, with the full method constructed from this mechanically.
- `test`: The function that would test whether the relation holds. Except for explicitly specified test arguments to `setIs`, this function is trivial.
- `replace`: The method used to implement as(x, Class) <- value.
- `simple`: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.
- `by`: If this relation has been constructed transitively, the first intermediate class from the subclass.
- `dataPart`: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).
- `distance`: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.
selectSuperClasses

Super Classes (of Specific Kinds) of a Class

Description
Return superclasses of ClassDef, possibly only non-virtual or direct or simple ones. These functions are designed to be fast, and consequently only work with the contains slot of the corresponding class definitions.

Usage
```r
selectSuperClasses(Class, dropVirtual = FALSE, namesOnly = TRUE,
                    directOnly = TRUE, simpleOnly = directOnly,
                    where = topenv(parent.frame()))
.
.selectSuperClasses(ext, dropVirtual = FALSE, namesOnly = TRUE,
                    directOnly = TRUE, simpleOnly = directOnly)
```

Arguments
- **Class**: name of the class or (more efficiently) the class definition object (see `getClass`).
- **dropVirtual**: logical indicating if only non-virtual superclasses should be returned.
- **namesOnly**: logical indicating if only a vector names instead of a named list class-extensions should be returned.
- **directOnly**: logical indicating if only a direct super classes should be returned.
- **simpleOnly**: logical indicating if only simple class extensions should be returned.
- **where**: (only used when Class is not a class definition) environment where the class definition of Class is found.
- **ext**: for `.selectSuperClasses()` only, a list of class extensions, typically `getClassDef(..)@contains`.

Value
- a character vector (if namesOnly is true, as per default) or a list of class extensions (as the contains slot in the result of `getClass`).

Note
The typical user level function is `selectSuperClasses()` which calls `.selectSuperClasses()`, i.e., the latter should only be used for efficiency reasons by experienced useRs.
See Also

is, getClass; further, the more technical class classRepresentation documentation.

Examples

setClass("Root")
setClass("Base", contains = "Root", slots = c(length = "integer"))
setClass("A", contains = "Base", slots = c(x = "numeric"))
setClass("B", contains = "Base", slots = c(y = "character"))
setClass("C", contains = c("A", "B"))

extends("C")  #--> "C"  "A"  "B"  "Base"  "Root"
selectSuperClasses("C") # "A"  "B"
selectSuperClasses("C", direct=FALSE) # "A"  "B"  "Base"  "Root"
selectSuperClasses("C", dropVirt = TRUE, direct=FALSE)# ditto w/o "Root"

setAs Methods for Coercing an Object to a Class

Description

A call to setAs defines a method for coercing an object of class `from` to class `to`. The methods will then be used by calls to `as` for objects with class `from`, including calls that replace part of the object.

Methods for this purpose work indirectly, by defining methods for function `coerce`. The `coerce` function is not to be called directly, and method selection uses class inheritance only on the first argument.

Usage

```r
setAs(from, to, def, replace, where = topenv(parent.frame()))
```

Arguments

- `from, to` The classes between which the coerce methods `def` and `replace` perform coercion.
- `def` function of one argument. It will get an object from class `from` and had better return an object of class `to`. The convention is that the name of the argument is `from`; if another argument name is used, setAs will attempt to substitute `from`.
- `replace` if supplied, the function to use as a replacement method, when `as` is used on the left of an assignment. Should be a function of two arguments, `from`, `value`, although setAs will attempt to substitute if the arguments differ. *The remaining argument will not be used in standard applications.*
- `where` the position or environment in which to store the resulting methods. Do not use this argument when defining a method in a package. Only the default, the namespace of the package, should be used in normal situations.
Inheritance and Coercion

Objects from one class can turn into objects from another class either automatically or by an explicit call to the as function. Automatic conversion is special, and comes from the designer of one class of objects asserting that this class extends another class. The most common case is that one or more class names are supplied in the contains= argument to setClass, in which case the new class extends each of the earlier classes (in the usual terminology, the earlier classes are superclasses of the new class and it is a subclass of each of them).

This form of inheritance is called simple inheritance in R. See setClass for details. Inheritance can also be defined explicitly by a call to setIs. The two versions have slightly different implications for coerce methods. Simple inheritance implies that inherited slots behave identically in the subclass and the superclass. Whenever two classes are related by simple inheritance, corresponding coerce methods are defined for both direct and replacement use of as. In the case of simple inheritance, these methods do the obvious computation: they extract or replace the slots in the object that correspond to those in the superclass definition.

The implicitly defined coerce methods may be overridden by a call to setAs; note, however, that the implicit methods are defined for each subclass-superclass pair, so that you must override each of these explicitly, not rely on inheritance.

When inheritance is defined by a call to setIs, the coerce methods are provided explicitly, not generated automatically. Inheritance will apply (to the from argument, as described in the section below). You could also supply methods via setAs for non-inherited relationships, and now these also can be inherited.

For further on the distinction between simple and explicit inheritance, see setIs.

How Functions 'as' and 'setAs' Work

The function as turns object into an object of class Class. In doing so, it applies a “coerce method”, using S4 classes and methods, but in a somewhat special way. Coerce methods are methods for the function coerce or, in the replacement case the function `coerce<-. These functions have two arguments in method signatures, from and to, corresponding to the class of the object and the desired coerce class. These functions must not be called directly, but are used to store tables of methods for the use of as, directly and for replacements. In this section we will describe the direct case, but except where noted the replacement case works the same way, using `coerce<-' and the replace argument to setAs, rather than coerce and the def argument.

Assuming the object is not already of the desired class, as first looks for a method in the table of methods for the function coerce for the signature c(from = class(object), to = Class), in the same way method selection would do its initial lookup. To be precise, this means the table of both direct and inherited methods, but inheritance is used specially in this case (see below).

If no method is found, as looks for one. First, if either Class or class(object) is a superclass of the other, the class definition will contain the information needed to construct a coerce method. In the usual case that the subclass contains the superclass (i.e., has all its slots), the method is constructed either by extracting or replacing the inherited slots. Non-simple extensions (the result of a call to setIs) will usually contain explicit methods, though possibly not for replacement.

If no subclass/superclass relationship provides a method, as looks for an inherited method, but applying, inheritance for the argument from only, not for the argument to (if you think about it, you’ll probably agree that you wouldn’t want the result to be from some class other than the Class specified). Thus, selectMethod("coerce", sig, useInherited= c(from=TRUE, to= FALSE)) replicates the method selection used by as().

In nearly all cases the method found in this way will be cached in the table of coerce methods (the exception being subclass relationships with a test, which are legal but discouraged). So the detailed calculations should be done only on the first occurrence of a coerce from class(object) to Class.
Note that coerce is not a standard generic function. It is not intended to be called directly. To prevent accidentally caching an invalid inherited method, calls are routed to an equivalent call to as, and a warning is issued. Also, calls to `selectMethod` for this function may not represent the method that as will choose. You can only trust the result if the corresponding call to as has occurred previously in this session.

With this explanation as background, the function `setAs` does a fairly obvious computation: It constructs and sets a method for the function coerce with signature `c(from, to)`, using the `def` argument to define the body of the method. The function supplied as `def` can have one argument (interpreted as an object to be coerced) or two arguments (the `from` object and the `to` class). Either way, `setAs` constructs a function of two arguments, with the second defaulting to the name of the `to` class. The method will be called from `as` with the object as the `from` argument and no `to` argument, with the default for this argument being the name of the intended `to` class, so the method can use this information in messages.

The direct version of the `as` function also has a `strict=` argument that defaults to `TRUE`. Calls during the evaluation of methods for other functions will set this argument to `FALSE`. The distinction is relevant when the object being coerced is from a simple subclass of the `to` class; if `strict=FALSE` in this case, nothing need be done. For most user-written coerce methods, when the two classes have no subclass/superclass, the `strict=` argument is irrelevant.

The `replace` argument to `setAs` provides a method for `\texttt{\textasciitilde suppressRendering~\textasciitilde coerce~\textasciitilde suppressRendering~\textasciitilde}`. As with all replacement methods, the last argument of the method must have the name `value` for the object on the right of the assignment. As with the coerce method, the first two arguments are `from`, `to`; there is no `strict= option for the replace case.

The function `coerce` exists as a repository for such methods, to be selected as described above by the `as` function. Actually dispatching the methods using `standardGeneric` could produce incorrect inherited methods, by using inheritance on the `to` argument; as mentioned, this is not the logic used for as. To prevent selecting and caching invalid methods, calls to `coerce` are currently mapped into calls to `as`, with a warning message.

### Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, `as(x, "numeric")` uses the existing `as.numeric` function. These built-in methods can be listed by `showMethods("coerce").`

### References

### See Also

If you think of using `try(as(x, cl))`, consider `canCoerce(x, cl)` instead.

### Examples

```r
## using the definition of class "track" from \link{setClass}

setAs("track", "numeric", function(from) from@y)

t1 <- new("track", x=1:20, y=(1:20)^2)
as(t1, "numeric")
```
## The next example shows:
## 1. A virtual class to define setAs for several classes at once.
## 2. as() using inherited information

```r
setClass("ca", slots = c(a = "character", id = "numeric"))
setClass("cb", slots = c(b = "character", id = "numeric"))
setClass("id")
setIs("ca", "id")
setIs("cb", "id")

setAs("id", "numeric", function(from) from@id)

CA <- new("ca", a = "A", id = 1)
CB <- new("cb", b = "B", id = 2)

setAs("cb", "ca", function(from, to) new(to, a=from@b, id = from@id))

as(CB, "numeric")
```

---

### setClass

**Create a Class Definition**

Create a class definition and return a generator function to create objects from the class. Typical usage will be of the style:

```r
myClass <- setClass("myClass", slots = ...., contains = ....)
```

where the first argument is the name of the new class and, if supplied, the arguments `slots=` and `contains=` specify the slots in the new class and existing classes from which the new class should inherit. Calls to `setClass()` are normally found in the source of a package; when the package is loaded the class will be defined in the package’s namespace. Assigning the generator function with the name of the class is convenient for users, but not a requirement.

### Usage

```r
setClass(Class, representation, prototype, contains=character(),
validity, access, where, version, sealed, package,
S3methods = FALSE, slots)
```

### Arguments

- **Class** character string name for the class.
- **slots** The names and classes for the slots in the new class. This argument must be supplied by name, `slots=`, in the call, for back compatibility with other arguments no longer recommended.
The argument must be vector with a names attribute, the names being those of the slots in the new class. Each element of the vector specifies an existing class; the corresponding slot must be from this class or a subclass of it. Usually, this is a character vector naming the classes. It’s also legal for the elements of the vector to be class representation objects, as returned by `getClass`.

As a limiting case, the argument may be an unnamed character vector; the elements are taken as slot names and all slots have the unrestricted class "ANY".

`contains` A vector specifying existing classes from which this class should inherit. The new class will have all the slots of the superclasses, with the same requirements on the classes of these slots. This argument must be supplied by name, `contains=` in the call, for back compatibility with other arguments no longer recommended.

See the section ‘Virtual Classes’ for the special superclass "VIRTUAL".

`prototype, where, validity, sealed, package` These arguments are currently allowed, but either they are unlikely to be useful or there are modern alternatives that are preferred.

`prototype`: supplies an object with the default data for the slots in this class. A more flexible approach is to write a method for `initialize()`.

`where`: supplies an environment in which to store the definition. Should not be used: For calls to `setClass()` appearing in the source code for a package the definition will be stored in the namespace of the package.

`validity`: supplied a validity-checking method for objects from this class. For clearer code, use a separate call to `setValidity()`.

`sealed`: if TRUE, the class definition will be sealed, so that another call to `setClass` will fail on this class name. But the definition is automatically sealed after the namespace is loaded, so explicit sealing is not needed.

`package`: supplies an optional package name for the class, but the class attribute should be the package in which the class definition is assigned, as it is by default.

`representation, access, version, S3methods` All these arguments are deprecated from version 3.0.0 of R and should be avoided.

`representation` is an argument inherited from S that included both slots and `contains`, but the use of the latter two arguments is clearer and recommended.

`access` and `version` are included for historical compatibility with S-Plus, but ignored.

`S3methods` is a flag indicating that old-style methods will be written involving this class; ignored now.

### Value

A generator function suitable for creating objects from the class is returned, invisibly. A call to this function generates a call to `new` for the class. The call takes any number of arguments, which will be passed on to the initialize method. If no initialize method is defined for the class or one of its superclasses, the default method expects named arguments with the name of one of the slots and unnamed arguments that are objects from one of the contained classes.

Typically the generator function is assigned the name of the class, for programming clarity. This is not a requirement and objects from the class can also be generated directly from `new`. The advantages of the generator function are a slightly simpler and clearer call, and that the call will contain the package name of the class (eliminating any ambiguity if two classes from different packages have the same name).
If the class is virtual, an attempt to generate an object from either the generator or \texttt{new()} will result in an error.

**Basic Use: Slots and Inheritance**

The two essential arguments other than the class name are \texttt{slots} and \texttt{contains}, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.

The name of the class determines which methods apply directly to objects from this class. The superclass information specifies which methods apply indirectly, through inheritance. See \texttt{Methods_Details} for inheritance in method selection.

The slots in a class definition will be the union of all the slots specified directly by \texttt{slots} and all the slots in all the contained classes. There can only be one slot with a given name. A class may override the definition of a slot with a given name, but only if the newly specified class is a subclass of the inherited one. For example, if the contained class had a slot \texttt{a} with class "ANY", then a subclass could specify a with class "numeric", but if the original specification for the slot was class "character", the new call to \texttt{setClass} would generate an error.

Slot names "class" and "Class" are not allowed. There are other slot names with a special meaning; these names start with the "." character. To be safe, you should define all of your own slots with names starting with an alphabetic character.

Some inherited classes will be treated specially—object types, S3 classes and a few special cases—whether inherited directly or indirectly. See the next three sections.

**Virtual Classes**

Classes exist for which no actual objects can be created, the virtual classes.

The most common and useful form of virtual class is the class union, a virtual class that is defined in a call to \texttt{setClassUnion()} rather than a call to \texttt{setClass()}. This call lists the members of the union—subclasses that extend the new class. Methods that are written with the class union in the signature are eligible for use with objects from any of the member classes. Class unions can include as members classes whose definition is otherwise sealed, including basic R data types.

Calls to \texttt{setClass()} will also create a virtual class, either when only the \texttt{Class} argument is supplied (no slots or superclasses) or when the \texttt{contains=} argument includes the special class name "VIRTUAL".

In the latter case, a virtual class may include slots to provide some common behavior without fully defining the object—see the class \texttt{traceable} for an example. Note that "VIRTUAL" does not carry over to subclasses; a class that contains a virtual class is not itself automatically virtual.

**Inheriting from Object Types**

In addition to containing other S4 classes, a class definition can contain either an S3 class (see the next section) or a built-in R pseudo-class—one of the R object types or one of the special R pseudo-classes "matrix" and "array". A class can contain at most one of the object types, directly or indirectly. When it does, that contained class determines the "data part" of the class. This appears as a pseudo-slot, "\_Data" and can be treated as a slot but actually determines the type of objects from this slot.

Objects from the new class try to inherit the built-in behavior of the contained type. In the case of normal R data types, including vectors, functions and expressions, the implementation is relatively straightforward. For any object \(x\) from the class, \texttt{typeof(x)} will be the contained basic type; and a special pseudo-slot, \_.Data, will be shown with the corresponding class. See the "numWithId" example below.
Classes may also inherit from "vector", "matrix" or "array". The data part of these objects can be any vector data type.

For an object from any class that does not contain one of these types or classes, typeof(x) will be "S4".

Some R data types do not behave normally, in the sense that they are non-local references or other objects that are not duplicated. Examples include those corresponding to classes "environment", "externalptr", and "name". These can not be the types for objects with user-defined classes (either S4 or S3) because setting an attribute overwrites the object in all contexts. It is possible to define a class that inherits from such types, through an indirect mechanism that stores the inherited object in a reserved slot, ".xData". See the example for class "stampedEnv" below. An object from such a class does not have a ".Data" pseudo-slot.

For most computations, these classes behave transparently as if they inherited directly from the anomalous type. S3 method dispatch and the relevant as.type() functions should behave correctly, but code that uses the type of the object directly will not. For example, as.environment(e1) would work as expected with the "stampedEnv" class, but typeof(e1) is "S4".

Inheriting from S3 Classes

Old-style S3 classes have no formal definition. Objects are “from” the class when their class attribute contains the character string considered to be the class name.

Using such classes with formal classes and methods is necessarily a risky business, since there are no guarantees about the content of the objects or about consistency of inherited methods. Given that, it is still possible to define a class that inherits from an S3 class, providing that class has been registered as an old class (see setOldClass).

Broadly speaking, both S3 and S4 method dispatch try to behave sensibly with respect to inheritance in either system. Given an S4 object, S3 method dispatch and the inherits function should use the S4 inheritance information. Given an S3 object, an S4 generic function will dispatch S4 methods using the S3 inheritance, provided that inheritance has been declared via setOldClass. For details, see setOldClass and Section 10.8 of the reference.

Classes and Packages

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the classRepresentation object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.

When a class name is supplied for a slot or a superclass in a call to setClass, a corresponding class definition will be found, looking from the namespace of the current package, assuming the call in question appears directly in the source for the package, as it should to avoid ambiguity. The class definition must be already defined in this package, in the imports directives of the package’s DESCRIPTION and NAMESPACE files or in the basic classes defined by the methods package. (The ‘methods’ package must be included in the imports directives for any package that uses S4 methods and classes, to satisfy the "CMD check" utility.)

If a package imports two classes of the same name from separate packages, the packageSlot of the name argument needs to be set to the package name of the particular class. This should be a rare occurrence.

Examples

```r
## A simple class with two slots
track <- setClass("track", slots = c(x="numeric", y="numeric"))
## an object from the class
t1 <- track(x = 1:10, y = 1:10 + rnorm(10))

## A class extending the previous, adding one more slot
trackCurve <- setClass("trackCurve", 
  slots = c(smooth = "numeric"), contains = "track")
## an object containing a superclass object
t1s <- trackCurve(t1, smooth = 1:10)

## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve", 
  slots = c(x="numeric", y="matrix", smooth="matrix"),
  prototype = list(x=numeric(), y=matrix(0,0,0),
                    smooth= matrix(0,0,0)))

## A class that extends the built-in data type "numeric"
numWithId <- setClass("numWithId", c(id = "character"), contains = "numeric")
numWithId(1:3, id = "An Example")

## inherit from reference object of type "environment"
stampedEnv <- setClass("stampedEnv", contains = "environment", 
  slots = c(update = "POSIXct"))
setMethod("[[<-", c("stampedEnv", "character", "missing"), function(x, i, j, ..., value) {
  ev <- as(x, "environment")
  ev[[i]] <- value #update the object in the environment
  x@update <- Sys.time() # and the update time
})

e1 <- stampedEnv(update = Sys.time())

e1["noise"] <- rnorm(10)
```

---

**setClassUnion**

**Classes Defined as the Union of Other Classes**
**setClassUnion**

**Description**

A class may be defined as the union of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

**Usage**

```r
setClassUnion(name, members, where)
isClassUnion(Class)
```

**Arguments**

- **name**
  the name for the new union class.

- **members**
  the names of the classes that should be members of this union.

- **where**
  where to save the new class definition. In calls from a package’s source code, should be omitted to save the definition in the package’s namespace.

- **Class**
  the name or definition of a class.

**Details**

The classes in `members` must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

Class unions are the only way to create a new superclass of a class whose definition is sealed. The namespace of all packages is sealed when the package is loaded, protecting the class and other definitions from being overwritten from another class or from the global environment. A call to `setIs` that tried to define a new superclass for class "numeric", for example, would cause an error.

Class unions are the exception; the class union "maybeNumber" in the examples defines itself as a new superclass of "numeric". Technically, it does not alter the metadata object in the other package’s namespace and, of course, the effect of the class union depends on loading the package it belongs to. But, basically, class unions are sufficiently useful to justify the exemption.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class `classRepresentation`.

**References**

**Examples**

```r
## a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

## use the union as the data part of another class
setClass("withId", contains = "maybeNumber", slots = c(id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%%1 < .01, id = "Perfect squares")

## add class "complex" to the union "maybeNumber"
setIs("complex", "maybeNumber")
```
w3 <- new("withId", complex(real = 1:10, imaginary = sqrt(1:10)))

## a class union containing the existing class union "OptionalFunction"
setClassUnion("maybeCode",
  c("expression", "language", "OptionalFunction"))

is(quote(sqrt(1:10)), "maybeCode") ## TRUE

---

setGeneric

Create a Generic Version of a Function

Description

Create a generic version of the named function so that methods may be defined for it. A call to setMethod will call setGeneric automatically if applied to a non-generic function.

An explicit call to setGeneric is usually not required, but doesn’t hurt and makes explicit that methods are being defined for a non-generic function.

Standard calls will be of the form:

setGeneric(name)

where name specifies an existing function, possibly in another package. An alternative when creating a new generic function in this package is:

setGeneric(name, def)

where the function definition def specifies the formal arguments and becomes the default method.

Usage

setGeneric(name, def= , group=list(), valueClass=character(),
  where= , package= , signature= , useAsDefault= ,
  genericFunction= , simpleInheritanceOnly = )

Arguments

name

The character string name of the generic function.

def

An optional function object, defining the non-generic version, to become the default method. This is equivalent in effect to assigning def as the function and then using the one-argument call to setGeneric.

The following arguments are specialized, optionally used when creating a new generic function with non-standard features. They should not be used when the non-generic is in another package.

group

The name of the group generic function to which this function belongs. See Methods_Details for details of group generic functions in method selection and S4groupGeneric for existing groups.

valueClass

A character vector specifying one or more class names. The value returned by the generic function must have (or extend) this class, or one of the classes; otherwise, an error is generated.
signature
The vector of names from among the formal arguments to the function, that will
be allowed in the signature of methods for this function, in calls to `setMethod`
By default and usually, this will be all formal arguments except ...
A non-standard signature for the generic function may be used to exclude argu-
ments that take advantage of lazy evaluation; in particular, if the argument may
not be evaluated then it cannot be part of the signature.
While ... cannot be used as part of a general signature, it is possible to have this
as the only element of the signature. Methods will then be selected if their sig-
nature matches all the ... arguments. See the documentation for topic dotsMeth-
ods for details. It is not possible to mix ... and other arguments in the signature.
It's usually a mistake to omit arguments from the signature in the belief that this
improves efficiency. For method selection, the arguments that are used in the
signatures for the methods are what counts, and then only seriously on the first
call to the function with that combination of classes.
simpleInheritanceOnly
Supply this argument as TRUE to require that methods selected be inherited
through simple inheritance only: that is, from superclasses specified in the
contains= argument to `setClass`, or by simple inheritance to a class union
or other virtual class. Generic functions should require simple inheritance if
they need to be assured that they get the complete original object, not one that
has been transformed. Examples of functions requiring simple inheritance are
initialize, because by definition it must return an object from the same class
as its argument, and show, because it claims to give a full description of the
object provided as its argument.
useAsDefault
Override the usual default method mechanism. Only relevant when defining a
nonstandard generic function. See the section ‘Specialized Local Generics’.
The remaining arguments are obsolete for normal applications.
package
The name of the package with which this function is associated. Should be
determined automatically from the non-generic version.
where
Where to store the resulting objects as side effects. The default, to store in the
package’s namespace, is the only safe choice.
genericFunction
Obsolete.

Value
The `setGeneric` function exists for its side effect: saving the generic function to allow methods to
be specified later. It returns name.

Basic Use
The `setGeneric` function is called to initialize a generic function as preparation for defining some
methods for that function.
The simplest and most common situation is that name specifies an existing function, usually in
another package. You now want to define methods for this function. In this case you should supply
only name, for example:

```r
setGeneric("colSums")
```
There must be an existing function of this name (in this case in package "base"). The non-generic
function can be in the same package as the call, typically the case when you are creating a new
function plus methods for it. When the function is in another package, it must be available by name,
for example through an `importFrom()` directive in this package’s NAMESPACE file. Not required for functions in "base", which are implicitly imported.

A generic version of the function will be created in the current package. The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function ("base" in the example).

Two special types of non-generic should be noted. Functions that dispatch S3 methods by calling `UseMethod` are ordinary functions, not objects from the "genericFunction" class. They are made generic like any other function, but some special considerations apply to ensure that S4 and S3 method dispatch is consistent (see Methods_for_S3).

Primitive functions are handled in C code and don’t exist as normal functions. A call to `setGeneric` is allowed in the simple form, but no actual generic function object is created. Method dispatch will take place in the C code. See the section on Primitive Functions for more details.

It’s an important feature that the identical generic function definition is created in every package that uses the same `setGeneric()` call. When any of these packages is loaded into an R session, this function will be added to a table of generic functions, and will contain a methods table of all the available methods for the function.

Calling `setGeneric()` is not strictly necessary before calling `setMethod()`. If the function specified in the call to `setMethod` is not generic, `setMethod` will execute the call to `setGeneric` itself. In the case that the non-generic is in another package, does not dispatch S3 methods and is not a primitive, a message is printed noting the creation of the generic function the first time `setMethod` is called.

The second common use of `setGeneric()` is to create a new generic function, unrelated to any existing function. See the `asRObject()` example below. This case can be handled just like the previous examples, with only the difference that the non-generic function exists in the current package. Again, the non-generic version becomes the default method. For clarity it’s best for the assignment to immediately precede the call to `setGeneric()` in the source code.

Exactly the same result can be obtained by supplying the default as the `def` argument instead of assigning it. In some applications, there will be no completely general default method. While there is a special mechanism for this (see the ‘Specialized Local Generics’ section), the recommendation is to provide a default method that signals an error, but with a message that explains as clearly as you can why a non-default method is needed.

**Specialized Local Generics**

The great majority of calls to `setGeneric()` should either have one argument to ensure that an existing function can have methods, or arguments `name` and `def` to create a new generic function and optionally a default method.

It is possible to create generic functions with nonstandard signatures, or functions that do additional computations besides method dispatch or that belong to a group of generic functions.

None of these mechanisms should be used with a non-generic function from a different package, because the result is to create a generic function that may not be consistent from one package to another. When any such options are used, the new generic function will be assigned with a package slot set to the current package, not the one in which the non-generic version of the function is found.

There is a mechanism to define a specialized generic version of a non-generic function, the `implicitGeneric` construction. This defines the generic version, but then reverts the function to it non-generic form, saving the implicit generic in a table to be activated when methods are defined. However, the mechanism can only legitimately be used either for a non-generic in the same package or by the "methods" package itself. And in the first case, there is no compelling reason not to simply make the function generic, with the non-generic as the default method. See `implicitGeneric` for details.
The body of a generic function usually does nothing except for dispatching methods by a call to `standardGeneric`. Under some circumstances you might just want to do some additional computation in the generic function itself. As long as your function eventually calls `standardGeneric` that is permissible. See the example “authorNames” below.

In this case, the `def` argument will define the nonstandard generic, not the default method. An existing non-generic of the same name and calling sequence should be pre-assigned. It will become the default method, as usual. (An alternative is the `useAsDefault` argument.)

By default, the generic function can return any object. If `valueClass` is supplied, it should be a vector of class names; the value returned by a method is then required to satisfy `is(object, Class)` for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is allowed. Note that more complicated requirements on the result can be specified explicitly, by defining a non-standard generic function.

If the `def` argument calls `standardGeneric()` (with or without additional computations) and there is no existing non-generic version of the function, the generic is created without a default method. This is not usually a good idea: better to have a default method that signals an error with a message explaining why the default case is not defined.

A new generic function can be created belonging to an existing group by including the `group` argument. The argument list of the new generic must agree with that of the group. See `setGroupGeneric` for defining a new group generic. For the role of group generics in dispatching methods, see `GroupGenericFunctions` and section 10.5 of the second reference.

### Generic Functions and Primitive Functions

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an R language definition. Most have implicit generics (see `implicitGeneric`), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Calling `setGeneric()` for the primitive functions in the base package differs in that it does not, in fact, generate an explicit generic function. Methods for primitives are selected and dispatched from the internal C code, to satisfy concerns for efficiency. The same is true for a few non-primitive functions that dispatch internally. These include `unlist` and `as.vector`.

Note, that the implementation restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class. Otherwise the internal C code will not look for methods. This is a desirable restriction in principle, since optional packages should not be allowed to change the behavior of basic R computations on existing data types.

To see the generic version of a primitive function, use `getGeneric(name)`. The function `isGeneric` will tell you whether methods are defined for the function in the current session.

Note that S4 methods can only be set on those primitives which are ‘internal generic’, plus `%^%`.

Examples

## Specify that this package will define methods for plot()
setGeneric("plot")

## create a new generic function, with a default method
setGeneric("props", function(object) attributes(object))

### A non-standard generic function. It insists that the methods
### return a non-empty character vector (a stronger requirement than
### valueClass = "character" in the call to setGeneric)

setGeneric("authorNames",
    function(text) {
        value <- standardGeneric("authorNames")
        if(!is(value, "character") && any(nchar(value)>0))
            stop("authorNames methods must return non-empty strings")
        value
    })

## the asRObject generic function, from package XR
## Its default method just returns object
## See the reference, Chapter 12 for methods
setGeneric("asRObject", function(object, evaluator) {
    object
})

---

setGroupGeneric

Create a Group Generic Version of a Function

Description

The setGroupGeneric function behaves like setGeneric except that it constructs a group generic function, differing in two ways from an ordinary generic function. First, this function cannot be called directly, and the body of the function created will contain a stop call with this information. Second, the group generic function contains information about the known members of the group, used to keep the members up to date when the group definition changes, through changes in the search list or direct specification of methods, etc.

All members of the group must have the identical argument list.

Usage

setGroupGeneric(name, def=, group=list(), valueClass=character(),
    knownMembers=list(), package=, where=)

Arguments

name               the character string name of the generic function.
**setIs**

is an explicit alternative to the contains= argument to setClass. It is only needed to create relations with explicit test or coercion. These have not proved to be of much practical value, so this function should not likely be needed in applications.

Where the programming goal is to define methods for transforming one class of objects to another, it is usually better practice to call setAs(), which requires the transformations to be done explicitly.

**Usage**

```
setIs(class1, class2, test=NULL, coerce=NULL, replace=NULL,
     by = character(), where = topenv(parent.frame()), classDef =,
     extensionObject = NULL, doComplete = TRUE)
```
Arguments

class1, class2  the names of the classes between which is relations are to be examined defined, or (more efficiently) the class definition objects for the classes.

coerce, replace  functions optionally supplied to coerce the object to class2, and to alter the object so that is(object, class2) is identical to value. See the details section below.

test  a conditional relationship is defined by supplying this function. Conditional relations are discouraged and are not included in selecting methods. See the details section below.

The remaining arguments are for internal use and/or usually omitted.

extensionObject  alternative to the test, coerce, replace, by arguments; an object from class SClassExtension describing the relation. (Used in internal calls.)

doComplete  when TRUE, the class definitions will be augmented with indirect relations as well. (Used in internal calls.)

by  In a call to setIs, the name of an intermediary class. Coercion will proceed by first coercing to this class and from there to the target class. (The intermediate coercions have to be valid.)

where  In a call to setIs, where to store the metadata defining the relationship. Default is the global environment for calls from the top level of the session or a source file evaluated there. When the call occurs in the top level of a file in the source of a package, the default will be the namespace or environment of the package. Other uses are tricky and not usually a good idea, unless you really know what you are doing.

classDef  Optional class definition for class, required internally when setIs is called during the initial definition of the class by a call to setClass. Don’t use this argument, unless you really know why you’re doing so.

Details

Arranging for a class to inherit from another class is a key tool in programming. In R, there are three basic techniques, the first two providing what is called “simple” inheritance, the preferred form:

1. By the contains= argument in a call to setClass. This is and should be the most common mechanism. It arranges that the new class contains all the structure of the existing class, and in particular all the slots with the same class specified. The resulting class extension is defined to be simple, with important implications for method definition (see the section on this topic below).

2. Making class1 a subclass of a virtual class either by a call to setClassUnion to make the subclass a member of a new class union, or by a call to setIs to add a class to an existing class union or as a new subclass of an existing virtual class. In either case, the implication should be that methods defined for the class union or other superclass all work correctly for the subclass. This may depend on some similarity in the structure of the subclasses or simply indicate that the superclass methods are defined in terms of generic functions that apply to all the subclasses. These relationships are also generally simple.

3. Supplying coerce and replace arguments to setAs. R allows arbitrary inheritance relationships, using the same mechanism for defining coerce methods by a call to setAs. The difference between the two is simply that setAs will require a call to as for a conversion
to take place, whereas after the call to `setIs`, objects will be automatically converted to the superclass.

The automatic feature is the dangerous part, mainly because it results in the subclass potentially inheriting methods that do not work. See the section on inheritance below. If the two classes involved do not actually inherit a large collection of methods, as in the first example below, the danger may be relatively slight.

If the superclass inherits methods where the subclass has only a default or remotely inherited method, problems are more likely. In this case, a general recommendation is to use the `setAs` mechanism instead, unless there is a strong counter reason. Otherwise, be prepared to override some of the methods inherited.

With this caution given, the rest of this section describes what happens when `coerce=` and `replace=` arguments are supplied to `setIs`.

The `coerce` and `replace` arguments are functions that define how to coerce a `class1` object to `class2`, and how to replace the part of the subclass object that corresponds to `class2`. The first of these is a function of one argument which should be `from`, and the second of two arguments (`from`, `value`). For details, see the section on coerce functions below.

When `by` is specified, the coerce process first coaxes to this class and then to `class2`. It’s unlikely you would use the `by` argument directly, but it is used in defining cached information about classes.

The value returned (invisibly) by `setIs` is the revised class definition of `class1`.

**Coerce, replace, and test functions**

The `coerce` argument is a function that turns a `class1` object into a `class2` object. The `replace` argument is a function of two arguments that modifies a `class1` object (the first argument) to replace the part of it that corresponds to `class2` (supplied as `value`, the second argument). It then returns the modified object as the value of the call. In other words, it acts as a replacement method to implement the expression `as(object, class2) <- value`.

The easiest way to think of the `coerce` and `replace` functions is by thinking of the case that `class1` contains `class2` in the usual sense, by including the slots of the second class. (To repeat, in this situation you would not call `setIs`, but the analogy shows what happens when you do.)

The `coerce` function in this case would just make a `class2` object by extracting the corresponding slots from the `class1` object. The `replace` function would replace in the `class1` object the slots corresponding to `class2`, and return the modified object as its value.

For additional discussion of these functions, see the documentation of the `setAs` function. (Unfortunately, argument `def` to that function corresponds to argument `coerce` here.)

The inheritance relationship can also be conditional, if a function is supplied as the `test` argument. This should be a function of one argument that returns `TRUE` or `FALSE` according to whether the object supplied satisfies the relation `is(object, class2)`. Conditional relations between classes are discouraged in general because they require a per-object calculation to determine their validity. They cannot be applied as efficiently as ordinary relations and tend to make the code that uses them harder to interpret. **NOTE: conditional inheritance is not used to dispatch methods.** Methods for conditional superclasses will not be inherited. Instead, a method for the subclass should be defined that tests the conditional relationship.

**Inherited methods**

A method written for a particular signature (classes matched to one or more formal arguments to the function) naturally assumes that the objects corresponding to the arguments can be treated as coming from the corresponding classes. The objects will have all the slots and available methods for the classes.
The code that selects and dispatches the methods ensures that this assumption is correct. If the inheritance was “simple”, that is, defined by one or more uses of the contains-argument in a call to setClass, no extra work is generally needed. Classes are inherited from the superclass, with the same definition.

When inheritance is defined by a general call to setIs, extra computations are required. This form of inheritance implies that the subclass does not just contain the slots of the superclass, but instead requires the explicit call to the coerce and/or replace method. To ensure correct computation, the inherited method is supplemented by calls to as before the body of the method is evaluated.

The calls to as generated in this case have the argument strict = FALSE, meaning that extra information can be left in the converted object, so long as it has all the appropriate slots. (It’s this option that allows simple subclass objects to be used without any change.) When you are writing your coerce method, you may want to take advantage of that option.

Methods inherited through non-simple extensions can result in ambiguities or unexpected selections. If class2 is a specialized class with just a few applicable methods, creating the inheritance relation may have little effect on the behavior of class1. But if class2 is a class with many methods, you may find that you now inherit some undesirable methods for class1, in some cases, fail to inherit expected methods. In the second example below, the non-simple inheritance from class "factor" might be assumed to inherit S3 methods via that class. But the S3 class is ambiguous, and in fact is "character" rather than "factor".

For some generic functions, methods inherited by non-simple extensions are either known to be invalid or sufficiently likely to be so that the generic function has been defined to exclude such inheritance. For example initialize methods must return an object of the target class; this is straightforward if the extension is simple, because no change is made to the argument object, but is essentially impossible. For this reason, the generic function insists on only simple extensions for inheritance. See the simpleInheritanceOnly argument to setGeneric for the mechanism. You can use this mechanism when defining new generic functions.

If you get into problems with functions that do allow non-simple inheritance, there are two basic choices. Either back off from the setIs call and settle for explicit coercing defined by a call to setAs; or, define explicit methods involving class1 to override the bad inherited methods. The first choice is the safer, when there are serious problems.

Examples

```r
## Two examples of setIs() with coerce= and replace= arguments
## The first one works fairly well, because neither class has many
## inherited methods do be disturbed by the new inheritance

## The second example does NOT work well, because the new superclass,
## "factor", causes methods to be inherited that should not be.

## First example:
## a class definition (see \link{setClass} for class "track")
setClass("trackCurve", contains = "track",
  slots = c( smooth = "numeric"))
## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
  slots = c(x="numeric", y="matrix", smooth="matrix"),
  prototype = structure(list(), x=numeric(), y=matrix(0,0,0),

## Second example:
## a class definition (see \link{setClass} for class "track")
setClass("trackCurve2", contains = "track",
  slots = c( smooth = "numeric"))
## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve2",
  slots = c(x="numeric", y="matrix", smooth="matrix"),
  prototype = structure(list(), x=numeric(), y=matrix(0,0,0),
```
## Automatically convert an object from class "trackCurve" into
## "trackMultiCurve", by making the y, smooth slots into 1-column matrices

```r
setIs("trackCurve",
  "trackMultiCurve",
  coerce = function(obj) {
    new("trackMultiCurve",
    x = obj@x,
    y = as.matrix(obj@y),
    smooth = as.matrix(obj@smooth))
  },
  replace = function(obj, value) {
    obj@y <- as.matrix(value@y)
    obj@x <- value@x
    obj@smooth <- as.matrix(value@smooth)
    obj})
```

## Second Example:
## A class that adds a slot to "character"

```r
setClass("stringsDated", contains = "character",
  slots = c(stamp="POSIXt"))

## Convert automatically to a factor by explicit coerce
setIs("stringsDated", "factor",
  coerce = function(from) factor(from@.Data),
  replace= function(from, value) {
    from@.Data <- as.character(value); from })
```

```r
ll <- sample(letters, 10, replace = TRUE)
ld <- new("stringsDated", ll, stamp = Sys.time())
levels(as(ld, "factor"))
levels(ld) # will be NULL--see comment in section on inheritance above.
```

## In contrast, a class that simply extends "factor"
## has no such ambiguities

```r
setClass("factorDated", contains = "factor",
  slots = c(stamp="POSIXt"))
fd <- new("factorDated", factor(ll), stamp = Sys.time())
identical(levels(fd), levels(as(fd, "factor")))
```

---

### Description

These functions provide a mechanism for packages to specify computations to be done during the loading of a package namespace. Such actions are a flexible way to provide information only available at load time (such as locations in a dynamically linked library).
A call to `setLoadAction()` or `setLoadActions()` specifies one or more functions to be called when the corresponding namespace is loaded, with the ... argument names being used as identifying names for the actions.

`getLoadActions` reports the currently defined load actions, given a package's namespace as its argument.

`hasLoadAction` returns TRUE if a load action corresponding to the given name has previously been set for the where namespace.

`evalOnLoad()` and `evalqOnLoad()` schedule a specific expression for evaluation at load time.

**Usage**

```r
setLoadAction(action, aname=, where=)
setLoadActions(..., .where=)
getLoadActions(where=)
hasLoadAction(aname, where=)
evalOnLoad(expr, where=, aname=)
evalqOnLoad(expr, where=, aname=)
```

**Arguments**

- `action, ...` functions of one or more arguments, to be called when this package is loaded. The functions will be called with one argument (the package namespace) so all following arguments must have default values.
  
  If the elements of ... are named, these names will be used for the corresponding load metadata.

- `where, .where` the namespace of the package for which the list of load actions are defined. This argument is normally omitted if the call comes from the source code for the package itself, but will be needed if a package supplies load actions for another package.

- `aname` the name for the action. If an action is set without supplying a name, the default uses the position in the sequence of actions specified (".1", etc.).

- `expr` an expression to be evaluated in a load action in environment where. In the case of `evalqOnLoad()`, the expression is interpreted literally, in that of `evalOnLoad()` it must be precomputed, typically as an object of type "language".

**Details**

The `evalOnLoad()` and `evalqOnLoad()` functions are for convenience. They construct a function to evaluate the expression and call `setLoadAction()` to schedule a call to that function.

Each of the functions supplied as an argument to `setLoadAction()` or `setLoadActions()` is saved as metadata in the namespace, typically that of the package containing the call to `setLoadActions()`. When this package's namespace is loaded, each of these functions will be called. Action functions are called in the order they are supplied to `setLoadActions()`. The objects assigned have metadata names constructed from the names supplied in the call; unnamed arguments are taken to be named by their position in the list of actions (".1", etc.).
Multiple calls to `setLoadAction()` or `setLoadActions()` can be used in a package’s code; the actions will be scheduled after any previously specified, except if the name given to `setLoadAction()` is that of an existing action. In typical applications, `setLoadActions()` is more convenient when calling from the package’s own code to set several actions. Calls to `setLoadAction()` are more convenient if the action name is to be constructed, which is more typical when one package constructs load actions for another package.

Actions can be revised by assigning with the same name, actual or constructed, in a subsequent call. The replacement must still be a valid function, but can of course do nothing if the intention was to remove a previously specified action.

The functions must have at least one argument. They will be called with one argument, the namespace of the package. The functions will be called at the end of processing of S4 metadata, after dynamically linking any compiled code, the call to `.onLoad()`, if any, and caching method and class definitions, but before the namespace is sealed. (Load actions are only called if methods dispatch is on.)

Functions may therefore assign or modify objects in the namespace supplied as the argument in the call. The mechanism allows packages to save information not available until load time, such as values obtained from a dynamically linked library.

Load actions should be contrasted with user load hooks supplied by `setHook()`. User hooks are generally provided from outside the package and are run after the namespace has been sealed. Load actions are normally part of the package code, and the list of actions is normally established when the package is installed.

Load actions can be supplied directly in the source code for a package. It is also possible and useful to provide facilities in one package to create load actions in another package. The software needs to be careful to assign the action functions in the correct environment, namely the namespace of the target package.

**Value**

`setLoadAction()` and `setLoadActions()` are called for their side effect and return no useful value.

`getLoadActions()` returns a named list of the actions in the supplied namespace.

`hasLoadAction()` returns TRUE if the specified action name appears in the actions for this package.

**See Also**

`setHook` for safer (since they are run after the namespace is sealed) and more comprehensive versions in the base package.

**Examples**

```r
## Not run:
## in the code for some package

## in the code for some package

## ... somewhere else

setLoadActions(function(ns)
  cat("Loaded package", sQuote(getNamespaceName(ns)),
      "at", format(Sys.time()), "\n"),
  function(ns) assign("myCount", 1, envir = ns),
  function(ns) assign("myPointer", getMyExternalPointer(), envir = ns))

... somewhere later

if(countShouldBe0)
  setLoadAction(function(ns) assign("myCount", 0, envir = ns), "setCount")
```
setMethod

Create and Save a Method

Description

Create a method for a generic function, corresponding to a signature of classes for the arguments. Standard usage will be of the form:

```r
setMethod(f, signature, definition)
```

where `f` is the name of the function, `signature` specifies the argument classes for which the method applies and `definition` is the function definition for the method.

Usage

```r
setMethod(f, signature=character(), definition, 
          where = topenv(parent.frame()),
          valueClass = NULL, sealed = FALSE)
```

Arguments

- **f**  
The character-string name of the generic function. The unquoted name usually works as well (evaluating to the generic function), except for a few functions in the base package.

- **signature**  
The classes required for some of the arguments. Most applications just require one or two character strings matching the first argument(s) in the signature. More complicated cases follow R’s rule for argument matching. See the details below; however, if the signature is not trivial, you should use `method.skeleton` to generate a valid call to `setMethod`.

- **definition**  
A function definition, which will become the method called when the arguments in a call to `f` match the classes in `signature`, directly or through inheritance. The definition must be a function with the same formal arguments as the generic; however, `setMethod()` will handle methods that add arguments, if `...` is a formal argument to the generic. See the Details section.

- **where**, **valueClass**, **sealed**

  *These arguments are allowed but either obsolete or rarely appropriate.*

  - **where**: where to store the definition; should be the default, the namespace for the package.
  - **valueClass**: Obsolete.
  - **sealed**: prevents the method being redefined, but should never be needed when the method is defined in the source code of a package.

Value

The function exists for its side-effect. The definition will be stored in a special metadata object and incorporated in the generic function when the corresponding package is loaded into an R session.
**Method Selection: Avoiding Ambiguity**

When defining methods, it’s important to ensure that methods are selected correctly; in particular, packages should be designed to avoid ambiguous method selection.

To describe method selection, consider first the case where only one formal argument is in the active signature; that is, there is only one argument, \( x \) say, for which methods have been defined. The generic function has a table of methods, indexed by the class for the argument in the calls to `setMethod`. If there is a method in the table for the class of \( x \) in the call, this method is selected.

If not, the next best methods would correspond to the direct superclasses of \( \text{class}(x) \)—those appearing in the `contains=` argument when that class was defined. If there is no method for any of these, the next best would correspond to the direct superclasses of the first set of superclasses, and so on.

The first possible source of ambiguity arises if the class has several direct superclasses and methods have been defined for more than one of those; \( R \) will consider these equally valid and report an ambiguous choice. If your package has the class definition for \( \text{class}(x) \), then you need to define a method explicitly for this combination of generic function and class.

When more than one formal argument appears in the method signature, \( R \) requires the “best” method to be chosen unambiguously for each argument. Ambiguities arise when one method is specific about one argument while another is specific about a different argument. A call that satisfies both requirements is then ambiguous: The two methods look equally valid, which should be chosen? In such cases the package needs to add a third method requiring both arguments to match.

The most common examples arise with binary operators. Methods may be defined for individual operators, for special groups of operators such as `Arith` or for group `Ops`.

**Exporting Methods**

If a package defines methods for generic functions, those methods should be exported if any of the classes involved are exported; in other words, if someone using the package might expect these methods to be called. Methods are exported by including an `exportMethods()` directive in the `NAMESPACE` file for the package, with the arguments to the directive being the names of the generic functions for which methods have been defined.

Exporting methods is always desirable in the sense of declaring what you want to happen, in that you do expect users to find such methods. It can be essential in the case that the method was defined for a function that is not originally a generic function in its own package (for example, `plot()` in the `graphics` package). In this case it may be that the version of the function in the \( R \) session is not generic, and your methods will not be called.

Exporting methods for a function also exports the generic version of the function. Keep in mind that this does not conflict with the function as it was originally defined in another package; on the contrary, it’s designed to ensure that the function in the \( R \) session dispatches methods correctly for your classes and continues to behave as expected when no specific methods apply. See `Methods_Details` for the actual mechanism.

**Details**

The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the namespace of a package. In the case of a package, the table object becomes part of the namespace or environment of the package.

When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function "show" from the package "methods". Metadata for methods is identified
by the two strings; in particular, the generic function object itself has slots containing its name
and its package name. The package name of a generic is set according to the package from which
it originally comes; in particular, and frequently, the package where a non-generic version of the
function originated. For example, generic functions for all the functions in package base will have
"base" as the package name, although none of them is an S4 generic on that package. These include
most of the base functions that are primitives, rather than true functions; see the section on primitive
functions in the documentation for setGeneric for details.

Multiple packages can have methods for the same generic function; that is, for the same combination
of generic function name and package name. Even though the methods are stored in separate tables
in separate environments, loading the corresponding packages adds the methods to the table in the
generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as "numeric", "character", and "matrix". Two additional special class names can appear: "ANY", meaning that
this argument can have any class at all; and "missing", meaning that this argument must not appear
in the call in order to match this signature. Don't confuse these two: if an argument isn't mentioned
in a signature, it corresponds implicitly to class "ANY", not to "missing". See the example below.
Old-style ('S3') classes can also be used, if you need compatibility with these, but you should
definitely declare these classes by calling setOldClass if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but only if the generic function
must have some default expression for the same argument. (This restriction is imposed by the way
R manages formal arguments.) If so, and if the corresponding argument is missing in the call to
the generic function, the default expression in the method is used. If the method definition has
no default for the argument, then the expression supplied in the definition of the generic function
itself is used, but note that this expression will be evaluated using the enclosing environment
of the method, not of the generic function. Method selection does not evaluate default expressions.
All actual (non-missing) arguments in the signature of the generic function will be evaluated when
a method is selected—when the call to standardGeneric(f) occurs. Note that specifying class
"missing" in the signature does not require any default expressions.

It is possible to have some differences between the formal arguments to a method supplied to
setMethod and those of the generic. Roughly, if the generic has ... as one of its arguments, then
the method may have extra formal arguments, which will be matched from the arguments matching
... in the call to f. (What actually happens is that a local function is created inside the method, with
the modified formal arguments, and the method is re-defined to call that local function.)
Method dispatch tries to match the class of the actual arguments in a call to the available methods
collected for f. If there is a method defined for the exact same classes as in this call, that method
is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to
superclasses of the actual classes (including "ANY"). The method having the least distance from
the actual classes is chosen; if more than one method has minimal distance, one is chosen (the
lexicographically first in terms of superclasses) but a warning is issued. All inherited methods
chosen are stored in another table, so that the inheritance calculations only need to be done once
per session per sequence of actual classes. See Methods_Details and Section 10.7 of the reference
for more details.

Examples

## examples for a simple class with two numeric slots.
## (Run example(setMethod) to see the class and function definitions)

## methods for plotting track objects
## First, with only one object as argument, plot the two slots
## y must be included in the signature, it would default to "ANY"
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(x@x, x@y, ...)
)

## plot numeric data on either axis against a track object
## (reducing the track object to the cumulative distance along the track)
## Using a short form for the signature, which matches like formal arguments
setMethod("plot", c("track", "numeric"),
  function(x, y, ...) plot(cumdist(x@x, x@y), y, xlab = "Distance",...)
)

## and similarly for the other axis
setMethod("plot", c("numeric", "track"),
  function(x, y, ...) plot(x, cumdist(y@x, y@y), ylab = "Distance",...)
)

 t1 <- new("track", x=1:20, y=(1:20)^2)
plot(t1)
plot(qnorm(ppoints(20)), t1)

## Now a class that inherits from "track", with a vector for data at
## the points
setClass("trackData", contains = c("numeric", "track"))
tc1 <- new("trackData", t1, rnorm(20))

## a method for plotting the object
## This method has an extra argument, allowed because ... is an
## argument to the generic function.
setMethod("plot", c("trackData", "missing"),
  function(x, y, maxRadius = max(par("cin")), ...) {
    plot(x@x, x@y, type = "n", ...)
    symbols(x@x, x@y, circles = abs(x), inches = maxRadius)
  }
)
plot(tc1)

## Without other methods for "trackData", methods for "track"
## will be selected by inheritance
## defining methods for primitive function.
## Although "[" and "length" are not ordinary functions
## methods can be defined for them.
setMethod("[", "track",
    function(x, i, j, ..., drop) {
      x@x <- x@x[i]; x@y <- x@y[i]
      x
    })
plot(t1[1:15])

setMethod("length", "track", function(x)length(x@y))
length(t1)

## Methods for binary operators
## A method for the group generic "Ops" will apply to all operators
## unless a method for a more specific operator has been defined.
## For one trackData argument, go on with just the data part
setMethod("Ops", signature(e1 = "trackData"),
    function(e1, e2) callGeneric(e1@.Data, e2))
setMethod("Ops", signature(e2 = "trackData"),
    function(e1, e2) callGeneric(e1, e2@.Data))

## At this point, the choice of a method for a call with BOTH
## arguments from "trackData" is ambiguous. We must define a method.
setMethod("Ops", signature(e1 = "trackData", e2 = "trackData"),
    function(e1, e2) callGeneric(e1@.Data, e2@.Data))

## (well, really we should only do this if the "track" part
## of the two arguments matched)
tc1 +1

1/tc1

all(tc1 == tc1)

---

**setOldClass**

Register Old-Style (S3) Classes and Inheritance

### Description

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. Simple usage will be of the form:

```r
setOldClass(Calsses)
```

where `Classes` is the character vector that would be the `class` attribute of the S3 object. Calls to `setOldClass()` in the code for a package allow the class to be used as a slot in formal (S4) classes and in signatures for methods (see `Methods_for_S3`). Formal classes can also contain a registered S3 class (see `S3Part` for details).
If the S3 class has a known set of attributes, an equivalent S4 class can be specified by `S4Class=` in the call to `setOldClass()`; see the section “Known Attributes”.

**Usage**

```r
setOldClass(Class, prototype, where, test = FALSE, S4Class)
```

**Arguments**

- **Classes**: A character vector, giving the names for S3 classes, as they would appear on the right side of an assignment of the `class` attribute in S3 computations.
  
  In addition to S3 classes, an object type or other valid data part can be specified, if the S3 class is known to require its data to be of that form.

- **S4Class**: optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus any S3 inheritance implied by multiple names in the `Classes` argument. See the section on “S3 classes with known attributes” below.

- **prototype, where, test**: These arguments are currently allowed, but not recommended in typical applications.
  
  - **prototype**: An optional object to use as the prototype. If the S3 class is not to be VIRTUAL (the default), the use of `S4Class=` is preferred.
  
  - **where**: Where to store the class definitions. Should be the default (the package namespace) for normal use in an application package.
  
  - **test**: flag, if TRUE, arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. Such classes are inherently malformed, are rare, and should be avoided.

**Details**

The name (or each of the names) in `Classes` will be defined as an S4 class, extending class `oldClass`, which is the ‘root’ of all old-style classes. S3 classes with multiple names in their class attribute will have a corresponding inheritance as formal classes. See the “mlm” example.

S3 classes have no formal definition, and therefore no formally defined slots. If no S4 class is supplied as a model, the class created will be a virtual class. If a virtual class (any virtual class) is used for a slot in another class, then the initializing method for the class needs to put something legal in that slot; otherwise it will be set to `NULL`.

See **Methods_for_S3** for the details of method dispatch and inheritance with mixed S3 and S4 methods.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects with the same initial string in the class attribute can have different strings following. Such classes are fortunately rare. They violate the basic idea of object-oriented programming and should be avoided. If you must deal with them, it is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call `setOldClass` with argument `test=TRUE`.

**Pre-Defined Old Classes**

Many of the widely used S3 classes in the standard R distribution come pre-defined for use with S4. These don’t need to be explicitly declared in your package (although it does no harm to do so).
The list `.OldClassesList` contains the old-style classes that are defined by the methods package. Each element of the list is a character vector, with multiple strings if inheritance is included. Each element of the list was passed to `setOldClass` when creating the `methods` package; therefore, these classes can be used in `setMethod` calls, with the inheritance as implied by the list.

### S3 Classes with known attributes

A further specification of an S3 class can be made if the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to `setOldClass()` can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument `S4Class=` to `setOldClass()`.

See the definition of class "ts" in the examples below and the `data.frame` example in Section 10.2 of the reference. The call to `setClass` to create the S4 class can use the same class name, as here, so long as the call to `setOldClass` follows in the same package. For clarity it should be the next expression in the same file.

In the example, we define "ts" as a vector structure with a numeric slot for "tsp". The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all "ts" objects will behave as vector structures and will have a numeric "tsp" attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the "ts" case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the `structure` class).

Failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of the attributes are not guaranteed (e.g., `dimnames` in arrays, although these are not even S3 classes), or because the class uses named components of a list rather than attributes (e.g., "lm"). An attribute that is sometimes missing cannot be represented as a slot, not even by pretending that it is present with class "NULL", because attributes, unlike slots, can not have value `NULL`.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those guaranteed to exist (for example, "terms" in "data.frame" objects returned by `model.frame`). Validity checks by `validObject` ignore extra attributes; even if this check is tightened in the future, classes extending S3 classes would likely be exempted because extra attributes are so common.

### Examples

```r
require(stats)
```
## "lm" and "mlm" are predefined; if they were not this would do it:
## Not run:
setOldClass(c("mlm", "lm"))
## End(Not run)

## Define a new generic function to compute the residual degrees of freedom
setGeneric("dfResidual",
  function(model) stop(gettextf(
    "This function only works for fitted model objects, not class %s",
    class(model))))
setMethod("dfResidual", "lm", function(model) model$df.residual)

## dfResidual will work on mlm objects as well as lm objects
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)

## two examples extending S3 class "lm": class "xlm" directly
## and "ylm" indirectly
setClass("xlm", slots = c(eps = "numeric"), contains = "lm")
setClass("ylm", slots = c(header = "character"), contains = "xlm")
yn1 = new("ylm", myLm, header = "Example", eps = 0.)
## for more examples, see ?\link{S3Class}.

## Not run:
## The code in R that defines "ts" as an S4 class
setClass("ts", contains = "structure", slots = c(tsp = "numeric"),
  prototype(NA, tsp = rep(1,3)))
  # prototype to be a legal S3 time-series
## and now registers it as an S3 class
setOldClass("ts", S4Class = "ts", where = envir)
## End(Not run)

---

### Description

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls `showDefault`.

Formal methods for `show` will usually be invoked for automatic printing (see the details).

### Usage

```r
show(object)
```
Arguments

object Any R object

Details

Objects from an S4 class (a class defined by a call to setClass) will be displayed automatically is if by a call to show. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to print.

Methods defined for show will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the simpleInheritanceOnly argument to setGeneric and the discussion in setIs for the general concept.

Value

show returns an invisible NULL.

See Also

showMethods prints all the methods for one or more functions.

Examples

## following the example shown in the setMethod documentation ...
setClass("track", slots = c(x="numeric", y="numeric"))
setClass("trackCurve", contains = "track", slots = c(smooth = "numeric"))
t1 <- new("track", x=1:20, y=(1:20)^2)
tc1 <- new("trackCurve", t1)

setMethod("show", "track",
  function(object)print(rbind(x = object@x, y=object@y))
)

## The method will now be used for automatic printing of t1

t1

## Not run: x 1 2 3 4 5 6 7 8 9 10 11 12
## Not run: y 1 4 9 16 25 36 49 64 81 100 121 144

## Not run: x 13 14 15 16 17 18 19 20
## Not run: y 169 196 225 256 289 324 361 400

## End(Not run)

## and also for tc1, an object of a class that extends "track"
tc1

## Not run: x 1 2 3 4 5 6 7 8 9 10 11 12
## Not run: y 1 4 9 16 25 36 49 64 81 100 121 144

## Not run: x 13 14 15 16 17 18 19 20
## Not run: y 169 196 225 256 289 324 361 400

## End(Not run)
showMethods

Show all the methods for the specified function(s) or class

Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

Usage

showMethods(f = character(), where = topenv(parent.frame())),
classes = NULL, includeDefs = FALSE,
inherited = !includeDefs,
showEmpty, printTo = stdout(), fdef)
.S4methods(generic.function, class)

Arguments

f  one or more function names. If omitted, all functions will be shown that match the other arguments.
The argument can also be an expression that evaluates to a single generic function, in which case argument fdef is ignored. Providing an expression for the function allows examination of hidden or anonymous functions; see the example for isDiagonal().

where  Where to find the generic function, if not supplied as an argument. When f is missing, or length 0, this also determines which generic functions to examine. If where is supplied, only the generic functions returned by getGenerics(where) are eligible for printing. If where is also missing, all the cached generic functions are considered.

classes  If argument classes is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.

includeDefs  If includeDefs is TRUE, include the definitions of the individual methods in the printout.

inherited  logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See selectMethod if you want to know what method would be dispatched for particular classes of arguments.

showEmpty  logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, TRUE if and only if argument f is not missing.

printTo  The connection on which the information will be shown; by default, on standard output.
showMethods

fdef  Optionally, the generic function definition to use; if missing, one is found, looking in where if that is specified. See also comment in ‘Details’.

generic.function, class
  See methods.

Details

See methods for a description of .S4methods.

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because f was missing, the functions are found and showMethods is recalled for each, including the generic as the argument fdef. In complicated situations, this can avoid some anomalous results.

Value

If printTo is FALSE, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via invisible.

See Also

setMethod, and GenericFunctions for other tools involving methods; selectMethod will show you the method dispatched for a particular function and signature of classes for the arguments.

methods provides method discovery tools for light-weight interactive use.

Examples

require(graphics)

## Assuming the methods for plot
## are set up as in the example of help(setMethod),
## print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
## Not run:
# Function "plot":
# x = ANY, y = track
# x = track, y = missing
# x = track, y = ANY

require("Matrix")
showMethods("%*%") # many!
  methods(class = "Matrix") # nothing
showMethods(class = "Matrix") # everything
showMethods(Matrix:::isDiagonal) # a non-exported generic

## End(Not run)
signature-class

```
if(no4 <- is.na(match("stats4", loadedNamespaces())))
  loadNamespace("stats4")
showMethods(classes = "mle") # -> a method for show()
if(no4) unloadNamespace("stats4")
```

---

**signature-class**  
*Class "signature" For Method Definitions*

### Description

This class represents the mapping of some of the formal arguments of a function onto the corresponding classes. It is used for two slots in the `MethodDefinition` class.

### Objects from the Class

Objects can be created by calls of the form `new("signature", functionDef, ...)`. The `functionDef` argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes. More typically, the objects are created as side effects of defining methods. Either way, note that the classes are expected to be well defined, usually because the corresponding class definitions exist. See the comment on the `package` slot.

### Slots

- `.Data`: Object of class "character" the class names.
- `names`: Object of class "character" the corresponding argument names.
- `package`: Object of class "character" the names of the packages corresponding to the class names. The combination of class name and package uniquely defines the class. In principle, the same class name could appear in more than one package, in which case the package information is required for the signature to be well defined.

### Extends

Class "character", from data part. Class "vector", by class "character".

### Methods

- `initialize signature(object = "signature")`: see the discussion of objects from the class, above.

### See Also

class `MethodDefinition` for the use of this class.
**Description**

These functions return or set information about the individual slots in an object.

**Usage**

```r
object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value
.hasSlot(object, name)

slotNames(x)
getSlots(x)
```

**Arguments**

- `object` - An object from a formally defined class.
- `name` - The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and .., it needs to be quoted (by backticks or single or double quotes).
  - In the case of the `slot` function, `name` can be any expression that evaluates to a valid slot in the class definition. Generally, the only reason to use the functional form rather than the simpler operator is because the slot name has to be computed.
- `value` - A new value for the named slot. The value must be valid for this slot in this object's class.
- `check` - In the replacement version of `slot`, a flag. If TRUE, check the assigned value for validity as the value of this slot. User’s coded should not set this to FALSE in normal use, since the resulting object can be invalid.
- `x` - either the name of a class (as character string), or a class definition. If given an argument that is neither a character string nor a class definition, `slotNames` (only) uses `class(x)` instead.

**Details**

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

The `@` extraction operator and `slot` function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for `slot` in the case `check=FALSE`). So long as slots are set without cheating, the extracted slots will be valid.
Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious way is to assign a slot with check=FALSE. Also, slots in R are implemented as attributes, for the sake of some back compatibility. The current implementation does not prevent attributes being assigned, via attr<-., and such assignments are not checked for legitimate slot names.

Note that the "@" operators for extraction and replacement are primitive and actually reside in the base package.

The replacement versions of "@" and slot() differ in the computations done to coerce the right side of the assignment to the declared class of the slot. Both verify that the value provided is from a subclass of the declared slot class. The slot() version will go on to call the coerce method if there is one, in effect doing the computation as(value, slotClass, strict = FALSE). The "@" version just verifies the relation, leaving any coerce to be done later (e.g., when a relevant method is dispatched).

In most uses the result is equivalent, and the "@" version saves an extra function call, but if empirical evidence shows that a conversion is needed, either call as() before the replacement or use the replacement version of slot().

Value

The "@" operator and the slot function extract or replace the formally defined slots for the object.

Functions slotNames and getSlots return respectively the names of the slots and the classes associated with the slots in the specified class definition. Except for its extended interpretation of x (above), slotNames(x) is just names(getSlots(x)).

Examples

```r
setClass("track", slots = c(x="numeric", y="numeric"))
myTrack <- new("track", x = -4:4, y = exp(-4:4))
slot(myTrack, "x")
slot(myTrack, "y") <- log(slot(myTrack, "y"))
utils::str(myTrack)

getSlots("track") # or
getSlots(getClass("track"))
slotNames(class(myTrack)) # is the same as
slotNames(myTrack)
```
StructureClasses

Classes Corresponding to Basic Structures

Description

The virtual class `structure` and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.

Usage

```r
## The following class names can appear in method signatures,
## as the class in as() and is() expressions, and, except for
## the classes commented as VIRTUAL, in calls to new()
"matrix"
"array"
"ts"

"structure" # VIRTUAL
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., "matrix"), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., to function `matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes "matrix" and "array" are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no "class" attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return `FALSE` for such objects). However, methods (both S4 and S3) can be defined for these pseudo-classes and new classes (both S4 and S3) can inherit from them.

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the special treatment is that these two classes `may` be used as the data part of an S4 class; for example, you can get away with `contains = "matrix"` in a call to `setGeneric` to create an S4 class that is a subclass of "matrix". There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

Note that a class containing "matrix" or "array" will have a `.Data` slot with that class. This is the only use of `.Data` other than as a pseudo-class indicating the type of the object. In this case the type of the object will be the type of the contained matrix or array. See `Classes_Details` for a general discussion.

The class "ts" is basically an S3 class that has been registered with S4, using the `setOldClass` mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems. (For example, setting the "tsp" parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class "mts".)
Time-series objects, in contrast to matrices and arrays, have a valid S3 class, "ts", registered using an S4-style definition (see the documentation for `setOldClass` in the examples section for an abbreviated listing of how this is done. The S3 inheritance of "mts" in package `stats` is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

All of these classes have special S4 methods for `initialize` that accept the same arguments as the basic generator functions, `matrix`, `array`, and `ts`, in so far as possible. The limitation is that a class that has more than one non-virtual superclass must accept objects from that superclass in the call to `new`; therefore, a such a class (what is called a “mixin” in some languages) uses the default method for `initialize`, with no special arguments.

**Extends**

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

**Methods**

- **coerce** Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "matrix")` calls `as.matrix(x)`. If `strict = TRUE` in the call to `as()`, the method goes on to delete all other slots and attributes other than the `dim` and `dimnames`.

- **Ops** Group methods (see, e.g., `S4groupGeneric`) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference. Essentially, structures combined with vectors retain the structure as long as the resulting object has the same length. Structures combined with other structures remove the structure, since there is no automatic way to determine what should happen to the slots defining the structure.

  Note that these methods will be activated when a package is loaded containing a class that inherits from any of the structure classes or class "vector".

**References**

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

**See Also**

Class `nonStructure`, which enforces the alternative model, in which all slots are dropped if any math transformation or operation is applied to an object from a class extending one of the basic classes.

**Examples**

```r
showClass("structure")

# explore a bit :
showClass("ts")
(ts0 <- new("ts"))
str(ts0)
```
testInheritedMethods

Test for and Report about Selection of Inherited Methods

Description

A set of distinct inherited signatures is generated to test inheritance for all the methods of a specified
generic function. If method selection is ambiguous for some of these, a summary of the ambiguities
is attached to the returned object. This test should be performed by package authors before releasing
a package.

Usage

testInheritedMethods(f, signatures, test = TRUE, virtual = FALSE,
groupMethods = TRUE, where = .GlobalEnv)

Arguments

f
a generic function or the character string name of one. By default, all currently
defined subclasses of all the method signatures for this generic will be examined.
The other arguments are mainly options to modify which inheritance patterns
will be examined.

signatures
An optional set of subclass signatures to use instead of the relevant subclasses
computed by testInheritedMethods. See the Details for how this is done.
This argument might be supplied after a call with test = FALSE, to test selection
in batches.

test
optional flag to control whether method selection is actually tested. If FALSE, returns just the list of relevant
signatures for subclasses, without calling selectMethod for each signature. If there are a very large number of
signatures, you may want to collect the full list and then test them in batches.

virtual
should virtual classes be included in the relevant subclasses. Normally not, since
only the classes of actual arguments will trigger the inheritance calculation in a
call to the generic function. Including virtual classes may be useful if the class
has no current non-virtual subclasses but you anticipate your users may define
such classes in the future.

groupMethods
should methods for the group generic function be included?

where
the environment in which to look for class definitions. Nearly always, use the
default global environment after attaching all the packages with relevant meth-
ods and/or class definitions.

Details

The following description applies when the optional arguments are omitted, the usual case. First,
the defining signatures for all methods are computed by calls to findMethodSignatures. From
these all the known non-virtual subclasses are found for each class that appears in the signature of
some method. These subclasses are split into groups according to which class they inherit from,
and only one subclass from each group is retained (for each argument in the generic signature).
So if a method was defined with class "vector" for some argument, one actual vector class is
chosen arbitrarily. The case of "ANY" is dealt with specially, since all classes extend it. A dummy,
nonvirtual class, ".Other", is used to correspond to all classes that have no superclasses among those being tested.

All combinations of retained subclasses for the arguments in the generic signature are then computed. Each row of the resulting matrix is a signature to be tested by a call to `selectMethod`. To collect information on ambiguous selections, `testInheritedMethods` establishes a calling handler for the special signal "ambiguousMethodSelection", by setting the corresponding option.

**Value**

An object of class "methodSelectionReport". The details of this class are currently subject to change. It has slots "target", "selected", "candidates", and "note", all referring to the ambiguous cases (and so of length 0 if there were none). These slots are intended to be examined by the programmer to detect and preferably fix ambiguous method selections. The object contains in addition slots "generic", the name of the generic function, and "allSelections", giving the vector of labels for all the signatures tested.

**References**

**Examples**

```r
## if no other attached packages have methods for '+\' or its group
## generic functions, this returns a 16 by 2 matrix of selection
## patterns (in R 2.9.0)
##
testInheritedMethods("+")
```

---

**TraceClasses**

*Classes Used Internally to Control Tracing*

**Description**

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.

**Usage**

```r
### Objects from the following classes are generated
### by calling trace() on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"

**Objects from the Class**

Objects will be created from these classes by calls to `trace`. (There is an `initialize` method for class "traceable", but you are unlikely to need it directly.)

**Slots**

.Data: The data part, which will be "function" for class "functionWithTrace", and similarly for the other classes.

original: Object of the original class; e.g., "function" for class "functionWithTrace".

**Extends**

Each of the classes extends the corresponding untraced class, from the data part; e.g., "functionWithTrace" extends "function". Each of the specific classes extends "traceable", directly, and class "VIRTUAL", by class "traceable".

**Methods**

The point of the specific classes is that objects generated from them, by function `trace()`, remain callable or dispatchable, in addition to their new trace information.

**See Also**

function `trace`

---

**validObject**

*Test the Validity of an Object*

**Description**

`validObject()` tests the validity of object related to its class definition; specifically, it checks that all slots specified in the class definition are present and that the object in the slot is from the required class or a subclass of that class.

If the object is valid, TRUE is returned; otherwise, an error is generated, reporting all the validity failures encountered. If argument `test` is TRUE, the errors are returned as a character vector rather than generating an error.

When an object from a class is initialized, the default method for `initialize()` calls `validObject`.

A class definition may have a validity method, set by a call to the function `setValidity`, in the package or environment that defines the class (or via the validity argument to `setClass`). The method should be a function of one object that returns TRUE or a character-string description of the non-validity. If such a method exists, it will be called from `validObject` and any strings from failure will be included in the result or the error message. Any validity methods defined for superclasses (from the contains= argument to `setClass`) will also be called.
validObject

Usage

validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = topenv(parent.frame()) )

getValidity(ClassDef)

Arguments

object any object, but not much will happen unless the object’s class has a formal definition.
test logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.
complete logical; if TRUE, validObject is called recursively for each of the slots. The default is FALSE.
Class the name or class definition of the class whose validity method is to be set.
ClassDef a class definition object, as from getClassDef.
method a validity method; that is, either NULL or a function of one argument (object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.
where an environment to store the modified class definition. Should be omitted, specifically for calls from a package that defines the class. The definition will be stored in the namespace of the package.

Details

Validity testing takes place ‘bottom up’, checking the slots, then the superclasses, then the object’s own validity method, if there is one.

For each slot and superclass, the existence of the specified class is checked. For each slot, the object in the slot is tested for inheritance from the corresponding class. If complete is TRUE, validObject is called recursively for the object in the slot.

Then, for each of the classes that this class extends (the ‘superclasses’), the explicit validity method of that class is called, if one exists. Finally, the validity method of object’s class is called, if there is one.

Value

validObject returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if test is FALSE, validity failure generates an error, with the corresponding strings in the error message.

Validity methods

A validity method must be a function of one argument; formally, that argument should be named object. If the argument has a different name, setValidity makes the substitution but in obscure cases that might fail, so it’s wiser to name the argument object.

A good method checks all the possible errors and returns a character vector citing all the exceptions found, rather than returning after the first one. validObject will accumulate these errors in its error message or its return value.
Note that validity methods do not have to check validity of superclasses: `validObject` calls such methods explicitly.

**References**

**See Also**

`setClass`; `class`, `classRepresentation`.

**Examples**

```r
defineNamespace()

validObject

setClass("track",
  slots = c(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
  if(length(object@x) == length(object@y)) TRUE
  else paste0("Unequal x,y lengths: ", length(object@x), ", ",
               length(object@y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validTrackObject)
## t1 should be a valid "track" object
validObject(t1)
## Now we do something bad

t2 <- t1
t2@x <- 1:20
## This should generate an error
## Not run: try(validObject(t2))

setClass("trackCurve", contains = "track",
  slots = c(smooth = "numeric"))
## all superclass validity methods are used when validObject
## is called from initialize() with arguments, so this fails
## Not run: trynew("trackCurve", t2)

setClass("twoTrack", slots = c(tr1 = "track", tr2 ="track"))
## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)
## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))
```
Chapter 8

The parallel package

parallel-package  Support for Parallel Computation

Description

Support for parallel computation, including random-number generation.

Details

This package was first included with R 2.14.0 in 2011.

There is support for multiple RNG streams with the ‘"L'Ecuyer-CMRG’’ RNG: see nextRNGStream.

It contains functionality derived from and pretty much equivalent to that contained in packages multicore (formerly on CRAN, with some low-level functions renamed and not exported) and snow (for socket clusters only, but MPI and NWS clusters generated by snow are also supported). There have been many enhancements and bug fixes since 2011.

This package also provides makeForkCluster to create socket clusters by forking (not Windows).

For a complete list of exported functions, use library(help = "parallel").

Author(s)

Brian Ripley, Luke Tierney and Simon Urbanek

Maintainer: R Core Team <R-core@r-project.org>

See Also

Parallel computation involves launching worker processes: functions psnice and pskill in package tools provide means to manage such processes.
Apply Operations using Clusters

Description

These functions provide several ways to parallelize computations using a cluster.

Usage

clusterCall(cl = NULL, fun, ...)
clusterApply(cl = NULL, x, fun, ...)
clusterApplyLB(cl = NULL, x, fun, ...)
clusterEvalQ(cl = NULL, expr)
clusterExport(cl = NULL, varlist, envir = .GlobalEnv)
clusterMap(cl = NULL, fun, ..., MoreArgs = NULL, RECYCLE = TRUE,
  SIMPLIFY = FALSE, USE.NAMES = TRUE,
  .scheduling = c("static", "dynamic"))
clusterSplit(cl = NULL, seq)
parLapply(cl = NULL, X, fun, ...)
parSapply(cl = NULL, X, FUN, ..., simplify = TRUE,
  USE.NAMES = TRUE)
parApply(cl = NULL, X, MARGIN, FUN, ...)
parRapply(cl = NULL, x, FUN, ...)
parCapply(cl = NULL, x, FUN, ...)
parLapplyLB(cl = NULL, X, fun, ...)
parSapplyLB(cl = NULL, X, FUN, ..., simplify = TRUE,
  USE.NAMES = TRUE)

Arguments

cl  a cluster object, created by this package or by package snow. If NULL, use the
geristered default cluster.
fun, FUN function or character string naming a function.
expr expression to evaluate.
seq vector to split.
varlist character vector of names of objects to export.
envir environment from which t export variables
x a vector for clusterApply and clusterApplyLB, a matrix for parRapply and
  parCapply.
... additional arguments to pass to fun or FUN: beware of partial matching to earlier
  arguments.
MoreArgs additional arguments for fun.
RECYCLE logical; if true shorter arguments are recycled.
X A vector (atomic or list) for parLapply and parSapply, an array for parApply.
MARGIN vector specifying the dimensions to use.
clusterApply

simplify, USE.NAMES
  logical; see sapply.
SIMPLIFY logical; see mapply.

.scheduling should tasks be statically allocated to nodes or dynamic load-balancing used?

Details

clusterCall calls a function fun with identical arguments ... on each node.
clusterEvalQ evaluates a literal expression on each cluster node. It is a parallel version of evalq, and is a convenience function invoking clusterCall.
clusterApply calls fun on the first node with arguments x[[1]] and ..., on the second node with x[[2]] and ..., and so on, recycling nodes as needed.
clusterApplyLB is a load balancing version of clusterApply. If the length n of x is not greater than the number of nodes p, then a job is sent to n nodes. Otherwise the first p jobs are placed in order on the p nodes. When the first job completes, the next job is placed on the node that has become free; this continues until all jobs are complete. Using clusterApplyLB can result in better cluster utilization than using clusterApply, but increased communication can reduce performance. Furthermore, the node that executes a particular job is non-deterministic.
clusterMap is a multi-argument version of clusterApply, analogous to mapply and Map. If RECYCLE is true shorter arguments are recycled (and either none or all must be of length zero); otherwise, the result length is the length of the shortest argument. Nodes are recycled if the length of the result is greater than the number of nodes. (mapply always uses RECYCLE = TRUE, and has argument SIMPLIFY = TRUE. Map always uses RECYCLE = TRUE.)
clusterExport assigns the values on the master R process of the variables named in varlist to variables of the same names in the global environment (aka ‘workspace’) of each node. The environment on the master from which variables are exported defaults to the global environment.
clusterSplit splits seq into a consecutive piece for each cluster and returns the result as a list with length equal to the number of nodes. Currently the pieces are chosen to be close to equal in length: the computation is done on the master.
parLapply, parSapply, and parApply are parallel versions of lapply, sapply and apply. parLapplyLB, parSapplyLB are load-balancing versions, intended for use when applying FUN to different elements of X takes quite variable amounts of time, and either the function is deterministic or reproducible results are not required.
parRapply and parCapply are parallel row and column apply functions for a matrix x; they may be slightly more efficient than parApply but do less post-processing of the result.

Value

For clusterCall, clusterEvalQ and clusterSplit, a list with one element per node.
For clusterApply and clusterApplyLB, a list the same length as x.
clusterMap follows mapply.
clusterExport returns nothing.
parLapply returns a list the length of X.
parSapply and parApply follow sapply and apply respectively.
parRapply and parCapply always return a vector. If FUN always returns a scalar result this will be of length the number of rows or columns: otherwise it will be the concatenation of the returned values.
An error is signalled on the master if any of the workers produces an error.
Note

These functions are almost identical to those in package `snow`.

Two exceptions: `parLapply` has argument `X` not `x` for consistency with `lapply`, and `parSapply` has been updated to match `sapply`.

Author(s)

Luke Tierney and R Core.

Derived from the `snow` package.

Examples

```r
## Use option cl.cores to choose an appropriate cluster size.
cl <- makeCluster(getOption("cl.cores", 2))

clusterApply(cl, 1:2, get("+") , 3)
xx <- 1
clusterExport(cl, "xx")
clusterCall(cl, function(y) xx + y, 2)

## Use clusterMap like an mapply example
clusterMap(cl, function(x, y) seq_len(x) + y,
           c(a = 1, b = 2, c = 3), c(A = 10, B = 0, C = -10))

parSapply(cl, 1:20, get("+") , 3)

## A bootstrapping example, which can be done in many ways:
clusterEvalQ(cl, {
  ## set up each worker. Could also use clusterExport()
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvnrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  NULL
})
res <- clusterEvalQ(cl, boot(cd4, corr, R = 100,
           sim = "parametric", ran.gen = cd4.rg, mle = cd4.mle))

library(boot)
bd4.boot <- do.call(c, res)
boot.ci(bd4.boot, type = c("norm", "basic", "perc"),
        conf = 0.9, h = atanh, hinv = tanh)
stopCluster(cl)

## or
library(boot)
run1 <- function(...) {
  library(boot)
  cd4.rg <- function(data, mle) MASS::mvnrnorm(nrow(data), mle$m, mle$v)
  cd4.mle <- list(m = colMeans(cd4), v = var(cd4))
  boot(cd4, corr, R = 500, sim = "parametric",
       ran.gen = cd4.rg, mle = cd4.mle)
}
cl <- makeCluster(mc <- getOption("cl.cores", 2))
## to make this reproducible
clusterSetRNGStream(cl, 123)
```
**detectCores**

Detect the Number of CPU Cores

**Description**

Attempt to detect the number of CPU cores on the current host.

**Usage**

```r
detectCores(all.tests = FALSE, logical = TRUE)
```

**Arguments**

- `all.tests` Logical: if true apply all known tests.
- `logical` Logical: if possible, use the number of physical CPUs/cores (if FALSE) or logical CPUs (if TRUE). Currently this is honoured only on macOS, Solaris and Windows.

**Details**

This attempts to detect the number of available CPU cores.

It has methods to do so for Linux, macOS, FreeBSD, OpenBSD, Solaris, Irix and Windows. `detectCores(TRUE)` could be tried on other Unix-alike systems.

**Value**

An integer, NA if the answer is unknown.

Exactly what this represents is OS-dependent: where possible by default it counts logical (e.g., hyperthreaded) CPUs and not physical cores or packages.

Under macOS there is a further distinction between ‘available in the current power management mode’ and ‘could be available this boot’, and this function returns the first.

On Sparc Solaris `logical = FALSE` returns the number of physical cores and `logical = TRUE` returns the number of available hardware threads. (Some Sparc CPUs have multiple cores per CPU, others have multiple threads per core and some have both.) For example, the Ultra-Sparc T2 CPU in the former CRAN check server was a single physical CPU with 8 cores, and each core supports 8 hardware threads. So `detectCores(logical = FALSE)` returns 8, and `detectCores(logical = TRUE)` returns 64.

Where virtual machines are in use, one would hope that the result for `logical = TRUE` represents the number of CPUs available (or potentially available) to that particular VM.

**Note**

This is not suitable for use directly for the `mc.cores` argument of `mclapply` nor specifying the number of cores in `makeCluster`. First because it may return NA, second because it does not give the number of *allowed* cores, and third because on Sparc Solaris and some Windows boxes it is not reasonable to try to use all the logical CPUs at once.
Author(s)
Simon Urbanek and Brian Ripley

Examples

detectCores()
detectCores(logical = FALSE)

Description
Creates a set of copies of R running in parallel and communicating over sockets.

Usage

makeCluster(spec, type, ...)
makePSOCKcluster(names, ...)
makeForkCluster(nnodes = getOption("mc.cores", 2L), ...)

stopCluster(cl = NULL)
setDefaultCluster(cl = NULL)
getDefaultCluster()

Arguments
spec A specification appropriate to the type of cluster.
names Either a character vector of host names on which to run the worker copies of R, or a positive integer (in which case that number of copies is run on 'localhost').
nnodes The number of nodes to be forked.
type One of the supported types: see 'Details'.
... Options to be passed to the function spawning the workers. See 'Details'.
cl an object of class "cluster".

Details
makeCluster creates a cluster of one of the supported types. The default type, "PSOCK", calls makePSOCKcluster. Type "FORK" calls makeForkCluster. Other types are passed to package snow.

makePSOCKcluster is an enhanced version of makeSOCKcluster in package snow. It runs Rscript on the specified host(s) to set up a worker process which listens on a socket for expressions to evaluate, and returns the results (as serialized objects).

makeForkCluster is merely a stub on Windows. On Unix-alike platforms it creates the worker process by forking.

The workers are most often running on the same host as the master, when no options need be set. Several options are supported (mainly for makePSOCKcluster):
master The host name of the master, as known to the workers. This may not be the same as it is known to the master, and on private subnets it may be necessary to specify this as a numeric IP address. For example, macOS is likely to detect a machine as ‘somename.local’, a name known only to itself.

port The port number for the socket connection, default taken from the environment variable R_PARALLEL_PORT, then a randomly chosen port in the range 11000:11999.

timeout The timeout in seconds for that port. Default 30 days (and the POSIX standard only requires values up to 31 days to be supported).

outfile Where to direct the stdout and stderr connection output from the workers. "" indicates no redirection (which may only be useful for workers on the local machine). Defaults to '/dev/null' ('nul:' on Windows). The other possibility is a file path on the worker's host. Files will be opened in append mode, as all workers log to the same file.

homogeneous Logical. Are all the hosts running identical setups, so Rscript can be launched using the same path on each? Otherwise Rscript has to be in the default path on the workers.

rscript The path to Rscript on the workers, used if homogeneous is true. Defaults to the full path on the master.

rscript_args Character vector of additional arguments for Rscript such as '--no-environ'.

renice A numerical 'niceness' to set for the worker processes, e.g. 15 for a low priority. OS-dependent: see psnice for details.

rshcmd The command to be run on the master to launch a process on another host. Defaults to ssh.

user The user name to be used when communicating with another host.

manual Logical. If true the workers will need to be run manually.

methods Logical. If true (default) the workers will load the methods package: not loading it saves ca 30% of the startup CPU time of the cluster.

useXDR Logical. If true (default) serialization will use XDR: where large amounts of data are to be transferred and all the nodes are little-endian, communication may be substantially faster if this is set to false.

Function makeForkCluster creates a socket cluster by forking (and hence is not available on Windows). It supports options port, timeout and outfile, and always uses useXDR = FALSE.

It is good practice to shut down the workers by calling stopCluster: however the workers will terminate themselves once the socket on which they are listening for commands becomes unavailable, which it should if the master R session is completed (or its process dies).

Function setDefaultCluster registers a cluster as the default one for the current session. Using setDefaultCluster(NULL) removes the registered cluster, as does stopping that cluster.

Value

For the cluster creators, an object of class c("SOCKcluster", "cluster").

For the default cluster setter and getter, the registered default cluster or NULL if there is no such cluster.

Derived from the snow package.
**mcaffinity**

Get or Set CPU Affinity Mask of the Current Process

**Description**

mcaffinity retrieves or sets the CPU affinity mask of the current process, i.e., the set of CPUs the process is allowed to be run on. (CPU here means logical CPU which can be CPU, core or hyperthread unit.)

**Usage**

mcaffinity(affinity = NULL)

**Arguments**

affinity specification of the CPUs to lock this process to (numeric vector) or NULL if no change is requested

**Details**

mcaffinity can be used to obtain (affinity = NULL) or set the CPU affinity mask of the current process. The affinity mask is a list of integer CPU identifiers (starting from 1) that this process is allowed to run on. Not all systems provide user access to the process CPU affinity, in cases where no support is present at all mcaffinity() will return NULL. Some systems may take into account only the number of CPUs present in the mask.

Typically, it is legal to specify larger set than the number of logical CPUs (but at most as many as the OS can handle) and the system will return back the actually present set.

**Value**

NULL if CPU affinity is not supported by the system or an integer vector with the set of CPUs in the active affinity mask for this process (this may be different than affinity).

**Author(s)**

Simon Urbanek.

mcparallel
Low-level Functions for Management of Forked Processes

Description

These are low-level support functions for the forking approach. They are not available on Windows, and not exported from the namespace.

Usage

```r
children(select)
readChild(child)
readChildren(timeout = 0)
selectChildren(children = NULL, timeout = 0)
sendChildStdin(child, what)
sendMaster(what)
mckill(process, signal = 2L)
```

Arguments

- `select` if omitted, all active children are returned, otherwise `select` should be a list of processes and only those from the list that are active will be returned.
- `child` child process (object of the class "childProcess") or a process ID (pid). See also 'Details'.
- `timeout` timeout (in seconds, fractions supported) to wait for a response before giving up.
- `children` list of child processes or a single child process object or a vector of process IDs or NULL. If NULL behaves as if all currently known children were supplied.
- `what` For `sendChildStdin`: Character or raw vector. In the former case elements are collapsed using the newline character. (But no trailing newline is added at the end!)
  For `sendMaster`: Data to send to the master process. If what is not a raw vector, it will be serialized into a raw vector. Do NOT send an empty raw vector – that is reserved for internal use.
- `process` process (object of the class process) or a process ID (pid)
- `signal` integer: signal to send. Values of 2 (SIGINT), 9 (SIGKILL) and 15 (SIGTERM) are pretty much portable, but for maximal portability use `tools::SIGTERM` and so on.

Details

- `children` returns currently active children.
- `readChild` reads data (sent by `sendMaster`) from a given child process.
- `selectChildren` checks children for available data.
- `readChildren` checks all children for available data and reads from the first child that has available data.
sendChildStdin sends a string (or data) to one or more child's standard input. Note that if the master session was interactive, it will also be echoed on the standard output of the master process (unless disabled). The function is vector-compatible, so you can specify child as a list or a vector of process IDs.

sendMaster sends data from the child to the master process.

mckill sends a signal to a child process: it is equivalent to pskill in package tools.

Value

children returns a (possibly empty) list of objects of class "process", the process ID.
readChild and readChildren return a raw vector with a "pid" attribute if data were available, an integer vector of length one with the process ID if a child terminated or NULL if the child no longer exists (no children at all for readChildren).
selectChildren returns TRUE is the timeout was reached, FALSE if an error occurred (e.g., if the master process was interrupted) or an integer vector of process IDs with children that have data available, or NULL if there are no children.
sendChildStdin returns a vector of TRUE values (one for each member of child) or throws an error.
sendMaster returns TRUE or throws an error.
mckill returns TRUE.

Warning

This is a very low-level interface for expert use only: it not regarded as part of the R API and subject to change without notice.

sendMaster, readChild and sendChildStdin did not support long vectors prior to R 3.4.0 and so were limited to $2^{31} - 1$ bytes (and still are on 32-bit platforms).

mcfork, sendMaster, mcparallel

Examples

```r
## Not run:
p <- mcparallel(scan(n = 1, quiet = TRUE))
sendChildStdin(p, "17.4\n")
mccollect(p)[[1]]
## End(Not run)
```
**mcfork**  
Fork a Copy of the Current R Process

**Description**

These are low-level functions, not available on Windows, and not exported from the namespace.

*mcfork* creates a new child process as a copy of the current R process.

*mceexit* closes the current child process, informing the master process as necessary.

**Usage**

```r
mcfork(estranged = FALSE)
mcexit(exit.code = 0L, send = NULL)
```

**Arguments**

- `estranged` logical, if TRUE then the new process has no ties to the parent process, will not show in the list of children and will not be killed on exit.
- `exit.code` process exit code. By convention 0L signifies a clean exit, 1L an error.
- `send` if not NULL send this data before exiting (equivalent to using `sendMaster`).

**Details**

The *mcfork* function provides an interface to the *fork* system call. In addition it sets up a pipe between the master and child process that can be used to send data from the child process to the master (see `sendMaster`) and child’s ‘stdin’ is re-mapped to another pipe held by the master process (see `sendChildStdin`).

If you are not familiar with the *fork* system call, do not use this function directly as it leads to very complex inter-process interactions amongst the R processes involved.

In a nutshell, *fork* spawns a copy (child) of the current process, that can work in parallel to the master (parent) process. At the point of forking both processes share exactly the same state including the workspace, global options, loaded packages etc. Forking is relatively cheap in modern operating systems and no real copy of the used memory is created, instead both processes share the same memory and only modified parts are copied. This makes *mcfork* an ideal tool for parallel processing since there is no need to setup the parallel working environment, data and code is shared automatically from the start.

*mceexit* is to be run in the child process. It sends `send` to the master (unless NULL) and then shuts down the child process. The child can also be shut down by sending it the signal SIGUSR1, as is done by the unexported function `parallel:::rmChild`.

**Value**

*mcfork* returns an object of the class "childProcess" to the master and of class "masterProcess" to the child: both the classes inherit from class "process". If `estranged` is set to TRUE then the child process will be of the class "estrangedProcess" and cannot communicate with the master process nor will it show up on the list of children. These are lists with components `pid` (the process id of the other process) and a vector `fd` of the two file descriptor numbers for ends in the current process of the inter-process pipes.

*mceexit* never returns.
GUI/embedded environments

It is strongly discouraged to use mcfork and the higher-level functions which rely on it (e.g., mcparallel, mclapply and pvec) in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices. Some precautions have been taken to make this usable in R.app on macOS, but users of third-party front-ends should consult their documentation.

This can also apply to other connections (e.g., to an X server) created before forking, and to files opened by e.g. graphics devices.

Note that tcltk counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

Warning

This is a very low-level API for expert use only.

## This will work when run as an example, but not when pasted in.
p <- parallel:::mcfork()
if (inherits(p, "masterProcess")) {
  cat("I’m a child! ", Sys.getpid(), "\n")
  parallel:::mcexit("I was a child")
} else {
  cat("I’m the master\n")
  unserialize(parallel:::readChildren(1.5))
}
```

mclapply Parallel Versions of lapply and mapply using Forking

Description

mclapply is a parallelized version of lapply, it returns a list of the same length as X, each element of which is the result of applying FUN to the corresponding element of X.

It relies on forking and hence is not available on Windows unless mc.cores = 1.

mcmapply is a parallelized version of mapply, and mcMap corresponds to Map.
Usage

mclapply(X, FUN, ..., 
    mc.preschedule = TRUE, mc.set.seed = TRUE, 
    mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
    mc.cleanup = TRUE, mc.allow.recursive = TRUE, affinity.list = NULL)

mcmapply(FUN, ..., 
    MoreArgs = NULL, SIMPLIFY = TRUE, USE.NAMES = TRUE, 
    mc.preschedule = TRUE, mc.set.seed = TRUE, 
    mc.silent = FALSE, mc.cores = getOption("mc.cores", 2L), 
    mc.cleanup = TRUE, affinity.list = NULL)

mcMap(f, ...)

Arguments

X a vector (atomic or list) or an expressions vector. Other objects (including 
    classed objects) will be coerced by as.list.

FUN the function to be applied to (mclapply) each element of X or (mcmapply) in 
    parallel to ....

f the function to be applied in parallel to ....

... For mclapply, optional arguments to FUN. For mcmapply and mcMap, vector or 
    list inputs: see mapply.

MoreArgs, SIMPLIFY, USE.NAMES see mapply.

mc.preschedule if set to TRUE then the computation is first divided to (at most) as many jobs are 
    there are cores and then the jobs are started, each job possibly covering more 
    than one value. If set to FALSE then one job is forked for each value of X. The 
    former is better for short computations or large number of values in X, the latter 
    is better for jobs that have high variance of completion time and not too many 
    values of X compared to mc.cores.

mc.set.seed See mcparallel.

mc.silent if set to TRUE then all output on ‘stdout’ will be suppressed for all parallel 
    processes forked (‘stderr’ is not affected).

mc.cores The number of cores to use, i.e. at most how many child processes will be run 
    simultaneously. The option is initialized from environment variable MC_CORES 
    if set. Must be at least one, and parallelization requires at least two cores.

mc.cleanup if set to TRUE then all children that have been forked by this function will be 
    killed (by sending SIGTERM) before this function returns. Under normal cir- 
    cumstances mclapply waits for the children to deliver results, so this option 
    usually has only effect when mclapply is interrupted. If set to FALSE then child 
    processes are collected, but not forcefully terminated. As a special case this 
    argument can be set to the number of the signal that should be used to kill the 
    children instead of SIGTERM.

mc.allow.recursive Unless true, calling mclapply in a child process will use the child and not fork 
    again.

affinity.list a vector (atomic or list) containing the CPU affinity mask for each element of 
    X. The CPU affinity mask describes on which CPU (core or hyperthread unit) a 
    given item is allowed to run, see mcaffinity. To use this parameter preschedul- 
    ing has to be deactivated (mc.preschedule = FALSE).
**Details**

`mclapply` is a parallelized version of `lapply`, provided `mc.cores > 1`; for `mc.cores == 1` (and the `affinity.list` is `NULL`) it simply calls `lapply`.

By default (`mc.preschedule = TRUE`) the input `X` is split into as many parts as there are cores (currently the values are spread across the cores sequentially, i.e. first value to core 1, second to core 2, ... (core + 1)-th value to core 1 etc.) and then one process is forked to each core and the results are collected.

Without prescheduling, a separate job is forked for each value of `X`. To ensure that no more than `mc.cores` jobs are running at once, once that number has been forked the master process waits for a child to complete before the next fork.

Due to the parallel nature of the execution random numbers are not sequential (in the random number sequence) as they would be when using `lapply`. They are sequential for each forked process, but not all jobs as a whole. See `mcparallel` or the package’s vignette for ways to make the results reproducible with `mc.preschedule = TRUE`.

Note: the number of file descriptors (and processes) is usually limited by the operating system, so you may have trouble using more than 100 cores or so (see `ulimit -n` or similar in your OS documentation) unless you raise the limit of permissible open file descriptors (fork will fail with error "unable to create a pipe").

Prior to R 3.4.0 and on a 32-bit platform, the serialized result from each forked process is limited to $2^{31} - 1$ bytes. (Returning very large results via serialization is inefficient and should be avoided.)

`affinity.list` can be used to run elements of `X` on specific CPUs. This can be helpful, if elements of `X` have a high variance of completion time or if the hardware architecture is heterogeneous. It also enables the development of scheduling strategies for optimizing the overall runtime of parallel jobs. If `affinity.list` is set, the `mc.core` parameter is replaced with the number of CPU ids used in the affinity masks.

**Value**

For `mclapply`, a list of the same length as `X` and named by `X`.

For `mcapply`, a list, vector or array: see `mapply`.

For `McMap`, a list.

Each forked process runs its job inside `try(..., silent = TRUE)` so if errors occur they will be stored as class "try-error" objects in the return value and a warning will be given. Note that the job will typically involve more than one value of `X` and hence a "try-error" object will be returned for all the values involved in the failure, even if not all of them failed.

**Warning**

It is strongly discouraged to use these functions in GUI or embedded environments, because it leads to several processes sharing the same GUI which will likely cause chaos (and possibly crashes). Child processes should never use on-screen graphics devices.

Some precautions have been taken to make this usable in R.app on macOS, but users of third-party front-ends should consult their documentation.

Note that `tcltk` counts as a GUI for these purposes since Tcl runs an event loop. That event loop is inhibited in a child process but there could still be problems with Tk graphical connections.

mcparallel

Evaluate an R Expression Asynchronously in a Separate Process

Description

These functions are based on forking and so are not available on Windows.
mcparallel starts a parallel R process which evaluates the given expression.
mccollect collects results from one or more parallel processes.
Usage
mcparallel(expr, name, mc.set.seed = TRUE, silent = FALSE,
           mc.affinity = NULL, mc.interactive = FALSE,
           detached = FALSE)

mccollect(jobs, wait = TRUE, timeout = 0, intermediate = FALSE)

Arguments

expr expression to evaluate (do not use any on-screen devices or GUI elements in this code).
name an optional name (character vector of length one) that can be associated with the job.
mc.set.seed logical: see section ‘Random numbers’.
silent if set to TRUE then all output on stdout will be suppressed (stderr is not affected).
mc.affinity either a numeric vector specifying CPUs to restrict the child process to (1-based) or NULL to not modify the CPU affinity
mc.interactive logical, if TRUE or FALSE then the child process will be set as interactive or non-interactive respectively. If NA then the child process will inherit the interactive flag from the parent.
detached logical, if TRUE then the job is detached from the current session and cannot deliver any results back - it is used for the code side-effect only.
jobs list of jobs (or a single job) to collect results for. Alternatively jobs can also be an integer vector of process IDs. If omitted collect will wait for all currently existing children.
wait if set to FALSE it checks for any results that are available within timeout seconds from now, otherwise it waits for all specified jobs to finish.
timeout timeout (in seconds) to check for job results – applies only if wait is FALSE.
intermediate FALSE or a function which will be called while collect waits for results. The function will be called with one parameter which is the list of results received so far.

Details
mcparallel evaluates the expr expression in parallel to the current R process. Everything is shared read-only (or in fact copy-on-write) between the parallel process and the current process, i.e. no side-effects of the expression affect the main process. The result of the parallel execution can be collected using mccollect function.
mccollect function collects any available results from parallel jobs (or in fact any child process). If wait is TRUE then collect waits for all specified jobs to finish before returning a list containing the last reported result for each job. If wait is FALSE then mccollect merely checks for any results available at the moment and will not wait for jobs to finish. If jobs is specified, jobs not listed there will not be affected or acted upon.

Note: If expr uses low-level multicore functions such as sendMaster a single job can deliver results multiple times and it is the responsibility of the user to interpret them correctly. mccollect will return NULL for a terminating job that has sent its results already after which the job is no longer available.

Jobs are identified by process IDs (even when referred to as job objects), which are reused by the operating system. Detached jobs created by mcparallel can thus never be safely referred to
by their process IDs nor job objects. Non-detached jobs are guaranteed to exist until collected by mccollect, even if crashed or terminated by a signal. Once collected by mccollect, a job is regarded as detached, and thus must no longer be referred to by its process ID nor its job object. With \texttt{wait = TRUE}, all jobs passed to mccollect are collected. With \texttt{wait = FALSE}, the collected jobs are given as names of the result vector, and thus in subsequent calls to mccollect these jobs must be excluded. Job objects should be used in preference of process IDs whenever accepted by the API.

The \texttt{mc.affinity} parameter can be used to try to restrict the child process to specific CPUs. The availability and the extent of this feature is system-dependent (e.g., some systems will only consider the CPU count, others will ignore it completely).

**Value**

\texttt{mcparallel} returns an object of the class "parallelJob" which inherits from "childProcess" (see the ‘Value’ section of the help for \texttt{mcfork}). If argument \texttt{name} was supplied this will have an additional component \texttt{name}.

\texttt{mccollect} returns any results that are available in a list. The results will have the same order as the specified jobs. If there are multiple jobs and a job has a name it will be used to name the result, otherwise its process ID will be used. If none of the specified children are still running, it returns \texttt{NULL}.

**Random numbers**

If \texttt{mc.set.seed = FALSE}, the child process has the same initial random number generator (RNG) state as the current \texttt{R} session. If the RNG has been used (or \texttt{.Random.seed} was restored from a saved workspace), the child will start drawing random numbers at the same point as the current session. If the RNG has not yet been used, the child will set a seed based on the time and process ID when it first uses the RNG: this is pretty much guaranteed to give a different random-number stream from the current session and any other child process.

The behaviour with \texttt{mc.set.seed = TRUE} is different only if \texttt{RNGkind("L\'Ecuyer-CMRG")} has been selected. Then each time a child is forked it is given the next stream (see \texttt{nextRNGStream}). So if you select that generator, set a seed and call \texttt{mc.reset.stream} just before the first use of \texttt{mcparallel} the results of simulations will be reproducible provided the same tasks are given to the first, second, ...forked process.

**Note**

Prior to \texttt{R 3.4.0} and on a 32-bit platform, the serialized result from each forked process is limited to $2^{31} - 1$ bytes. (Returning very large results via serialization is inefficient and should be avoided.)

**Author(s)**

Simon Urbanek and R Core.

Derived from the \texttt{multicore} package formerly on CRAN. (but with different handling of the RNG stream).

**See Also**

\texttt{pvec, mclapply}
Examples

```r
p <- mcparallel(1:10)
q <- mcparallel(1:20)
# wait for both jobs to finish and collect all results
res <- mccollect(list(p, q))

## IGNORE_RDIFF_BEGIN
## reports process ids, so not reproducible
p <- mcparallel(1:10)
mccollect(p, wait = FALSE, 10) # will retrieve the result (since it's fast)
mccollect(p, wait = FALSE) # will signal the job as terminating
mccollect(p, wait = FALSE) # there is no longer such a job
## IGNORE_RDIFF_END

# a naive parallel lapply can be created using mcparallel alone:
jobs <- lapply(1:10, function(x) mcparallel(rnorm(x), name = x))
mccollect(jobs)
```

### pvec

**Parallelize a Vector Map Function using Forking**

#### Description

pvec parallelizes the execution of a function on vector elements by splitting the vector and submitting each part to one core. The function must be a vectorized map, i.e. it takes a vector input and creates a vector output of exactly the same length as the input which doesn’t depend on the partition of the vector.

It relies on forking and hence is not available on Windows unless `mc.cores = 1`.

#### Usage

```r
pvec(v, FUN, ..., mc.set.seed = TRUE, mc.silent = FALSE,
     mc.cores = getOption("mc.cores", 2L), mc.cleanup = TRUE)
```

#### Arguments

- `v` vector to operate on
- `FUN` function to call on each part of the vector
- `...` any further arguments passed to `FUN` after the vector
- `mc.set.seed` See `mcparallel`.
- `mc.silent` if set to `TRUE` then all output on `stdout` will be suppressed for all parallel processes forked (`stderr` is not affected).
- `mc.cores` The number of cores to use, i.e. at most how many child processes will be run simultaneously. Must be at least one, and at least two for parallel operation. The option is initialized from environment variable `MC_CORES` if set.
- `mc.cleanup` See the description of this argument in `mclapply`.
Details

pvec parallelizes FUN(x, ...) where FUN is a function that returns a vector of the same length as x. FUN must also be pure (i.e., without side-effects) since side-effects are not collected from the parallel processes. The vector is split into nearly identically sized subvectors on which FUN is run. Although it is in principle possible to use functions that are not necessarily maps, the interpretation would be case-specific as the splitting is in theory arbitrary (a warning is given in such cases).

The major difference between pvec and mclapply is that mclapply will run FUN on each element separately whereas pvec assumes that c(FUN(x[1]), FUN(x[2])) is equivalent to FUN(x[1:2]) and thus will split into as many calls to FUN as there are cores (or elements, if fewer), each handling a subset vector. This makes it more efficient than mclapply but requires the above assumption on FUN.

If mc.cores == 1 this evaluates FUN(v, ...) in the current process.

Value

The result of the computation – in a successful case it should be of the same length as v. If an error occurred or the function was not a map the result may be shorter or longer, and a warning is given.

Note

Due to the nature of the parallelization, error handling does not follow the usual rules since errors will be returned as strings and results from killed child processes will show up simply as non-existent data. Therefore it is the responsibility of the user to check the length of the result to make sure it is of the correct size. pvec raises a warning if that is the case since it does not know whether such an outcome is intentional or not.

See mcfork for the inadvisability of using this with GUI front-ends.

mcparallel, mclapply, parLapply, clusterMap.

Examples

```r
x <- pvec(1:1000, sqrt)
stopifnot(all(x == sqrt(1:1000)))
```

```
# One use is to convert date strings to unix time in large datasets
# as that is a relatively slow operation.
# So let's get some random dates first
# (A small test only with 2 cores: set options("mc.cores")
# and increase N for a larger-scale test.)
N <- 1e5
dates <- sprintf('%04d-%02d-%02d', as.integer(2000+runif(N)),
    as.integer(runif(N, 1, 12)), as.integer(runif(N, 1, 28)))

system.time(a <- as.POSIXct(dates))
```
# But specifying the format is faster
system.time(a <- as.POSIXct(dates, format = "%Y-%m-%d"))

# pvec ought to be faster, but system overhead can be high
system.time(b <- pvec(dates, as.POSIXct, format = "%Y-%m-%d"))
stopifnot(all(a == b))

# using mclapply for this would much slower because each value
# will require a separate call to as.POSIXct()
# as lapply(dates, as.POSIXct) does
system.time(c <- unlist(mclapply(dates, as.POSIXct, format = "%Y-%m-%d")))
stopifnot(all(a == c))

---

### RNGstreams

**Implementation of Pierre L’Ecuyer’s RngStreams**

**Description**

This is an R re-implementation of Pierre L’Ecuyer’s `RngStreams` multiple streams of pseudo-random numbers.

**Usage**

- `nextRNGStream(seed)`
- `nextRNGSubStream(seed)`
- `clusterSetRNGStream(cl = NULL, iseed)`
- `mc.reset.stream()`

**Arguments**

- `seed` An integer vector of length 7 as given by `.Random.seed` when the "L’Ecuyer-CMRG" RNG is in use. See `RNG` for the valid values.
- `cl` A cluster from this package or package `snow`, or (if `NULL`) the registered cluster.
- `iseed` An integer to be supplied to `set.seed`, or `NULL` not to set reproducible seeds.

**Details**

The ‘RngStream’ interface works with (potentially) multiple streams of pseudo-random numbers: this is particularly suitable for working with parallel computations since each task can be assigned a separate RNG stream.

This uses as its underlying generator `RNGkind("L 'Ecuyer-CMRG")`, of L’Ecuyer (1999), which has a seed vector of 6 (signed) integers and a period of around $2^{191}$. Each ‘stream’ is a subsequence of the period of length $2^{127}$ which is in turn divided into ‘substreams’ of length $2^{76}$.

The idea of L’Ecuyer et al (2002) is to use a separate stream for each of the parallel computations (which ensures that the random numbers generated never get into sync) and the parallel computations can themselves use substreams if required. The original interface stores the original seed of the first stream, the original seed of the current stream and the current seed: this could be implemented in R, but it is as easy to work by saving the relevant values of `.Random.seed`: see the examples.
clusterSetRNGStream selects the "L'Ecuyer-CMRG" RNG and then distributes streams to the members of a cluster, optionally setting the seed of the streams by set.seed(iseed) (otherwise they are set from the current seed of the master process: after selecting the L’Ecuyer generator). Calling mc.reset.stream() after setting the L’Ecuyer random number generator and seed makes runs from mcparallel(mc.set.seed = TRUE) reproducible. This is done internally in mclapply and pvec. (Note that it does not set the seed in the master process, so does not affect the fallback-to-serial versions of these functions.)

Value

For nextRNGStream and nextRNGSubStream, a value which can be assigned to .Random.seed.

Note

Interfaces to L’Ecuyer’s C code are available in CRAN packages rlecuyer and rstream.

Chapter 9

The splines package

---

**splines-package**  
*Regression Spline Functions and Classes*

**Description**

Regression spline functions and classes.

**Details**

This package provides functions for working with regression splines using the B-spline basis, `bs`, and the natural cubic spline basis, `ns`.

For a complete list of functions, use `library(help = "splines")`.

**Author(s)**

Douglas M. Bates &lt;bates@stat.wisc.edu&gt; and William N. Venables &lt;Bill.Venables@csiro.au&gt;

Maintainer: R Core Team &lt;R-core@r-project.org&gt;

---

**asVector**  
*Coerce an Object to a Vector*

**Description**

This is a generic function. Methods for this function coerce objects of given classes to vectors.

**Usage**

`asVector(object)`

**Arguments**

- `object`  
  An object.
Details

Methods for vector coercion in new classes must be created for the asVector generic instead of as.vector. The as.vector function is internal and not easily extended. Currently the only class with an asVector method is the xyVector class.

Value

a vector

Author(s)

Douglas Bates and Bill Venables

See Also

xyVector

Examples

require(stats)
ispl <- interpSpline( weight ~ height, women )
pred <- predict(ispl)
class(pred)
utils::str(pred)
asVector(pred)

Description

Create a monotone inverse of a monotone natural spline.

Usage

backSpline(object)

Arguments

object an object that inherits from class nbSpline or npolySpline. That is, the object must represent a natural interpolation spline but it can be either in the B-spline representation or the piecewise polynomial one. The spline is checked to see if it represents a monotone function.

Value

An object of class polySpline that contains the piecewise polynomial representation of a function that has the appropriate values and derivatives at the knot positions to be an inverse of the spline represented by object. Technically this object is not a spline because the second derivative is not constrained to be continuous at the knot positions. However, it is often a much better approximation to the inverse than fitting an interpolation spline to the y/x pairs.

require(graphics)
ispl <- interpSpline( women$height, women$weight )bspl <- backSpline( ispl )plot( bspl ) # plots over the range of the knotspoints( women$weight, women$height )

bs

B-Spline Basis for Polynomial Splines

Description

Generate the B-spline basis matrix for a polynomial spline.

Usage

bs(x, df = NULL, knots = NULL, degree = 3, intercept = FALSE,Boundary.knots = range(x))

Arguments

x the predictor variable. Missing values are allowed.
df degrees of freedom; one can specify df rather than knots; bs() then chooses df-degree (minus one if there is an intercept) knots at suitable quantiles of x (which will ignore missing values). The default, NULL, takes the number of inner knots as length(knots). If that is zero as per default, that corresponds to df = degree - intercept.knots the internal breakpoints that define the spline. The default is NULL, which results in a basis for ordinary polynomial regression. Typical values are the mean or median for one knot, quantiles for more knots. See also Boundary.knots.degree degree of the piecewise polynomial—default is 3 for cubic splines.intercept if TRUE, an intercept is included in the basis; default is FALSE.Boundary.knots boundary points at which to anchor the B-spline basis (default the range of the non-NA data). If both knots and Boundary.knots are supplied, the basis parameters do not depend on x. Data can extend beyond Boundary.knots.

Details

bs is based on the function splineDesign. It generates a basis matrix for representing the family of piecewise polynomials with the specified interior knots and degree, evaluated at the values of x. A primary use is in modeling formulas to directly specify a piecewise polynomial term in a model. When Boundary.knots are set inside range(x), bs() now uses a ‘pivot’ inside the respective boundary knot which is important for derivative evaluation. In R versions ≤ 3.2.2, the boundary knot itself had been used as pivot, which lead to somewhat wrong extrapolations.
interpSpline

Create an Interpolation Spline

Description

Create an interpolation spline, either from \texttt{x} and \texttt{y} vectors (default method), or from a \texttt{formula} / \texttt{data.frame} combination (formula method).

Usage

\begin{verbatim}
interpSpline(obj1, obj2, bSpline = FALSE, period = NULL,
            ord = 4L, na.action = na.fail, sparse = FALSE)
\end{verbatim}

Arguments

- \texttt{obj1} either a numeric vector of \texttt{x} values or a formula.
- \texttt{obj2} if \texttt{obj1} is numeric this should be a numeric vector of the same length. If \texttt{obj1} is a formula this can be an optional data frame in which to evaluate the names in the formula.
Generate a Basis Matrix for Natural Cubic Splines

**Description**

Generate the B-spline basis matrix for a natural cubic spline.

**Usage**

```r
s(x, df = NULL, knots = NULL, intercept = FALSE, Boundary.knots = range(x))
```
Arguments

**x**  
the predictor variable. Missing values are allowed.

**df**  
degrees of freedom. One can supply df rather than knots; ns() then chooses df - 1 - intercept knots at suitably chosen quantiles of x (which will ignore missing values). The default, df = NULL, sets the number of inner knots as length(knots).

**knots**  
breakpoints that define the spline. The default is no knots; together with the natural boundary conditions this results in a basis for linear regression on x. Typical values are the mean or median for one knot, quantiles for more knots. See also Boundary.knots.

**intercept**  
if TRUE, an intercept is included in the basis; default is FALSE.

**Boundary.knots**  
boundary points at which to impose the natural boundary conditions and anchor the B-spline basis (default the range of the data). If both knots and Boundary.knots are supplied, the basis parameters do not depend on x. Data can extend beyond Boundary.knots.

Details

ns is based on the function splineDesign. It generates a basis matrix for representing the family of piecewise-cubic splines with the specified sequence of interior knots, and the natural boundary conditions. These enforce the constraint that the function is linear beyond the boundary knots, which can either be supplied or default to the extremes of the data.

A primary use is in modeling formula to directly specify a natural spline term in a model: see the examples.

Value

A matrix of dimension length(x) * df where either df was supplied or if knots were supplied, df = length(knots) + 1 + intercept. Attributes are returned that correspond to the arguments to ns, and explicitly give the knots, Boundary.knots etc for use by predict.ns().

Examples

```r
require(stats); require(graphics)
ns(women$height, df = 5)
summary(fm1 <- lm(weight ~ ns(height, df = 5), data = women))
## To see what knots were selected
attr(terms(fm1), "predvars")
## example of safe prediction
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, length.out = 200)
```
periodicSpline

Create a Periodic Interpolation Spline

Description
Create a periodic interpolation spline, either from \( x \) and \( y \) vectors, or from a formula/data.frame combination.

Usage
periodicSpline(obj1, obj2, knots, period = 2*pi, ord = 4L)

Arguments
- **obj1**: either a numeric vector of \( x \) values or a formula.
- **obj2**: if \( obj1 \) is numeric this should be a numeric vector of the same length. If \( obj1 \) is a formula this can be an optional data frame in which to evaluate the names in the formula.
- **knots**: optional numeric vector of knot positions.
- **period**: positive numeric value giving the period for the periodic spline. Defaults to \( 2 \times \pi \).
- **ord**: integer giving the order of the spline, at least 2. Defaults to 4. See `splineOrder` for a definition of the order of a spline.

Value
An object that inherits from class `spline`. The object can be in the B-spline representation, in which case it will be a `pbSpline` object, or in the piecewise polynomial representation (a `ppolySpline` object).

Author(s)
Douglas Bates and Bill Venables

See Also
- `splineKnots`, `interpSpline`

Examples
```r
require(graphics); require(stats)
xx <- seq( -pi, pi, length.out = 16 )[-1]
yy <- sin( xx )
frm <- data.frame( xx, yy )
pispl <- periodicSpline( xx, yy, period = 2 * pi )
pispl
pispl2 <- periodicSpline( yy ~ xx, frm, period = 2 * pi )
stopifnot(all.equal(pispl, pispl2)) # pispl and pispl2 are the same
```
polySpline  

**Piecewise Polynomial Spline Representation**

**Description**

Create the piecewise polynomial representation of a spline object.

**Usage**

```r
polySpline(object, ...)  
as.polySpline(object, ...)
```

**Arguments**

- `object` An object that inherits from class `spline`.
- `...` Optional additional arguments. At present no additional arguments are used.

**Value**

An object that inherits from class `polySpline`. This is the piecewise polynomial representation of a univariate spline function. It is defined by a set of distinct numeric values called knots. The spline function is a polynomial function between each successive pair of knots. At each interior knot the polynomial segments on each side are constrained to have the same value of the function and some of its derivatives.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

`interpSpline`, `periodicSpline`, `splineKnots`, `splineOrder`

**Examples**

```r
require(graphics)  
ispl <- polySpline(interpSpline( weight ~ height, women, bSpline = TRUE))  
print( ispl )  # print the piecewise polynomial representation  
plot( ispl )  # plots over the range of the knots  
points( women$height, women$weight )
```
**predict.bs**  
*Evaluate a Spline Basis*

**Description**

Evaluate a predefined spline basis at given values.

**Usage**

```r
## S3 method for class 'bs'
predict(object, newx, ...)

## S3 method for class 'ns'
predict(object, newx, ...)
```

**Arguments**

- `object` the result of a call to `bs` or `ns` having attributes describing knots, degree, etc.
- `newx` the x values at which evaluations are required.
- `...` Optional additional arguments. At present no additional arguments are used.

**Value**

An object just like `object`, except evaluated at the new values of `x`.

These are methods for the generic function `predict` for objects inheriting from classes "bs" or "ns". See `predict` for the general behavior of this function.

**See Also**

`bs`, `ns`, `poly`.

**Examples**

```r
require(stats)
basis <- ns(women$height, df = 5)
newX <- seq(58, 72, length.out = 51)
# evaluate the basis at the new data
predict(basis, newX)
```

---

**predict.bSpline**  
*Evaluate a Spline at New Values of x*

**Description**

The `predict` methods for the classes that inherit from the virtual classes bSpline and polySpline are used to evaluate the spline or its derivatives. The `plot` method for a spline object first evaluates `predict` with the `x` argument missing, then plots the resulting `xyVector` with `type = "l"`. 
## Usage

### S3 method for class 'bSpline'

```r
predict(object, x, nseg = 50, deriv = 0, ...)
```

### S3 method for class 'nbSpline'

```r
predict(object, x, nseg = 50, deriv = 0, ...)
```

### S3 method for class 'pbSpline'

```r
predict(object, x, nseg = 50, deriv = 0, ...)
```

### S3 method for class 'npolySpline'

```r
predict(object, x, nseg = 50, deriv = 0, ...)
```

### S3 method for class 'ppolySpline'

```r
predict(object, x, nseg = 50, deriv = 0, ...)
```

## Arguments

- **object**: An object that inherits from the `bSpline` or the `polySpline` class.
- **x**: A numeric vector of *x* values at which to evaluate the spline. If this argument is missing a suitable set of *x* values is generated as a sequence of `nseg` segments spanning the range of the knots.
- **nseg**: A positive integer giving the number of segments in a set of equally-spaced *x* values spanning the range of the knots in `object`. This value is only used if `x` is missing.
- **deriv**: An integer between 0 and `splineOrder(object) - 1` specifying the derivative to evaluate.
- **...**: Further arguments passed to or from other methods.

## Value

An `xyVector` with components

- **x**: the supplied or inferred numeric vector of *x* values
- **y**: the value of the spline (or its `deriv`th derivative) at the *x* vector

## Author(s)

Douglas Bates and Bill Venables

## See Also

`xyVector`, `interpSpline`, `periodicSpline`

## Examples

```r
require(graphics); require(stats)
ispl <- interpSpline(weight ~ height, women)
par(mfrow = c(2, 2), las = 1)
plot(predict(ispl, nseg = 201), # plots over the range of the knots
     main = "Original data with interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
points(women$height, women$weight, col = 4)
plot(predict(ispl, nseg = 201, deriv = 1),
     main = "First derivative of interpolating spline", type = "l",
     xlab = "height", ylab = "weight")
plot(predict(ispl, nseg = 201, deriv = 2),
```
splineDesign

Design Matrix for B-splines

Description
Evaluate the design matrix for the B-splines defined by knots at the values in x.

Usage
splineDesign(knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)
spline.des (knots, x, ord = 4, derivs, outer.ok = FALSE, sparse = FALSE)

Arguments
knots  a numeric vector of knot positions (which will be sorted increasingly if needed).
x      a numeric vector of values at which to evaluate the B-spline functions or derivatives. Unless outer.ok is true, the values in x must be between the “inner” knots knots[ord] and knots[ length(knots) - (ord-1)].
ord    a positive integer giving the order of the spline function. This is the number of coefficients in each piecewise polynomial segment, thus a cubic spline has order 4. Defaults to 4.
derivs an integer vector with values between 0 and ord - 1, conceptually recycled to the length of x. The derivative of the given order is evaluated at the x positions. Defaults to zero (or a vector of zeroes of the same length as x).
outer.ok  logical indicating if x should be allowed outside the inner knots, see the x argument.
sparse   logical indicating if the result should inherit from class "sparseMatrix" (from package Matrix).

Value
A matrix with length(x) rows and length(knots) - ord columns. The i’th row of the matrix contains the coefficients of the B-splines (or the indicated derivative of the B-splines) defined by the knot vector and evaluated at the i’th value of x. Each B-spline is defined by a set of ord successive knots so the total number of B-splines is length(knots) - ord.

Note
The older spline.des function takes the same arguments but returns a list with several components including knots, ord, derivs, and design. The design component is the same as the value of the splineDesign function.
Author(s)
Douglas Bates and Bill Venables

Examples

```r
require(graphics)
splineDesign(knots = 1:10, x = 4:7)
splineDesign(knots = 1:10, x = 4:7, deriv = 1)
## visualize band structure
Matrix::drop0(zapsmall(6*splineDesign(knots = 1:40, x = 4:37, sparse = TRUE)))

knots <- c(1,1.8,3:5,6,5,7,8,1,9,2,10)  # 10 => 10-4 = 6 Basis splines
x <- seq(min(knots)-1, max(knots)+1, length.out = 501)
bb <- splineDesign(knots, x = x, outer.ok = TRUE)

plot(range(x), c(0,1), type = "n", xlab = "x", ylab = "",
     main = "B-splines - sum to 1 inside inner knots")
mtext(expression(B[j](x) " and " \sum(B[j](x), j == 1, 6)), adj = 0)
abline(v = knots, lty = 3, col = "light gray")
abline(v = knots[c(4,length(knots)-3)], lty = 3, col = "gray10")
lines(x, rowSums(bb), col = "gray", lwd = 2)
matlines(x, bb, ylim = c(0,1), lty = 1)
```

---

**splineKnots**

*Knot Vector from a Spline*

### Description

Return the knot vector corresponding to a spline object.

### Usage

```r
splineKnots(object)
```

### Arguments

- `object` an object that inherits from class "spline".

### Value

A non-decreasing numeric vector of knot positions.

### Author(s)

Douglas Bates and Bill Venables

### Examples

```r
ispl <- interpSpline( weight ~ height, women )
splineKnots( ispl )
```
**splineOrder**

*Determine the Order of a Spline*

**Description**

Return the order of a spline object.

**Usage**

`splineOrder(object)`

**Arguments**

- `object` An object that inherits from class "spline".

**Details**

The order of a spline is the number of coefficients in each piece of the piecewise polynomial representation. Thus a cubic spline has order 4.

**Value**

A positive integer.

**Author(s)**

Douglas Bates and Bill Venables

**See Also**

splineKnots, interpSpline, periodicSpline

**Examples**

`splineOrder( interpSpline( weight ~ height, women ) )`

---

**xyVector**

*Construct an xyVector Object*

**Description**

Create an object to represent a set of x-y pairs. The resulting object can be treated as a matrix or as a data frame or as a vector. When treated as a vector it reduces to the y component only.

The result of functions such as `predict.spline` is returned as an `xyVector` object so the x-values used to generate the y-positions are retained, say for purposes of generating plots.

**Usage**

`xyVector(x, y)`
Arguments

- \( x \) a numeric vector
- \( y \) a numeric vector of the same length as \( x \)

Value

An object of class \( \text{xyVector} \) with components

- \( x \) a numeric vector
- \( y \) a numeric vector of the same length as \( x \)

Author(s)

Douglas Bates and Bill Venables

Examples

```r
require(stats); require(graphics)
ispl <- interpSpline( weight ~ height, women )
weights <- predict( ispl, seq( 55, 75, length.out = 51 ))
class( weights )
plot( weights, type = "l", xlab = "height", ylab = "weight" )
points( women$height, women$weight )
weights
```
Chapter 10

The stats package

stats-package  The R Stats Package

Description

R statistical functions

Details

This package contains functions for statistical calculations and random number generation. For a complete list of functions, use library(help = "stats").

Maintainer: R Core Team <R-core@r-project.org>

.checkMFClasses  Functions to Check the Type of Variables passed to Model Frames

Description

.checkMFClasses checks if the variables used in a predict method agree in type with those used for fitting.
.MFclass categorizes variables for this purpose.

Usage

.checkMFClasses(cl, m, ordNotOK = FALSE)
.MFclass(x)
.getXlevels(Terms, m)
acf

Auto- and Cross-Covariance and -Correlation Function Estimation

Description

The function acf computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function pacf is the function used for the partial autocorrelations. Function ccf computes the cross-correlation or cross-covariance of two univariate series.

Usage

acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)

tpacf(x, lag.max, plot, na.action, ...)

## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail, ...)

ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)

## S3 method for class 'acf'
x[i, j]
acf

Arguments

x, y  
a univariate or multivariate (not ccf) numeric time series object or a numeric vector or matrix, or an "acf" object.

lag.max  
maximum lag at which to calculate the acf. Default is $10 \log_{10}(N/m)$ where $N$ is the number of observations and $m$ the number of series. Will be automatically limited to one less than the number of observations in the series.

type  
character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial". Will be partially matched.

plot  
logical. If TRUE (the default) the acf is plotted.

na.action  
function to be called to handle missing values. na.pass can be used.

demean  
logical. Should the covariances be about the sample means?

...  
further arguments to be passed to plot.acf.

i  
a set of lags (time differences) to retain.

j  
a set of series (names or numbers) to retain.

Details

For type = "correlation" and "covariance", the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the na.action function passes through missing values (as na.pass does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to lag.max.

The generic function plot has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are print and subsetting methods for objects of class "acf".

Value

An object of class "acf", which is a list with the following elements:

lag  
A three dimensional array containing the lags at which the acf is estimated.

acf  
An array with the same dimensions as lag containing the estimated acf.

type  
The type of correlation (same as the type argument).

n.used  
The number of observations in the time series.

series  
The name of the series x.

snames  
The series names for a multivariate time series.

The lag k value returned by ccf(x, y) estimates the correlation between x[t+k] and y[t]. The result is returned invisibly if plot is TRUE.

plot.acf, ARMAacf for the exact autocorrelations of a given ARMA process.

Examples

```r
require(graphics)

## Examples from Venables & Ripley
acf(lh)
acf(lh, type = "covariance")
pacf(lh)

acf(ldeaths)
acf(ldeaths, ci.type = "ma")
acf(ts.union(mdeaths, fdeaths))
ccf(mdeaths, fdeaths, ylab = "cross-correlation")
# (just the cross-correlations)

presidents # contains missing values
acf(presidents, na.action = na.pass)
pacf(presidents, na.action = na.pass)
```

acf2AR

Compute an AR Process Exactly Fitting an ACF

Description

Compute an AR process exactly fitting an autocorrelation function.

Usage

```r
acf2AR(acf)
```

Arguments

*acf* 
An autocorrelation or autocovariance sequence.

Value

A matrix, with one row for the computed AR(p) coefficients for 1 <= p <= length(acf).

See Also

ARMAacf, ar.yw which does this from an empirical ACF.
Examples

```r
(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)
```

---

**add1**

*Add or Drop All Possible Single Terms to a Model*

**Description**

Compute all the single terms in the `scope` argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

**Usage**

```r
add1(object, scope, ...)  
# Default S3 method:  
add1(object, scope, scale = 0, test = c("none", "Chisq"),  
     k = 2, trace = FALSE, ...)

# S3 method for class 'lm'  
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
     x = NULL, k = 2, ...)

# S3 method for class 'glm'  
add1(object, scope, scale = 0,  
     test = c("none", "Rao", "LRT", "Chisq", "F"),  
     x = NULL, k = 2, ...)

drop1(object, scope, ...)  
# Default S3 method:  
drop1(object, scope, scale = 0, test = c("none", "Chisq"),  
     k = 2, trace = FALSE, ...)

# S3 method for class 'lm'  
drop1(object, scope, scale = 0, all.cols = TRUE,  
     test = c("none", "Chisq", "F"), k = 2, ...)

# S3 method for class 'glm'  
drop1(object, scope, scale = 0,  
     test = c("none", "Rao", "LRT", "Chisq", "F"),  
     k = 2, ...)
```

**Arguments**

- `object` a fitted model object.
- `scope` a formula giving the terms to be considered for adding or dropping.
- `scale` an estimate of the residual mean square to be used in computing $C_p$. Ignored if 0 or NULL.
should the results include a test statistic relative to the original model? The F test is only appropriate for \texttt{lm} and \texttt{aov} models or perhaps for \texttt{glm} fits with estimated dispersion. The $\chi^2$ test can be an exact test (\texttt{lm} models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method. For \texttt{glm} fits, you can also choose "LRT" and "Rao" for likelihood ratio tests and Rao’s efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution). Values can be abbreviated.

- **k**
  - the penalty constant in AIC / $C_p$.

- **trace**
  - if TRUE, print out progress reports.

- **x**
  - a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if \texttt{add1} is to be called repeatedly. **Warning:** no checks are done on its validity.

- **all.cols**
  - (Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.

- **...**
  - further arguments passed to or from other methods.

### Details

For \texttt{drop1} methods, a missing scope is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a scope formula . means ‘what is already there’.

The methods for \texttt{lm} and \texttt{glm} are more efficient in that they do not recompute the model matrix and call the fit methods directly.

The default output table gives AIC, defined as minus twice log likelihood plus 2$p$ where $p$ is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows’ $C_p$, $RSS/scale + 2p - n$. Where $C_p$ is used, the column is labelled as $C_p$ rather than AIC.

The F tests for the \texttt{glm} methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of \texttt{anova.glm}.

### Value

An object of class "anova" summarizing the differences in fit between the models.

### Warning

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if \texttt{na.action = na.omit}, but this may give biased results. Only use these functions with data containing missing values with great care.

The default methods make calls to the function \texttt{nobs} to check that the number of observations involved in the fitting process remained unchanged.
Note

These are not fully equivalent to the functions in S. There is no keep argument, and the methods
used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ $C_p$ and Akaike’s AIC are used, not those of the authors of
the models chapter of S.

Author(s)

The design was inspired by the S functions of the same names described in Chambers (1992).

addmargins

Puts Arbitrary Margins on Multidimensional Tables or Arrays

Description

For a given table one can specify which of the classifying factors to expand by one or more levels to
hold margins to be calculated. One may for example form sums and means over the first dimension
and medians over the second. The resulting table will then have two extra levels for the first dimen-
sion and one extra level for the second. The default is to sum over all margins in the table. Other
possibilities may give results that depend on the order in which the margins are computed. This is
flagged in the printed output from the function.

Usage

addmargins(A, margin = seq_along(dim(A)), FUN = sum, quiet = FALSE)
Arguments

A  table or array. The function uses the presence of the "dim" and "dimnames" attributes of A.

margin  vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in margin.

FUN  list of the same length as margin, each element of the list being either a function or a list of functions. Names of the list elements will appear as levels in dimnames of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table.

quiet  logical which suppresses the message telling the order in which the margins were computed.

Details

If the functions used to form margins are not commutative the result depends on the order in which margins are computed. Annotation of margins is done via naming the FUN list.

Value

A table or array with the same number of dimensions as A, but with extra levels of the dimensions mentioned in margin. The number of levels added to each dimension is the length of the entries in FUN. A message with the order of computation of margins is printed.

print(tx, zero.print = ".")

aggregate

Compute Summary Statistics of Data Subsets

Description
Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.

Usage
aggregate(x, 

## Default S3 method:
aggregate(x, 

## S3 method for class 'data.frame'
aggregate(x, by, FUN, ..., simplify = TRUE, drop = TRUE)

## S3 method for class 'formula'
aggregate(formula, data, FUN, ..., subset, na.action = na.omit)

## S3 method for class 'ts'
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1,
ts.eps = getOption("ts.eps"), ...)

Arguments

x
an R object.

by
a list of grouping elements, each as long as the variables in the data frame x. The elements are coerced to factors before use.

FUN
a function to compute the summary statistics which can be applied to all data subsets.

simplify
a logical indicating whether results should be simplified to a vector or matrix if possible.
aggregate

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>

</tr>
</tbody>
</table>

Details

aggregate is a generic function with methods for data frames and time series.

The default method, aggregate.default, uses the time series method if x is a time series, and otherwise coerces x to a data frame and calls the data frame method.

aggregate.data.frame is the data frame method. If x is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in x is split into subsets of cases (rows) of identical combinations of the components of by, and FUN is applied to each such subset with further arguments in ... passed to it. The result is reformatted into a data frame containing the variables in by and x. The ones arising from by contain the unique combinations of grouping values used for determining the subsets, and the ones arising from x the corresponding summaries for the subset of the respective variables in x. If simplify is true, summaries are simplified to vectors or matrices if they have a common length of one or greater than one, respectively; otherwise, lists of summary results according to subsets are obtained. Rows with missing values in any of the by variables will be omitted from the result. (Note that versions of R prior to 2.11.0 required FUN to be a scalar function.)

aggregate.formula is a standard formula interface to aggregate.data.frame.

aggregate.ts is the time series method, and requires FUN to be a scalar function. If x is not a time series, it is coerced to one. Then, the variables in x are split into appropriate blocks of length frequency(x) / nfrequency, and FUN is applied to each such block, with further (named) arguments in ... passed to it. The result returned is a time series with frequency nfrequency holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

FUN is passed to match.fun, and hence it can be a function or a symbol or character string naming a function.

Value

For the time series method, a time series of class "ts" or class c("mts", "ts").
aggregate

For the data frame method, a data frame with columns corresponding to the grouping variables in by followed by aggregated columns from x. If the by has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named `Group.i` for `by[[i]]`.

Author(s)

Kurt Hornik, with contributions by Arni Magnusson.

Examples

## Compute the averages for the variables in ‘state.x77’, grouped
## according to the region (Northeast, South, North Central, West) that
## each state belongs to.
aggregate(state.x77, list(Region = state.region), mean)

## Compute the averages according to region and the occurrence of more
## than 130 days of frost.
aggregate(state.x77,
  list(Region = state.region,
       Cold = state.x77[, "Frost"] > 130),
  mean)
## (Note that no state in ‘South’ is THAT cold.)

## example with character variables and NAs
testDF <- data.frame(v1 = c(1,3,5,7,8,3,5,NA,4,5,7,9),
                     v2 = c(11,33,55,77,88,33,55,NA,44,55,77,99))
by1 <- c("red", "blue", 1, 2, NA, "big", 1, 2, "red", 1, NA, 12)
by2 <- c("wet", "dry", 99, 95, NA, "damp", 95, 99, "red", 99, NA, NA)
aggregate(x = testDF, by = list(by1, by2), FUN = "mean")

# and if you want to treat NAs as a group
fby1 <- factor(by1, exclude = "")
fby2 <- factor(by2, exclude = "")
aggregate(x = testDF, by = list(fby1, fby2), FUN = "mean")

## Formulas, one ~ one, one ~ many, many ~ one, and many ~ many:
aggregate(weight ~ feed, data = chickwts, mean)
aggregate(breaks ~ wool + tension, data = warpbreaks, mean)
aggregate(cbind(Ozone, Temp) ~ Month, data = airquality, mean)
aggregate(cbind(ncases, ncontrols) ~ alcgp + tobgp, data = esoph, sum)

## Dot notation:
aggregate(. ~ Species, data = iris, mean)
aggregate(len ~ ., data = ToothGrowth, mean)
### Often followed by `xtabs()`:

```r
ag <- aggregate(len ~ ., data = ToothGrowth, mean)
xtabs(len ~ ., data = ag)
```

### Compute the average annual approval ratings for American presidents.

```r
aggregate(presidents, nfrequency = 1, FUN = mean)
```

```r
aggregate(presidents, nfrequency = 1,
  FUN = weighted.mean, w = c(1, 1, 0.5, 1))
```

### AIC

**Akaıke’s An Information Criterion**

**Description**

Generic function calculating Akaıke’s ‘An Information Criterion’ for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula 
\[-2 \log \text{-likelihood} + k n_{\text{par}},\]
where \( n_{\text{par}} \) represents the number of parameters in the fitted model, and \( k = 2 \) for the usual AIC, or \( k = \log(n) \) (\( n \) being the number of observations) for the so-called BIC or SBC (Schwarz’s Bayesian criterion).

**Usage**

```r
AIC(object, ..., k = 2)
BIC(object, ...)
```

**Arguments**

- `object`: a fitted model object for which there exists a `logLik` method to extract the corresponding log-likelihood, or an object inheriting from class `logLik`.
- `...`: optionally more fitted model objects.
- `k`: numeric, the penalty per parameter to be used; the default \( k = 2 \) is the classical AIC.

**Details**

When comparing models fitted by maximum likelihood to the same data, the smaller the AIC or BIC, the better the fit.

The theory of AIC requires that the log-likelihood has been maximized: whereas AIC can be computed for models not fitted by maximum likelihood, their AIC values should not be compared.

Examples of models not ‘fitted to the same data’ are where the response is transformed (accelerated-life models are fitted to log-times) and where contingency tables have been used to summarize data.

These are generic functions (with S4 generics defined in package `stats4`): however methods should be defined for the log-likelihood function `logLik` rather than these functions: the action of their default methods is to call `logLik` on all the supplied objects and assemble the results. Note that in several common cases `logLik` does not return the value at the MLE; see its help page.

The log-likelihood and hence the AIC/BIC is only defined up to an additive constant. Different constants have conventionally been used for different purposes and so `extractAIC` and AIC may
give different values (and do for models of class "lm": see the help for \texttt{extractAIC}). Particular care is needed when comparing fits of different classes (with, for example, a comparison of a Poisson and gamma GLM being meaningless since one has a discrete response, the other continuous).

\texttt{BIC} is defined as \texttt{AIC(object, ..., k = log(nobs(object))}). This needs the number of observations to be known: the default method looks first for a "\texttt{nobs}" attribute on the return value from the \texttt{logLik} method, then tries the \texttt{nobs} generic, and if neither succeed returns BIC as \texttt{NA}.

**Value**

If just one object is provided, a numeric value with the corresponding AIC (or BIC, or \ldots, depending on \texttt{k}).

If multiple objects are provided, a \texttt{data.frame} with rows corresponding to the objects and columns representing the number of parameters in the model (\texttt{df}) and the AIC or BIC.

**Author(s)**

Originally by José Pinheiro and Douglas Bates, more recent revisions by R-core.

**References**

**See Also**

\texttt{extractAIC, logLik, nobs}.

**Examples**

```r
lm1 <- lm(Fertility ~ ., data = swiss)
AIC(lm1)
stopifnot(all.equal(AIC(lm1),

AIC(logLik(lm1))))
BIC(lm1)

lm2 <- update(lm1, . ~ . - Examination)
AIC(lm1, lm2)
BIC(lm1, lm2)
```

**Description**

Find aliases (linearly dependent terms) in a linear model specified by a formula.
Usage

alias(object, ...)  
## S3 method for class 'formula'
alias(object, data, ...)

## S3 method for class 'lm'
alias(object, complete = TRUE, partial = FALSE, partial.pattern = FALSE, ...)

Arguments

object A fitted model object, for example from lm or aov, or a formula for alias.formula.
data Optionally, a data frame to search for the objects in the formula.
complete Should information on complete aliasing be included?
partial Should information on partial aliasing be included?
partial.pattern Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients.
...
... further arguments passed to or from other methods.

Details

Although the main method is for class "lm", alias is most useful for experimental designs and so is used with fits from aov. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Some parts of the "lm" method require recommended package MASS to be installed.

Value

A list (of class "listof") containing components

Model Description of the model; usually the formula.
Complete A matrix with columns corresponding to effects that are linearly dependent on the rows.
Partial The correlations of the estimable effects, with a zero diagonal. An object of class "mtable" which has its own print method.

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).
References

Examples

```r
op <- options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op) # reset
```

anova

Anova Tables

Description

Compute analysis of variance (or deviance) tables for one or more fitted model objects.

Usage

```r
anova(object, ...)
```

Arguments

- `object`:
  - an object containing the results returned by a model fitting function (e.g., `lm` or `glm`).
- `...`:
  - additional objects of the same type.

Value

This (generic) function returns an object of class `anova`. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.

When given a sequence of objects, `anova` tests the models against one another in the order specified.

The print method for `anova` objects prints tables in a ‘pretty’ form.

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used.

References

See Also

coefficients, effects, fitted.values, residuals, summary, drop1, add1.
Compute an analysis of deviance table for one or more generalized linear model fits.

Arguments

object, ... objects of class glm, typically the result of a call to glm, or a list of objects for the "glmlist" method.
dispersion the dispersion parameter for the fitting family. By default it is obtained from the object(s).
test a character string, (partially) matching one of "Chisq", "LRT", "Rao", "F" or "Cp". See stat.anova.

Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., gaussian, quasibinomial and quasipoisson fits) the F test is most appropriate. Mallows' $C_p$ statistic is the residual deviance plus twice the estimate of $\sigma^2$ times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known). You can also choose "LRT" and "Rao" for likelihood ratio tests and Rao's efficient score test. The former is synonymous with "Chisq" (although both have an asymptotic chi-square distribution).

The dispersion estimate will be taken from the largest model, using the value returned by summary.glm. As this will in most cases use a Chisquared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of na.action = na.omit is used, and anova will detect this with an error.

anova.lm

ANOVA for Linear Model Fits

Description
Compute an analysis of variance table for one or more linear model fits.

Usage
## S3 method for class 'lm'
anova(object, ...)

## S3 method for class 'lmlist'
anova(object, ..., scale = 0, test = "F")

Arguments
object, ... objects of class lm, usually, a result of a call to lm.
test a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or NULL for no test.
scale numeric. An estimate of the noise variance $\sigma^2$. If zero this will be estimated from the largest model considered.

Details
Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.
The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.
If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If `scale` is specified chi-squared tests can be used. Mallows’ $C_p$ statistic is the residual sum of squares plus twice the estimate of $\sigma^2$ times the residual degrees of freedom.

**Value**

An object of class "anova" inheriting from class "data.frame".

**Warning**

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R’s default of `na.action = na.omit` is used, and `anova.lmlist` will detect this with an error.

## sequential table
fit <- lm(sr ~ ., data = LifeCycleSavings)
anova(fit)

## same effect via separate models
fit0 <- lm(sr ~ 1, data = LifeCycleSavings)
fit1 <- update(fit0, . ~ . + pop15)
fit2 <- update(fit1, . ~ . + pop75)
fit3 <- update(fit2, . ~ . + dpi)
fit4 <- update(fit3, . ~ . + ddpi)
anova(fit0, fit1, fit2, fit3, fit4, test = "F")
anova(fit4, fit2, fit0, test = "F") # unconventional order
```
anova.mlm

Comparisons between Multivariate Linear Models

Description

Compute a (generalized) analysis of variance table for one or more multivariate linear models.

Usage

```r
## S3 method for class 'mlm'
anova(object, ..., 
    test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy", "Spherical"),
    Sigma = diag(nrow = p), T = Thin.row(proj(M) - proj(X)),
    M = diag(nrow = p), X = ~0,
    idata = data.frame(index = seq_len(p)), tol = 1e-7)
```

Arguments

- `object`: an object of class "mlm".
- `...`: further objects of class "mlm".
- `test`: choice of test statistic (see below). Can be abbreviated.
- `Sigma`: (only relevant if `test == "Spherical"`). Covariance matrix assumed proportional to `Sigma`.
- `T`: transformation matrix. By default computed from `M` and `X`.
- `M`: formula or matrix describing the outer projection (see below).
- `X`: formula or matrix describing the inner projection (see below).
- `idata`: data frame describing intra-block design.
- `tol`: tolerance to be used in deciding if the residuals are rank-deficient: see `qr`.

Details

The `anova.mlm` method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks’ statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See `summary.manova` for further details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using `Sigma`). Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted \( F \) tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix \( T \) can be given directly or specified as the difference between two projections onto the spaces spanned by \( M \) and \( X \), which in turn can be given as matrices or as model formulas with respect to `idata` (the tests will be invariant to parametrization of the quotient space \( M/X \)).

As with `anova.lm`, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.
Contrary to other anova methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

Value

An object of class "anova" inheriting from class "data.frame"

Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

### Traditional tests of intrasubj. contrasts
## Using MANOVA techniques on contrasts:
anova(mlmfit, mlmfit0, X = ~1)

## Assuming sphericity
anova(mlmfit, mlmfit0, X = ~1, test = "Spherical")

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0, 4, 8)),
                      noise = gl(2, 3, 6, labels = c("A", "P"))
anova(mlmfit, mlmfit0, X = ~ deg + noise,
      idata = idata, test = "Spherical")
anova(mlmfit, mlmfit0, M =~ deg + noise, X =~ noise,
      idata = idata, test = "Spherical")
anova(mlmfit, mlmfit0, M =~ deg + noise, X =~ deg,
      idata = idata, test = "Spherical")

f <- factor(rep(1:2, 5)) # bogus, just for illustration
mlmfit2 <- update(mlmfit, ~f)
anova(mlmfit2, mlmfit, mlmfit0, X = ~1, test = "Spherical")
anova(mlmfit2, X =~1, test = "Spherical")
# one-model form, eqiv. to previous

### There seems to be a strong interaction in these data
plot(colMeans(reacttime))
```
<ansari.test>

### Ansari-Bradley Test

**Description**

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

**Usage**

```r
ansari.test(x, y, 
    alternative = c("two.sided", "less", "greater"),
    exact = NULL, conf.int = FALSE, conf.level = 0.95,
    ...) 
## S3 method for class 'formula'
ansari.test(formula, data, subset, na.action, ...)
```

**Arguments**

- `x`: numeric vector of data values.
- `y`: numeric vector of data values.
- `alternative`: indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `exact`: a logical indicating whether an exact p-value should be computed.
- `conf.int`: a logical, indicating whether a confidence interval should be computed.
- `conf.level`: confidence level of the interval.
- `formula`: a formula of the form `lhs ~ rhs` where `lhs` is a numeric variable giving the data values and `rhs` a factor with two levels giving the corresponding groups.
- `data`: an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- `subset`: an optional vector specifying a subset of observations to be used.
- `na.action`: a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.
- `...`: further arguments to be passed to or from methods.

**Details**

Suppose that `x` and `y` are independent samples from distributions with densities \( f((t - m)/s)/s \) and \( f(t - m) \), respectively, where \( m \) is an unknown nuisance parameter and \( s \), the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that \( s = 1 \), the two-sided alternative being that \( s \neq 1 \) (the distributions differ only in variance), and the one-sided alternatives being \( s > 1 \) (the distribution underlying \( x \) has a larger variance, "greater") or \( s < 1 \) ("less").
By default (if exact is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for $s$ are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

Value

A list with class "htest" containing the following components:

- statistic: the value of the Ansari-Bradley test statistic.
- p.value: the p-value of the test.
- null.value: the ratio of scales $s$ under the null, 1.
- alternative: a character string describing the alternative hypothesis.
- method: the string "Ansari-Bradley test".
- data.name: a character string giving the names of the data.
- conf.int: a confidence interval for the scale parameter. (Only present if argument conf.int = TRUE.)
- estimate: an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)

Note

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that $s$ is the ratio of scales and hence $s^2$ is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for $s$ in the Ansari-Bradley test but for $s^2$ in the F test.

ansari.test(rnorm(10), rnorm(10, 0, 2), conf.int = TRUE)

## try more points - failed in 2.4.1
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)

---

aov

Fit an Analysis of Variance Model

Description

Fit an analysis of variance model by a call to lm for each stratum.

Usage

aov(formula, data = NULL, projections = FALSE, qr = TRUE, contrasts = NULL, ...)

Arguments

formula A formula specifying the model.
data A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.
projections Logical flag: should the projections be returned?
qr Logical flag: should the QR decomposition be returned?
contrasts A list of contrasts to be used for some of the factors in the formula. These are not used for any Error term, and supplying contrasts for factors only in the Error term will give a warning.
...

Arguments to be passed to lm, such as subset or na.action. See ‘Details’ about weights.

Details

This provides a wrapper to lm for fitting linear models to balanced or unbalanced experimental designs.

The main difference from lm is in the way print, summary and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single Error term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a weights argument, but should not be used with an Error term, and are incompletely supported (e.g., not by model.tables).
Value

An object of class c("aov", "lm") or for multiple responses of class c("maov", "aov", "mlm", "lm") or for multiple error strata of class c("aovlist", "listof"). There are print and summary methods available for these.

Note

aov is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use lme in package nlme.

Balance can be checked with the replications function.

The default ‘contrasts’ in R are not orthogonal contrasts, and aov and its helper functions will work better with such contrasts: see the examples for how to select these.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).

coefficients(npk.aov)

### to show the effects of re-ordering terms contrast the two fits

aov(yield ~ block + N * P + K, npk)
aov(terms(yield ~ block + N * P + K, keep.order = TRUE), npk)

### as a test, not particularly sensible statistically

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
npk.aovE
summary(npk.aovE)
options(op) # reset to previous
Interpolation Functions

Description

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.

Usage

\[
\text{approx} \quad (x, y = \text{NULL}, \text{xout}, \text{method} = \text{"linear"}, n = 50, \\
yleft, \text{yright}, \text{rule} = 1, f = 0, \text{ties} = \text{mean})
\]

\[
\text{approxfun}(x, y = \text{NULL}, \quad \text{method} = \text{"linear"}, \\
yleft, \text{yright}, \text{rule} = 1, f = 0, \text{ties} = \text{mean})
\]

Arguments

- **x**, **y**: numeric vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see `xy.coords`.
- **xout**: an optional set of numeric values specifying where interpolation is to take place.
- **method**: specifies the interpolation method to be used. Choices are "linear" or "constant".
- **n**: If `xout` is not specified, interpolation takes place at `n` equally spaced points spanning the interval `[min(x), max(x)]`.
- **yleft**: the value to be returned when input `x` values are less than `min(x)`. The default is defined by the value of `rule` given below.
- **yright**: the value to be returned when input `x` values are greater than `max(x)`. The default is defined by the value of `rule` given below.
- **rule**: an integer (of length 1 or 2) describing how interpolation is to take place outside the interval `[min(x), max(x)]`. If `rule` is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used. Use, e.g., `rule = 2:1`, if the left and right side extrapolation should differ.
- **f**: for `method = "constant"` a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If `y0` and `y1` are the values to the left and right of the point then the value is `y0` if `f == 0`, `y1` if `f == 1`, and `y0*(1-f)+y1*f` for intermediate values. In this way the result is right-continuous for `f == 0` and left-continuous for `f == 1`, even for non-finite `y` values.
- **ties**: handling of tied `x` values. Either a function with a single vector argument returning a single number result or the string "ordered"; note that the latter is the fastest for large `length(x)`.

Details

The inputs can contain missing values which are deleted, so at least two complete `(x, y)` pairs are required (for `method = "linear"`, one otherwise). If there are duplicated (tied) `x` values and `ties` is a function it is applied to the `y` values for each distinct `x` value. Useful functions in this context include `mean`, `min`, and `max`. If `ties = "ordered"` the `x` values are assumed to be already
ordered. The first y value will be used for interpolation to the left and the last one for interpolation to the right.

Value

approx returns a list with components x and y, containing n coordinates which interpolate the given data points according to the method (and rule) desired.

The function approxfun returns a function performing (linear or constant) interpolation of the given data points. For a given set of x values, this function will return the corresponding interpolated values. It uses data stored in its environment when it was created, the details of which are subject to change.

Warning

The value returned by approxfun contains references to the code in the current version of R: it is not intended to be saved and loaded into a different R session. This is safer for R >= 3.0.0.

References

See Also

spline and splinefun for spline interpolation.

Examples

```r
require(graphics)
x <- 1:10
y <- rnorm(10)
par(mfrow = c(2,1))
plot(x, y, main = "approx(.) and approxfun(.)")
points(approx(x, y), col = 2, pch = "+")
points(approx(x, y, method = "constant"), col = 4, pch = "+")
f <- approxfun(x, y)
curve(f(x), 0, 11, col = "green2")
points(x, y)
is.function(fc <- approxfun(x, y, method = "const")) # TRUE
curve(fc(x), 0, 10, col = "darkblue", add = TRUE)
## different extrapolation on left and right side :
plot(approxfun(x, y, rule = 2:1), 0, 11,
     col = "tomato", add = TRUE, lty = 3, lwd = 2)

## Show treatment of 'ties' :
x <- c(2,2:4,4,5,5,7,7,7)
y <- c(1:6, 5:4, 3:1)
approx(x, y, xout = x)$y # warning
(ay <- approx(x, y, xout = x, ties = "ordered")$y)
stopifnot(ay == c(2,2,3,6,6,4,4,1,1,1))
approx(x, y, xout = x, ties = min)$y
approx(x, y, xout = x, ties = max)$y
```
Fit Autoregressive Models to Time Series

Description

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.

Usage

ar(x, aic = TRUE, order.max = NULL,  
    method = c("yule-walker", "burg", "ols", "mle", "yw"),  
    na.action, series, ...)

ar.burg(x, ...)  
## Default S3 method:  
ar.burg(x, aic = TRUE, order.max = NULL,  
    na.action = na.fail, demean = TRUE, series,  
    var.method = 1, ...)

## S3 method for class 'mts'  
ar.burg(x, aic = TRUE, order.max = NULL,  
    na.action = na.fail, demean = TRUE, series,  
    var.method = 1, ...)

ar.yw(x, ...)  
## Default S3 method:  
ar.yw(x, aic = TRUE, order.max = NULL,  
    na.action = na.fail, demean = TRUE, series, ...)

## S3 method for class 'mts'  
ar.yw(x, aic = TRUE, order.max = NULL,  
    na.action = na.fail, demean = TRUE, series, ...)

ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,  
    demean = TRUE, series, ...)

## S3 method for class 'ar'  
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)

Arguments

x a univariate or multivariate time series.

aic logical. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order order.max is fitted.

order.max maximum order (or order) of model to fit. Defaults to the smaller of \( N - 1 \) and \( 10 \log_{10}(N) \) where \( N \) is the number of non-missing observations except for method = "mle" where it is the minimum of this quantity and 12.
method character string specifying the method to fit the model. Must be one of the strings in the default argument (the first few characters are sufficient). Defaults to "yule-walker".

na.action function to be called to handle missing values. Currently, via na.action = na.pass, only Yule-Walker method can handle missing values which must be consistent within a time point: either all variables must be missing or none.

demean should a mean be estimated during fitting?

series names for the series. Defaults to deparse(substitute(x)).

var.method the method to estimate the innovations variance (see 'Details').

... additional arguments for specific methods.

object a fit from ar().

newdata data to which to apply the prediction.

n.ahead number of steps ahead at which to predict.

se.fit logical: return estimated standard errors of the prediction error?

Details

For definiteness, note that the AR coefficients have the sign in

\[ x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t \]

ar is just a wrapper for the functions ar.yw, ar.burg, ar.ols and ar.mle.

Order selection is done by AIC if aic is true. This is problematic, as of the methods here only ar.mle performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In ar.yw the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of x.

ar.burg allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that ar includes by default a constant in the model, by removing the overall mean of x before fitting the AR model, or (ar.mle) estimating a constant to subtract.

Value

For ar and its methods a list of class "ar" with the following elements:

order The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.
ar Estimated autoregression coefficients for the fitted model.
var.pred The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
x.mean The estimated mean of the series used in fitting and for use in prediction.
x.intercept (ar.ols only.) The intercept in the model for x - x.mean.
The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of -Inf.

The number of observations in the time series, including missing.

The number of non-missing observations in the time series.

The value of the order.max argument.

The estimate of the partial autocorrelation function up to lag order.max.

resid

residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.

The value of the method argument.

The name(s) of the time series.

The frequency of the time series.

The matched call.

(univariate case, order > 0.) The asymptotic-theory variance matrix of the coefficient estimates.

For predict.ar, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

Note

Only the univariate case of ar.mle is implemented.

Fitting by method="mle" to long series can be very slow.

If x contains missing values, see NA, also consider using arima(), possibly with method = "ML".

Author(s)

Martyn Plummer. Univariate case of ar.yw, ar.mle and C code for univariate case of ar.burg by B. D. Ripley.

Examples

```r
ar(lh)
ar(lh, method = "burg")
ar(lh, method = "ols")
ar(lh, FALSE, 4) # fit ar(4)
```

```r
(sunspot.ar <- ar(sunspot.year))
predict(sunspot.ar, n.ahead = 25)
## try the other methods too
ar(ts.union(BJsales, BJsales.lead))
## Burg is quite different here, as is OLS (see ar.ols)
ar(ts.union(BJsales, BJsales.lead), method = "burg")
```

---

**ar.ols**

*Fit Autoregressive Models to Time Series by OLS*

**Description**

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.

**Usage**

```r
ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail, 
demean = TRUE, intercept = demean, series, ...)
```

**Arguments**

- `x`: A univariate or multivariate time series.
- `aic`: Logical flag. If `TRUE` then the Akaike Information Criterion is used to choose the order of the autoregressive model. If `FALSE`, the model of order `order.max` is fitted.
- `order.max`: Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where $N$ is the number of observations.
- `na.action`: function to be called to handle missing values.
- `demean`: should the AR model be for `x` minus its mean?
- `intercept`: should a separate intercept term be fitted?
- `series`: names for the series. Defaults to `deparse(substitute(x))`.
- `...`: further arguments to be passed to or from methods.

**Details**

`ar.ols` fits the general AR model to a possibly non-stationary and/or multivariate system of series `x`. The resulting unconstrained least squares estimates are consistent, even if some of the series are non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t$$
where $a_0$ is zero unless intercept is true, and $\mu$ is the sample mean if demean is true, zero otherwise.

Order selection is done by AIC if aic is true. This is problematic, as ar.ols does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if intercept is true and demean is false. Only use this is the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

- **order**: The order of the fitted model. This is chosen by minimizing the AIC if aic = TRUE, otherwise it is order.max.
- **ar**: Estimated autoregression coefficients for the fitted model.
- **var.pred**: The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
- **x.mean**: The estimated mean (or zero if demean is false) of the series used in fitting and for use in prediction.
- **x.intercept**: The intercept in the model for $x \sim x \text{ mean}$, or zero if intercept is false.
- **aic**: The differences in AIC between each model and the best-fitting model. Note that the latter can have an AIC of $-\infty$.
- **n.used**: The number of observations in the time series.
- **order.max**: The value of the order.max argument.
- **partialacf**: NULL. For compatibility with ar.
- **resid**: residuals from the fitted model, conditioning on the first order observations. The first order residuals are set to NA. If x is a time series, so is resid.
- **method**: The character string "Unconstrained LS".
- **series**: The name(s) of the time series.
- **frequency**: The frequency of the time series.
- **call**: The matched call.
- **asy.se.coef**: The asymptotic-theory standard errors of the coefficient estimates.

ARIMA Modelling of Time Series

Description

Fit an ARIMA model to a univariate time series.

Usage

arima(x, order = c(0L, 0L, 0L),
      seasonal = list(order = c(0L, 0L, 0L), period = NA),
      xreg = NULL, include.mean = TRUE,
      transform.pars = TRUE,
      fixed = NULL, init = NULL,
      method = c("CSS-ML", "ML", "CSS"), n.cond,
      SSinit = c("Gardner1980", "Rossignol2011"),
      optim.method = "BFGS",
      optim.control = list(), kappa = 1e6)

Arguments

x 
a univariate time series

order 
A specification of the non-seasonal part of the ARIMA model: the three integer components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.

seasonal 
A specification of the seasonal part of the ARIMA model, plus the period (which defaults to \(\text{frequency}(x)\)). This should be a list with components order and period, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.

xreg 
Optionally, a vector or matrix of external regressors, which must have the same number of rows as \(x\).

include.mean 
Should the ARMA model include a mean/intercept term? The default is TRUE for undifferenced series, and it is ignored for ARIMA models with differencing.

transform.pars 
logical; if true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for method = "CSS". For method = "ML", it has been advantageous to set transform.pars = FALSE in some cases, see also fixed.
**fixed**
optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. `transform.pars = TRUE` will be overridden (with a warning) if any AR parameters are fixed. It may be wise to set `transform.pars = FALSE` when fixing MA parameters, especially near non-invertibility.

**init**
optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in `fixed` will be ignored.

**method**
fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood. Can be abbreviated.

**n.cond**
only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

**SSinit**
a string specifying the algorithm to compute the state-space initialization of the likelihood; see `KalmanLike` for details. Can be abbreviated.

**optim.method**
The value passed as the `method` argument to `optim`.

**optim.control**
List of control parameters for `optim`.

**kappa**
the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.

**Details**
Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition used here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true (the default for an ARMA model), this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If an `xreg` term is included, a linear regression (with a constant term if `include.mean` is true and there is no differencing) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

**Value**
A list of class "Arima" with components:

- **coef**
a vector of AR, MA and regression coefficients, which can be extracted by the `coef` method.

- **sigma2**
the MLE of the innovations variance.

- **var.coef**
the estimated variance matrix of the coefficients `coef`, which can be extracted by the `vcov` method.

- **loglik**
the maximized log-likelihood (of the differenced data), or the approximation to it used.
arma A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.

aic the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.

residuals the fitted innovations.

call the matched call.

series the name of the series x.

code the convergence value returned by optim.

n.cond the number of initial observations not used in the fitting.

nobs the number of “used” observations for the fitting, can also be extracted via nobs() and is used by BIC.

model A list representing the Kalman Filter used in the fitting. See KalmanLike.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner et al (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by kappa). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least 1e4) are excluded from the likelihood calculations. (This gives comparable results to arima0 in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.)

Missing values are allowed, and are handled exactly in method "ML".

If transform.pars is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if transform.pars is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

The results are likely to be different from S-PLUS’s arima.mle, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by arima.mle reverses the signs of the MA coefficients.

arima is very similar to arima0 for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than arima0, particularly for seasonally differenced models.

Simulate from an ARIMA Model

Description

Simulate from an ARIMA model.

Usage

arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
           n.start = NA, start.innov = rand.gen(n.start, ...),
           ...)
Examples

```r
require(graphics)
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
          sd = sqrt(0.1796))
# mildly long-tailed
arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
          rand.gen = function(n, ...) sqrt(0.1796) * rt(n, df = 5))

# An ARIMA simulation
ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)
```

Description

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

Usage

```r
arima0(x, order = c(0, 0, 0),
       seasonal = list(order = c(0, 0, 0), period = NA),
       xreg = NULL, include.mean = TRUE, delta = 0.01,
       transform.pars = TRUE, fixed = NULL, init = NULL,
       method = c("ML", "CSS"), n.cond, optim.control = list())
```

Arguments

- `x`: a univariate time series
- `order`: A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.
- `seasonal`: A specification of the seasonal part of the ARIMA model, plus the period (which defaults to `frequency(x)`). This should be a list with components `order` and `period`, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.
- `xreg`: Optionally, a vector or matrix of external regressors, which must have the same number of rows as `x`.
- `include.mean`: Should the ARIMA model include a mean term? The default is `TRUE` for undifferenced series, `FALSE` for differenced ones (where a mean would not affect the fit nor predictions).
- `delta`: A value to indicate at which point ‘fast recursions’ should be used. See the ‘Details’ section.
- `transform.pars`: Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for `method = "CSS"`. 

ARIMA Modelling of Time Series – Preliminary Version

Arguments

- `x`: a univariate time series
- `order`: A specification of the non-seasonal part of the ARIMA model: the three components \((p, d, q)\) are the AR order, the degree of differencing, and the MA order.
- `seasonal`: A specification of the seasonal part of the ARIMA model, plus the period (which defaults to `frequency(x)`). This should be a list with components `order` and `period`, but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the order.
- `xreg`: Optionally, a vector or matrix of external regressors, which must have the same number of rows as `x`.
- `include.mean`: Should the ARIMA model include a mean term? The default is `TRUE` for undifferenced series, `FALSE` for differenced ones (where a mean would not affect the fit nor predictions).
- `delta`: A value to indicate at which point ‘fast recursions’ should be used. See the ‘Details’ section.
- `transform.pars`: Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for `method = "CSS"`. 

fixed
optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in fixed will be varied. transform.pars = TRUE will be overridden (with a warning) if any ARMA parameters are fixed.

init
optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in fixed will be ignored.

method
Fitting method: maximum likelihood or minimize conditional sum-of-squares. Can be abbreviated.

n.cond
Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

optim.control
List of control parameters for optim.

object
The result of an arima0 fit.

newxreg
New values of xreg to be used for prediction. Must have at least n.ahead rows.

n.ahead
The number of steps ahead for which prediction is required.

se.fit
Logical: should standard errors of prediction be returned?

Arguments passed to or from other methods.

Details
Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The
definition here has

\[ X_t = a_1 X_{t-1} + \cdots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \cdots + b_q e_{t-q} \]

and so the MA coefficients differ in sign from those of S-PLUS. Further, if include.mean is true, this formula applies to \( X - m \) rather than \( X \). For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.

Optimization is done by optim. It will work best if the columns in xreg are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so predict.arima0 will give a warning for non-invertible MA models.

Value
For arima0, a list of class "arima0" with components:

coef
a vector of AR, MA and regression coefficients.

sigma2
the MLE of the innovations variance.

var.coef
the estimated variance matrix of the coefficients coef.

loglik
the maximized log-likelihood (of the differenced data), or the approximation to it used.

arma
A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
arima0

aic    the AIC value corresponding to the log-likelihood. Only valid for method = "ML" fits.
residuals  the fitted innovations.
call    the matched call.
series  the name of the series x.
convergence  the value returned by optim.
n.cond  the number of initial observations not used in the fitting.

For predict.arima0, a time series of predictions, or if se.fit = TRUE, a list with components pred, the predictions, and se, the estimated standard errors. Both components are time series.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the innovations and their variance found by a Kalman filter based on Gardner et al (1980). This has the option to switch to 'fast recursions' (assume an effectively infinite past) if the innovations variance is close enough to its asymptotic bound. The argument delta sets the tolerance: at its default value the approximation is normally negligible and the speed-up considerable. Exact computations can be ensured by setting delta to a negative value.

If transform.pars is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to be invertible during optimization by the same transformation if transform.pars is true. Note that the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models can be fitted by using transform.pars = FALSE and specifying a good set of initial values (often obtainable from a fit with transform.pars = TRUE).

Missing values are allowed, but any missing values will force delta to be ignored and full recursions used. Note that missing values will be propagated by differencing, so the procedure used in this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation n.cond on, (where n.cond is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument n.cond can be used to allow comparability between different fits. The 'part log-likelihood' is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

This is a preliminary version, and will be replaced by arima.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.

The results are likely to be different from S-PLUS's arima.mle, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by arima.mle reverses the signs of the MA coefficients.

**ARMAacf** *Compute Theoretical ACF for an ARMA Process*

**Description**

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

**Usage**

```r
ARMAacf(ar = numeric(), ma = numeric(), lag.max = r, pacf = FALSE)
```
**Arguments**

- **ar**: numeric vector of AR coefficients
- **ma**: numeric vector of MA coefficients
- **lag.max**: integer. Maximum lag required. Defaults to \(\max(p, q+1)\), where \(p, q\) are the numbers of AR and MA terms respectively.
- **pacf**: logical. Should the partial autocorrelations be returned?

**Details**

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags 0, \ldots, \(\max(p, q+1)\), and the remaining autocorrelations are given by a recursive filter.

**Value**

A vector of (partial) autocorrelations, named by the lags.

**References**

as.hclust

Convert Objects to Class hclust

Description

Converts objects from other hierarchical clustering functions to class "hclust".

Usage

as.hclust(x, ...)

Arguments

x       Hierarchical clustering object
...

Details

Currently there is only support for converting objects of class "twins" as produced by the functions diana and agnes from the package cluster. The default method throws an error unless passed an "hclust" object.
asOneSidedFormula

Convert to One-Sided Formula

Description

Names, expressions, numeric values, and character strings are converted to one-sided formulae. If object is a formula, it must be one-sided, in which case it is returned unaltered.

Usage

asOneSidedFormula(object)

Arguments

object a one-sided formula, an expression, a numeric value, or a character string.

Value

a one-sided formula representing object

Author(s)

José Pinheiro and Douglas Bates

formula

Examples

asOneSidedFormula("age")
asOneSidedFormula(~ age)
ave  

Group Averages Over Level Combinations of Factors

Description

Subsets of x[] are averaged, where each subset consist of those observations with the same factor levels.

Usage

ave(x, ..., FUN = mean)

Arguments

x          A numeric.
...
Grouping variables, typically factors, all of the same length as x.
FUN        Function to apply for each factor level combination.

Value

A numeric vector, say y of length length(x). If ... is g1, g2, e.g., y[i] is equal to FUN(x[j], for all j with g1[j] == g1[i] and g2[j] == g2[i]).

ave(breaks, wool)
ave(breaks, tension)
ave(breaks, tension, FUN = function(x) mean(x, trim = 0.1))
plot(breaks, main =
    "ave( Warpbreaks ) for wool x tension combinations")
lines(ave(breaks, wool, tension ), type = "s", col = "blue")
lines(ave(breaks, wool, tension, FUN = median), type = "s", col = "green")
legend(40, 70, c("mean","median"), lty = 1,
    col = c("blue","green"), bg = "gray90")
detach()
Bandwidth Selectors for Kernel Density Estimation

**Description**

Bandwidth selectors for Gaussian kernels in `density`.

**Usage**

`bw.nrd0(x)`

`bw.nrd(x)`

`bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, tol = 0.1 * lower)`

`bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, tol = 0.1 * lower)`

`bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax, method = c("ste", "dpi"), tol = 0.1 * lower)`

**Arguments**

- `x` numeric vector.
- `nb` number of bins to use.
- `lower, upper` range over which to minimize. The default is almost always satisfactory. `hmax` is calculated internally from a normal reference bandwidth.
- `method` either "ste" ("solve-the-equation") or "dpi" ("direct plug-in"). Can be abbreviated.
- `tol` for method "ste", the convergence tolerance for `uniroot`. The default leads to bandwidth estimates with only slightly more than one digit accuracy, which is sufficient for practical density estimation, but possibly not for theoretical simulation studies.

**Details**

`bw.nrd0` implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman’s ‘rule of thumb’, Silverman (1986, page 48, eqn (3.31)) unless the quartiles coincide when a positive result will be guaranteed.

`bw.nrd` is the more common variation given by Scott (1992), using factor 1.06.

`bw.ucv` and `bw.bcv` implement unbiased and biased cross-validation respectively.

`bw.SJ` implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot estimation of derivatives.

The algorithm for method "ste" solves an equation (via `uniroot`) and because of that, enlarges the interval `c(lower, upper)` when the boundaries were not user-specified and do not bracket the root.
The last three methods use all pairwise binned distances: they are of complexity $O(n^2)$ up to $n = nb/2$ and $O(n)$ thereafter. Because of the binning, the results differ slightly when $x$ is translated or sign-flipped.

**Value**

A bandwidth on a scale suitable for the bw argument of density.

**Note**

Long vectors $x$ are not supported, but neither are they by density and kernel density estimation and for more than a few thousand points a histogram would be preferred.

**Author(s)**

B. D. Ripley, taken from early versions of package MASS.

**References**

**See Also**

density.

bandwidth.nrd, ucv, bcv and width.SJ in package MASS, which are all scaled to the width argument of density and so give answers four times as large.

**Examples**

  col = 1:6, lty = 1)
```
Description

Performs Bartlett’s test of the null that the variances in each of the groups (samples) are the same.

Usage

bartlett.test(x, ...)

## Default S3 method:
bartlett.test(x, g, ...)

## S3 method for class 'formula'
bartlett.test(formula, data, subset, na.action, ...)

Arguments

x
a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").

g
a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.

formula
a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data
an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset
an optional vector specifying a subset of observations to be used.

na.action
a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").

... further arguments to be passed to or from methods.

Details

If x is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, g is ignored, and one can simply use bartlett.test(x) to perform the test. If the samples are not yet contained in a list, use bartlett.test(list(x, ...)).

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list of class "htest" containing the following components:

statistic
Bartlett’s K-squared test statistic.

parameter
the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value the p-value of the test.
method the character string "Bartlett test of homogeneity of variances".
data.name a character string giving the names of the data.

References

See Also
*var.test* for the special case of comparing variances in two samples from normal distributions; *fligner.test* for a rank-based (nonparametric) $k$-sample test for homogeneity of variances; *ansari.test* and *mood.test* for two rank based two-sample tests for difference in scale.

Examples
```r
require(graphics)
plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)
```

**Beta**

*The Beta Distribution*

Description
Density, distribution function, quantile function and random generation for the Beta distribution with parameters `shape1` and `shape2` (and optional non-centrality parameter `ncp`).

Usage
```r
dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)
```

Arguments
- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `shape1, shape2` non-negative parameters of the Beta distribution.
- `ncp` non-centrality parameter.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. 

Beta

The Beta Distribution
The Beta distribution with parameters \( \text{shape1} = a \) and \( \text{shape2} = b \) has density

\[
f(x) = \frac{\Gamma(a + b)}{\Gamma(a)\Gamma(b)} x^{a-1}(1 - x)^{b-1}
\]

for \( a > 0, b > 0 \) and \( 0 \leq x \leq 1 \) where the boundary values at \( x = 0 \) or \( x = 1 \) are defined as by continuity (as limits).

The mean is \( a/(a + b) \) and the variance is \( ab/((a + b)^2(a + b + 1)) \). These moments and all distributional properties can be defined as limits (leading to point masses at 0, 1/2, or 1) when \( a \) or \( b \) are zero or infinite, and the corresponding \([dpqr]\text{beta}\) functions are defined correspondingly. pbeta is closely related to the incomplete beta function. As defined by Abramowitz and Stegun

\[
B_x(a, b) = \int_0^x t^{a-1}(1 - t)^{b-1} dt,
\]

and 6.6.2 \( I_x(a, b) = B_x(a, b)/B(a, b) \) where \( B(a, b) = B_1(a, b) \) is the Beta function (beta).

The noncentral Beta distribution (with \( \text{ncp} = \lambda \)) is defined (Johnson et al., 1995, pp. 502) as the distribution of \( X/(X + Y) \) where \( X \sim \chi^2_{2a}(\lambda) \) and \( Y \sim \chi^2_{2b} \).

Value
dbeta gives the density, pbeta the distribution function, qbeta the quantile function, and rbeta generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for rbeta, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying \( \text{ncp} = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm used if \( \text{ncp} \) is omitted. This is to give consistent behaviour in extreme cases with values of \( \text{ncp} \) very near zero.

Source

• The central dbeta is based on a binomial probability, using code contributed by Catherine Loader (see dbinom) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson et al., 1995, pp. 502–3).
$log.p = \text{TRUE}$. For that (log-scale) case, underflow to $-\text{Inf}$ (i.e., $P = 0$) or 0, (i.e., $P = 1$)
still happens because the original algorithm was designed without log-scale considerations.
Underflow to $-\text{Inf}$ now typically signals a warning.

- The non-central pbeta uses a C translation of
  This computes the lower tail only, so the upper tail suffers from cancellation and a warning
  will be given when this is likely to be significant.

- The central case of qbeta is based on a C translation of
  Cran, G. W., K. J. Martin and G. E. Thomas (1977). Remark AS R19 and Algorithm AS 109,

- The central case of rbeta is based on a C translation of

```

---

**binom.test**

*Exact Binomial Test*

**Description**

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

**Usage**

```
binom.test(x, n, p = 0.5,
    alternative = c("two.sided", "less", "greater"),
    conf.level = 0.95)
```

**Arguments**

- `x` number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively.
- `n` number of trials; ignored if `x` has length 2.
- `p` hypothesized probability of success.
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.

**Details**

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least `conf.level`, but in general does not give the shortest-length confidence intervals.
Binomial Value

A list with class "htest" containing the following components:

- **statistic**: the number of successes.
- **parameter**: the number of trials.
- **p.value**: the p-value of the test.
- **conf.int**: a confidence interval for the probability of success.
- **estimate**: the estimated probability of success.
- **null.value**: the probability of success under the null, p.
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the character string "Exact binomial test".
- **data.name**: a character string giving the names of the data.

References

See Also

- **prop.test** for a general (approximate) test for equal or given proportions.

Examples

```r
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that p =
binom.test(c(682, 243), p = 3/4)
binom.test(682, 682 + 243, p = 3/4) # The same.
## => Data are in agreement with the null hypothesis.
```

Binomial The Binomial Distribution

Description

Density, distribution function, quantile function and random generation for the binomial distribution with parameters size and prob.

This is conventionally interpreted as the number of 'successes' in size trials.
Binomial

Usage

dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)

Arguments

x, q
vector of quantiles.

p
vector of probabilities.

n
number of observations. If length(n) > 1, the length is taken to be the number required.
size
number of trials (zero or more).
prob
probability of success on each trial.
log, log.p
logical; if TRUE, probabilities p are given as log(p).
lower.tail
logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

The binomial distribution with size = n and prob = p has density

\[ p(x) = \binom{n}{x} p^x (1 - p)^{n-x} \]

for \( x = 0, \ldots, n \). Note that binomial coefficients can be computed by choose in R.

If an element of x is not integer, the result of dbinom is zero, with a warning.

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

Value
dbinom gives the density, pbinom gives the distribution function, qbinom gives the quantile function and rbinom generates random deviates.

If size is not an integer, NaN is returned.

The length of the result is determined by n for rbinom, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

For dbinom a saddle-point expansion is used: see

pbinom uses pbeta.

qbinom uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rbinom (for size < .Machine$integer.max) is based on
For larger values it uses inversion.

See Also

Distributions for other standard distributions, including dbinom for the negative binomial, and dpois for the Poisson distribution.

Examples

require(graphics)
# Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(dbinom(46:54, 100, 0.5))
## Using "log = TRUE" for an extended range :
n <- 2000
k <- seq(0, n, by = 20)
plot (k, dbinom(k, n, pi/10, log = TRUE), type = "l", ylab = "log density",
main = "dbinom(*, log=TRUE) is better than log(dbinom(*))")
lines(k, log(dbinom(k, n, pi/10)), col = "red", lwd = 2)
## extreme points are omitted since dbinom gives 0.
mtex("dbinom(k, log=TRUE)", adj = 0)
mtex("extended range", adj = 0, line = -1, font = 4)
mtex("log(dbinom(k))", col = "red", adj = 1)

biplot

Biplot of Multivariate Data

Description

Plot a biplot on the current graphics device.

Usage

biplot(x, ...)

## Default S3 method:
biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
  xlabs = NULL, ylabs = NULL, expand = 1,
  xlim = NULL, ylim = NULL, arrow.len = 0.1,
  main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)

Arguments

x     The biplot, a fitted object. For biplot.default, the first set of points (a two-column matrix), usually associated with observations.
y     The second set of points (a two-column matrix), usually associated with variables.
var.axes     If TRUE the second set of points have arrows representing them as (unscaled) axes.
**biplot**

**col**  
A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the `palette`: if there it and the next colour as used, otherwise the first two colours of the palette are used.

**cex**  
The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.

**xlabs**  
A vector of character strings to label the first set of points: the default is to use the row dimname of `x`, or `1:n` if the dimname is `NULL`.

**ylabs**  
A vector of character strings to label the second set of points: the default is to use the row dimname of `y`, or `1:n` if the dimname is `NULL`.

**expand**  
An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.

**arrow.len**  
The length of the arrow heads on the axes plotted in `var.axes` is true. The arrow head can be suppressed by `arrow.len = 0`.

**xlim, ylim**  
Limits for the x and y axes in the units of the first set of variables.

**main, sub, xlab, ylab, ...**  
Graphical parameters.

### Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by `biplot.princomp`. The function `biplot.default` merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to `biplot`: the size of `xlabs` and `ylabs` is controlled by `cex`.

### Side Effects

A plot is produced on the current graphics device.

### References

### See Also

`biplot.princomp`, also for examples.
biplot.princomp  

Biplot for Principal Components

Description

Produces a biplot (in the strict sense) from the output of princomp or prcomp

Usage

### S3 method for class 'prcomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

### S3 method for class 'princomp'
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

Arguments

x  an object of class "princomp".
choices  length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
scale  The variables are scaled by lambda ^ scale and the observations are scaled by lambda ^ (1-scale) where lambda are the singular values as computed by princomp. Normally 0 <= scale <= 1, and a warning will be issued if the specified scale is outside this range.
pc.biplot  If true, use what Gabriel (1971) refers to as a "principal component biplot", with lambda = 1 and observations scaled up by sqrt(n) and variables scaled down by sqrt(n). Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
...  optional arguments to be passed to biplot.default.

Details

This is a method for the generic function biplot. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to pc.biplot = TRUE.

Side Effects

a plot is produced on the current graphics device.

References

See Also

biplot.princomp.
Examples

```r
require(graphics)
biplot(princomp(USArrests))
```

birthday

### Description

Computes answers to a generalised *birthday paradox* problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the smallest number of observations needed to have at least a specified probability of coincidence.

### Usage

```r
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

### Arguments

- `classes` How many distinct categories the people could fall into
- `prob` The desired probability of coincidence
- `n` The number of people
- `coincident` The number of people to fall in the same category

### Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50–50 chance that two or more of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

The formula used is approximate for `coincident > 2`. The approximation is very good for moderate values of `prob` but less good for very small probabilities.

### Value

- `qbirthday` Minimum number of people needed for a probability of at least `prob` that `k` or more of them have the same one out of `classes` equiprobable labels.
- `pbirthday` Probability of the specified coincidence.

### References

Examples

```r
require(graphics)

## the standard version
qbirthday() # 23
## probability of > 2 people with the same birthday
pbirthday(23, coincident = 3)

## examples from Diaconis & Mosteller p. 858.
## 'coincidence' is that husband, wife, daughter all born on the 16th
qbirthday(classes = 30, coincident = 3) # approximately 18
qbirthday(coincident = 4) # exact value 187
qbirthday(coincident = 10) # exact value 1181

## same 4-digit PIN number
qbirthday(classes = 10^4)

## 0.9 probability of three or more coincident birthdays
qbirthday(coincident = 3, prob = 0.9)

## Chance of 4 or more coincident birthdays in 150 people
pbirthday(150, coincident = 4)

## 100 or more coincident birthdays in 1000 people: very rare
pbirthday(1000, coincident = 100)
```

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

Usage

```r
Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)
```

Arguments

- **x**: a numeric vector or univariate time series.
- **lag**: the statistic will be based on lag autocorrelation coefficients.
- **type**: test to be performed: partial matching is used.
- **fitdf**: number of degrees of freedom to be subtracted if `x` is a series of residuals.

Details

These tests are sometimes applied to the residuals from an ARMA(p, q) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting `fitdf = p+q`, provided of course that `lag > fitdf`. 
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic (taking `fitdf` into account).
- **p.value**: the p-value of the test.
- **method**: a character string indicating which type of test was performed.
- **data.name**: a character string giving the name of the data.

Note

Missing values are not handled.

Author(s)

A. Trapletti

References

Examples

```r
x <- rnorm(100)
Box.test(x, lag = 1)
Box.test(x, lag = 1, type = "Ljung")
```

Sets Contrasts for a Factor

Description

Sets the "contrasts" attribute for the factor.

Usage

```r
C(object, contr, how.many, ...)
```

Arguments

- **object**: a factor or ordered factor
- **contr**: which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like `contr.poly` or a character string giving the name of the function
- **how.many**: the number of contrasts to set, by default one less than `nlevels(object)`.
- **...**: additional arguments for the function `contr`.
Details

For compatibility with S, contr can be treatment, helmert, sum or poly (without quotes) as shorthand for contr.treatment and so on.

Value

The factor object with the "contrasts" attribute set.

References

See Also

contrasts, contr.sum, etc.

Examples

## reset contrasts to defaults
options(contrasts = c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data = warpbreaks)
## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base = 2), data = warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
               C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)

---

cancor  Canonical Correlations

Description

Compute the canonical correlations between two data matrices.

Usage

cancor(x, y, xcenter = TRUE, ycenter = TRUE)

Arguments

x  numeric matrix \((n \times p_1)\), containing the x coordinates.
y  numeric matrix \((n \times p_2)\), containing the y coordinates.
cancor

xcenter

logical or numeric vector of length $p_1$, describing any centering to be done on the x values before the analysis. If TRUE (default), subtract the column means. If FALSE, do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.

ycenter

analogous to xcenter, but for the y values.

Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

Value

A list containing the following components:

- cor: correlations.
- xcoef: estimated coefficients for the x variables.
- ycoef: estimated coefficients for the y variables.
- xcenter: the values used to adjust the x variables.
- ycenter: the values used to adjust the x variables.

References

qr, svd.

Examples

## signs of results are random
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))
all(abs(cor(x %*% cxy$xcoef, y %*% cxy$ycoef)[,1:3] - diag(cxy $ cor)) < 1e-15)
all(abs(cor(x %*% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %*% cxy$ycoef) - diag(5)) < 1e-15)
Case and Variable Names of Fitted Models

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

Usage

```r
case.names(object, ...)  
## S3 method for class 'lm'

variable.names(object, ...)  
## S3 method for class 'lm'
```

Arguments

- `object`: an R object, typically a fitted model.
- `full`: logical; if TRUE, all names (including zero weights, …) are returned.
- `...`: further arguments passed to or from other methods.

Value

A character vector.

See Also

`lm`; further, `all.names`, `all.vars` for functions with a similar name but only slightly related purpose.

Examples

```r
x <- 1:20
y <- setNames(x + (x/4 - 2)^3 + rnorm(20, sd = 3),
             paste("O", x, sep = "."))
ww <- rep(1, 20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2), weights = ww),
cor = TRUE)
variable.names(lmxy)
variable.names(lmxy, full = TRUE)  # includes the last
case.names(lmxy)
case.names(lmxy, full = TRUE)  # includes the 0-weight case
```
The Cauchy Distribution

Description

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter location and scale parameter scale.

Usage

dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are not specified, they assume the default values of 0 and 1 respectively.
The Cauchy distribution with location \( l \) and scale \( s \) has density

\[
f(x) = \frac{1}{\pi s} \left(1 + \left(\frac{x - l}{s}\right)^2\right)^{-1}
\]

for all \( x \).

Value

dcauchy, pcauchy, and qcauchy are respectively the density, distribution function and quantile function of the Cauchy distribution. rcauchy generates random deviates from the Cauchy.
The length of the result is determined by \( n \) for rcauchy, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dcauchy, pcauchy and qcauchy are all calculated from numerically stable versions of the definitions.
rcauchy uses inversion.

dcauchy(-1:4)

---

### chisq.test

**Pearson’s Chi-squared Test for Count Data**

**Description**

`chisq.test` performs chi-squared contingency table tests and goodness-of-fit tests.

**Usage**

```r
chisq.test(x, y = NULL, correct = TRUE,
            p = rep(1/length(x), length(x)), rescale.p = FALSE,
            simulate.p.value = FALSE, B = 2000)
```

**Arguments**

- **x**
  - a numeric vector or matrix. `x` and `y` can also both be factors.

- **y**
  - a numeric vector; ignored if `x` is a matrix. If `x` is a factor, `y` should be a factor of the same length.

- **correct**
  - a logical indicating whether to apply continuity correction when computing the test statistic for 2 by 2 tables: one half is subtracted from all `|O - E|` differences; however, the correction will not be bigger than the differences themselves. No correction is done if `simulate.p.value = TRUE`.

- **p**
  - a vector of probabilities of the same length of `x`. An error is given if any entry of `p` is negative.

- **rescale.p**
  - a logical scalar; if TRUE then `p` is rescaled (if necessary) to sum to 1. If `rescale.p` is FALSE, and `p` does not sum to 1, an error is given.

- **simulate.p.value**
  - a logical indicating whether to compute p-values by Monte Carlo simulation.

- **B**
  - an integer specifying the number of replicates used in the Monte Carlo test.
Details

If \( x \) is a matrix with one row or column, or if \( x \) is a vector and \( y \) is not given, then a \textit{goodness-of-fit test} is performed (\( x \) is treated as a one-dimensional contingency table). The entries of \( x \) must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in \( p \), or are all equal if \( p \) is not given.

If \( x \) is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table: the entries of \( x \) must be non-negative integers. Otherwise, \( x \) and \( y \) must be vectors or factors of the same length; cases with missing values are removed, the objects are coerced to factors, and the contingency table is computed from these. Then Pearson’s chi-squared test is performed of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals.

If \( \text{simulate.p.value} \) is \text{FALSE}, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if \( \text{correct} = \text{TRUE} \), the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with \( B \) replicates.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation assumed for the chi-squared test but rather that for Fisher’s exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by \( p \), each sample being of size \( n = \sum(x) \). This simulation is done in R and may be slow.

Value

A list with class “htest” containing the following components:

- **statistic**
  the value the chi-squared test statistic.

- **parameter**
  the degrees of freedom of the approximate chi-squared distribution of the test statistic, \( \text{NA} \) if the p-value is computed by Monte Carlo simulation.

- **p.value**
  the p-value for the test.

- **method**
  a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.

- **data.name**
  a character string giving the name(s) of the data.

- **observed**
  the observed counts.

- **expected**
  the expected counts under the null hypothesis.

- **residuals**
  the Pearson residuals, \((\text{observed} - \text{expected}) / \sqrt{\text{expected}}\).

- **stdres**
  standardized residuals, \((\text{observed} - \text{expected}) / \sqrt{V}\), where \( V \) is the residual cell variance (Agresti, 2007, section 2.4.5 for the case where \( x \) is a matrix, \( n \times p \times (1 - p) \) otherwise).

Source

The code for Monte Carlo simulation is a C translation of the Fortran algorithm of Patefield (1981).

**Examples**

```r
## From Agresti(2007) p.39
M <- as.table(rbind(c(762, 327, 468), c(484, 239, 477)))
dimnames(M) <- list(gender = c("F", "M"),
                    party = c("Democrat","Independent", "Republican"))
(Xsq <- chisq.test(M)) # Prints test summary
Xsq$observed  # observed counts (same as M)
Xsq$expected  # expected counts under the null
Xsq$residuals # Pearson residuals
Xsq$stdres    # standardized residuals
```

```r
## Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), ncol = 2)
chisq.test(x)$p.value # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value # around 0.29!
```

```r
## Testing for population probabilities
## Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x)) # the same
x <- c(89,37,30,28,2)
p <- c(40,20,20,15,5)
try(
  chisq.test(x, p = p) # gives an error
)
chisq.test(x, p = p, rescale.p = TRUE) # works
  p <- c(0.40,0.20,0.20,0.19,0.01)
  # Expected count in category 5
  # is 1.86 < 5 ==> chi square approx.
chisq.test(x, p = p) # maybe doubtful, but is ok!
chisq.test(x, p = p, simulate.p.value = TRUE)
```

```r
## Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x)) # NOT 'chisq.test(x)'
```

---

**Chisquare**

*The (non-central) Chi-Squared Distribution*
Description

Density, distribution function, quantile function and random generation for the chi-squared ($\chi^2$) distribution with $df$ degrees of freedom and optional non-centrality parameter $ncp$.

Usage

dchisq(x, df, ncp = 0, log = FALSE)
pchisq(q, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp = 0)

Arguments

$x, q$  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number required.
df  degrees of freedom (non-negative, but can be non-integer).
ncp  non-centrality parameter (non-negative).
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The chi-squared distribution with df = $n \geq 0$ degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2}\Gamma(n/2)} x^{n/2-1} e^{-x/2}$$

for $x > 0$. The mean and variance are $n$ and $2n$.

The non-central chi-squared distribution with df = $n$ degrees of freedom and non-centrality parameter $ncp = \lambda$ has density

$$f(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$

for $x \geq 0$. For integer $n$, this is the distribution of the sum of squares of $n$ normals each with variance one, $\lambda$ being the sum of squares of the normal means; further, $E(X) = n + \lambda$, $Var(X) = 2(n + 2 * \lambda)$, and $E((X - E(X))^3) = 8(n + 3 * \lambda)$.

Note that the degrees of freedom df = $n$, can be non-integer, and also $n = 0$ which is relevant for non-centrality $\lambda > 0$, see Johnson et al (1995, chapter 29). In that (noncentral, zero df) case, the distribution is a mixture of a point mass at $x = 0$ (of size pchisq(0, df=0, ncp=ncp)) and a continuous part, and dchisq() is not a density with respect to that mixture measure but rather the limit of the density for df $\to$ 0.

Note that ncp values larger than about 1e5 may give inaccurate results with many warnings for pchisq and qchisq.
**Value**

dchisq gives the density, pchisq gives the distribution function, qchisq gives the quantile function, and rchisq generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rchisq, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

Supplying ncp = 0 uses the algorithm for the non-central distribution, which is not the same algorithm used if ncp is omitted. This is to give consistent behaviour in extreme cases with values of ncp very near zero.

The code for non-zero ncp is principally intended to be used for moderate values of ncp: it will not be highly accurate, especially in the tails, for large values.

**Source**

The central cases are computed via the gamma distribution.

The non-central dchisq and rchisq are computed as a Poisson mixture central of chi-squares (Johnson et al. 1995, p.436).

which computes the lower tail only (so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant).

The non-central qchisq is based on inversion of pchisq.

**References**

**See Also**

Distributions for other standard distributions.

A central chi-squared distribution with n degrees of freedom is the same as a Gamma distribution with shape $\alpha = n/2$ and scale $\sigma = 2$. Hence, see dgamma for the Gamma distribution.

**Examples**

```r
require(graphics)

dchisq(1, df = 1:3)
pchisq(1, df = 3)
pchisq(1, df = 3, ncp = 0:4) # includes the above
```
cmdscale

Classical (Metric) Multidimensional Scaling

Description

Classical multidimensional scaling (MDS) of a data matrix. Also known as principal coordinates analysis (Gower, 1966).

Usage

```r
cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE,
    list. = eig || add || x.ret)
```

Arguments

d a distance structure such as that returned by `dist` or a full symmetric matrix containing the dissimilarities.

k the maximum dimension of the space which the data are to be represented in; must be in \{1, 2, ..., n - 1\}.

eig indicates whether eigenvalues should be returned.
cmdscale

add
logical indicating if an additive constant $c^*$ should be computed, and added to the non-diagonal dissimilarities such that the modified dissimilarities are Euclidean.

x.ret
indicates whether the doubly centred symmetric distance matrix should be returned.

list.
logical indicating if a list should be returned or just the $n \times k$ matrix, see ‘Value’.

Details
Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities. (It is a major part of what ecologists call ‘ordination’.)

A set of Euclidean distances on $n$ points can be represented exactly in at most $n - 1$ dimensions. cmdscale follows the analysis of Mardia (1978), and returns the best-fitting $k$-dimensional representation, where $k$ may be less than the argument $k$.

The representation is only determined up to location (cmdscale takes the column means of the configuration to be at the origin), rotations and reflections. The configuration returned is given in principal-component axes, so the reflection chosen may differ between R platforms (see prcomp).

When add = TRUE, a minimal additive constant $c^*$ is computed such that the dissimilarities $d_{ij} + c^*$ are Euclidean and hence can be represented in $n - 1$ dimensions. Whereas S (Becker et al, 1988) computes this constant using an approximation suggested by Torgerson, R uses the analytical solution of Cailliez (1983), see also Cox and Cox (2001). Note that because of numerical errors the computed eigenvalues need not all be non-negative, and even theoretically the representation could be in fewer than $n - 1$ dimensions.

Value
If .list is false (as per default), a matrix with $k$ columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

points
a matrix with up to $k$ columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

eig
the $n$ eigenvalues computed during the scaling process if eig is true. NB: versions of R before 2.12.1 returned only $k$ but were documented to return $n - 1$.

x
the doubly centered distance matrix if x.ret is true.

ac
the additive constant $c^*$, 0 if add = FALSE.

GOF
a numeric vector of length 2, equal to say $(g_1, g_2)$, where $g_i = (\sum_{j=1}^{k} \lambda_j)/(\sum_{j=1}^{n} T_i(\lambda_j))$, where $\lambda_j$ are the eigenvalues (sorted in decreasing order), $T_1(v) = |v|$, and $T_2(v) = max(v, 0)$.

References

dist.

isoMDS and sammon in package MASS provide alternative methods of multidimensional scaling.

Examples

```r
require(graphics)

loc <- cmdscale(eurodist)
x <- loc[, 1]
y <- -loc[, 2] # reflect so North is at the top
## note asp = 1, to ensure Euclidean distances are represented correctly
plot(x, y, type = "n", xlab = "", ylab = "", asp = 1, axes = FALSE,
     main = "cmdscale(eurodist)")
text(x, y, rownames(loc), cex = 0.6)
```

Description

c coef is a generic function which extracts model coefficients from objects returned by modeling functions. coefficients is an alias for it.

Usage

c coef(object, 

coefficients(object, 

## Default S3 method:
c coef(object, complete = TRUE, 

## S3 method for class 'aov'
c coef(object, complete = FALSE, 

```
**complete.cases**

**Arguments**

- `object`: an object for which the extraction of model coefficients is meaningful.
- `complete`: for the default (used for `lm`, etc) and `aov` methods: logical indicating if the full coefficient vector should be returned also in case of an over-determined system where some coefficients will be set to `NA`, see also `alias`. Note that the default differs for `lm()` and `aov()` results.
- `...`: other arguments.

**Details**

All object classes which are returned by model fitting functions should provide a `coef` method or use the default one. (Note that the method is for `coef` and not `coefficients`.)

The “aov” method does not report aliased coefficients (see `alias`) by default where `complete = FALSE`.

The complete argument also exists for compatibility with `vcov` methods, and `coef` and `aov` methods for other classes should typically also keep the `complete = *` behavior in sync. By that, with `p <- length(coef(obj, complete = TF)), dim(vcov(obj, complete = TF)) == c(p, p)` will be fulfilled for both complete settings and the default.

**Value**

Coefficients extracted from the model object `object`.

For standard model fitting classes this will be a named numeric vector. For "maov" objects (produced by `aov`) it will be a matrix.

**References**

**See Also**

`fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.

**Examples**

```r
x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))
```

---

**complete.cases**

**Find Complete Cases**

**Description**

Return a logical vector indicating which cases are complete, i.e., have no missing values.

**Usage**

```r
complete.cases(...)
```

**Arguments**

- `...`: a sequence of vectors, matrices and data frames.
**Value**

A logical vector specifying which observations/rows have no missing values across the entire sequence.

**Note**

A current limitation of this function is that it uses low level functions to determine lengths and missingness, ignoring the class. This will lead to spurious errors when some columns have classes with `length` or `is.na` methods, for example "POSIXlt", as described in PR#16648.

**See Also**

`is.na`, `na.omit`, `na.fail`.

**Examples**

```r
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
```

---

**Description**

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

**Usage**

```r
confint(object, parm, level = 0.95, ...)
```

**Arguments**

- `object`: a fitted model object.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required.
- `...`: additional argument(s) for methods.
Details

`confint` is a generic function. The default method assumes asymptotic normality, and needs suitable `coef` and `vcov` methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on $t$ values are used.

There are stub methods in package `stats` for classes "glm" and "nls" which call those in package `MASS` (if installed): if the `MASS` namespace has been loaded, its methods will be used directly. (Those methods are based on profile likelihood.)

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1-level)/2 and 1 - (1-level)/2 in % (by default 2.5% and 97.5%).

See Also

`confint.glm` and `confint.nls` in package `MASS`.

Examples

```r
fit <- lm(100/mpg ~ disp + hp + wt + am, data = mtcars)
confint(fit)
confint(fit, "wt")
```

```r
## from example(glm)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3, 1, 9); treatment <- gl(3, 3)
glm.D93 <- glm(counts ~ outcome + treatment, family = poisson())
confint(glm.D93) # needs MASS to be installed
confint.default(glm.D93) # based on asymptotic normality
```

---

## constrOptim

### Linearly Constrained Optimization

**Description**

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

**Usage**

```r
constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
outer.iterations = 100, outer.eps = 1e-05, ..., 

hessian = FALSE)
```

**Arguments**

- `theta` numeric (vector) starting value (of length $p$): must be in the feasible region.
- `f` function to minimise (see below).
- `grad` gradient of $f$ (a `function` as well), or `NULL` (see below).
ui
/ constraint matrix \( (k \times p) \), see below.

\( ci \)
/ constraint vector of length \( k \) (see below).

\( mu \)
/ (Small) tuning parameter.

control, method, hessian
/ passed to \texttt{optim}.

\texttt{outer.iterations}
/ iterations of the barrier algorithm.

\texttt{outer.\v{e}ps}
/ non-negative number; the relative convergence tolerance of the barrier algo-

\( ... \)
/ Other named arguments to be passed to \texttt{f} and \texttt{grad}: needs to be passed through \texttt{optim} so should not match its argument names.

\textbf{Details}

The feasible region is defined by \( ui \ %*% theta - ci \geq 0 \). The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then \texttt{optim} is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter \( mu \) multiplies the barrier term. Its precise value is often relatively unimportant. As \( mu \) increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any \texttt{optim} method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function \( f \) takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments \( ... \) will be passed to \texttt{optim} and then (if not used by \texttt{optim}) to \( f \). As with \texttt{optim}, the default is to minimise, but maximisation can be performed by setting \texttt{control$fnscale} to a negative value.

The gradient function \( \texttt{grad} \) must be supplied except with \texttt{method = "Nelder-Mead"}. It should take arguments matching those of \( f \) and return a vector containing the gradient.

\textbf{Value}

As for \texttt{optim}, but with two extra components: \texttt{barrier.value} giving the value of the barrier function at the optimum and \texttt{outer.iterations} gives the number of outer iterations (calls to \texttt{optim}). The \texttt{counts} component contains the \textit{sum} of all \texttt{optim()}\$\texttt{counts}.

\textbf{References}

K. Lange \textit{Numerical Analysis for Statisticians}. Springer 2001, p185ff

\textbf{See Also}

\texttt{optim}, especially \texttt{method = "L-BFGS-B"} which does box-constrained optimisation.
Examples

```r
## from optim
fr <- function(x) { ## Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) { ## Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
     200 * (x2 - x1 * x1))
}
optim(c(-1.2, 1), fr, grr)
# Box-constraint, optimum on the boundary
constrOptim(c(-1.2, 0.9), fr, grr, ui = rbind(c(-1, 0), c(0, -1)), ci = c(-1, -1))
# x <= 0.9, y - x > 0.1
constrOptim(c(.5, 0), fr, grr, ui = rbind(c(-1, 0), c(1, -1)), ci = c(-0.9, 0.1))

## Solves linear and quadratic programming problems
## but needs a feasible starting value
# from example(solve.QP) in 'quadprog'
# no derivative
fQP <- function(b) {-sum(c(0, 5, 0)*b)+0.5*sum(b*b)}
Amat <- matrix(c(-4, -3, 0, 2, 1, 0, 0, -2, 1), 3, 3)
bvec <- c(-8, 2, 0)
constrOptim(c(2,-1,-1), fQP, NULL, ui = t(Amat), ci = bvec)
# derivative
gQP <- function(b) {-c(0, 5, 0) + b}
constrOptim(c(2,-1,-1), fQP, gQP, ui = t(Amat), ci = bvec)

## Now with maximisation instead of minimisation
hQP <- function(b) {sum(c(0, 5, 0)*b)-0.5*sum(b*b)}
constrOptim(c(2,-1,-1), hQP, NULL, ui = t(Amat), ci = bvec,
            control = list(fnscale = -1))
```

### Contrast Matrices

---

#### Description

Return a matrix of contrasts.

#### Usage

- `contr.helmert(n, contrasts = TRUE, sparse = FALSE)`
- `contr.poly(n, scores = 1:n, contrasts = TRUE, sparse = FALSE)`
- `contr.sum(n, contrasts = TRUE, sparse = FALSE)`
- `contr.treatment(n, base = 1, contrasts = TRUE, sparse = FALSE)`
- `contr.SAS(n, contrasts = TRUE, sparse = FALSE)`
Arguments

n: a vector of levels for a factor, or the number of levels.
contrasts: a logical indicating whether contrasts should be computed.
sparse: logical indicating if the result should be sparse (of class dgCMatrix), using package Matrix.
scores: the set of values over which orthogonal polynomials are to be computed.
base: an integer specifying which group is considered the baseline group. Ignored if contrasts is FALSE.

details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with n levels. The returned value contains the computed contrasts. If the argument contrasts is FALSE a square indicator matrix (the dummy coding) is returned except for contr.poly (which includes the 0-degree, i.e. constant, polynomial when contrasts = FALSE).

contr.helmert returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. contr.poly returns contrasts based on orthogonal polynomials. contr.sum uses ‘sum to zero contrasts’.

contr.treatment contrasts each level with the baseline level (specified by base): the baseline level is omitted. Note that this does not produce ‘contrasts’ as defined in the standard theory for linear models as they are not orthogonal to the intercept.

contr.SAS is a wrapper for contr.treatment that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

For consistency, sparse is an argument to all these contrast functions, however sparse = TRUE for contr.poly is typically pointless and is rarely useful for contr.helmert.

Value

A matrix with n rows and k columns, with k=n-1 if contrasts is TRUE and k=n if contrasts is FALSE.

References

See Also

contrasts, C, and aov, glm, lm.

Examples

(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: even orthonormal
contrasts

(cT. <- contr.SAS(5))
all(crossprod(cT.) == diag(4)) # TRUE

zapsmall(cP <- contr.poly(3)) # Linear and Quadratic
zapsmall(crossprod(cP), digits = 15) # orthonormal up to fuzz

contrasts
Get and Set Contrast Matrices

Description

Set and view the contrasts associated with a factor.

Usage

contrasts(x, contrasts = TRUE, sparse = FALSE)
contrasts(x, how.many) <- value

Arguments

x                a factor or a logical variable.
contrasts        logical. See ‘Details’.
sparse           logical indicating if the result should be sparse (of class dgCMatrix), using package Matrix.
how.many         How many contrasts should be made. Defaults to one less than the number of levels of x. This need not be the same as the number of columns of value.
value             either a numeric matrix (or a sparse or dense matrix of a class extending dMatrix from package Matrix) whose columns give coefficients for contrasts in the levels of x, or the (quoted) name of a function which computes such matrices.

Details

If contrasts are not set for a factor the default functions from options("contrasts") are used.

A logical vector x is converted into a two-level factor with levels c(FALSE, TRUE) (regardless of which levels occur in the variable).

The argument contrasts is ignored if x has a matrix contrasts attribute set. Otherwise if contrasts = TRUE it is passed to a contrasts function such as contr.treatment and if contrasts = FALSE an identity matrix is returned. Suitable functions have a first argument which is the character vector of levels, a named argument contrasts (always called with contrasts = TRUE) and optionally a logical argument sparse.

If value supplies more than how.many contrasts, the first how.many are used. If too few are supplied, a suitable contrast matrix is created by extending value after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

References

convolve

Convolution of Sequences via FFT

Description

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

Usage

convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))

Arguments

x, y numeric sequences of the same length to be convolved.
conj logical; if TRUE, take the complex conjugate before back-transforming (default, and used for usual convolution).
type character; partially matched to "circular", "open", "filter". For "circular", the two sequences are treated as circular, i.e., periodic. For "open" and "filter", the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of x with weights y.

Details

The Fast Fourier Transform, fft, is used for efficiency.

The input sequences x and y must have the same length if circular is true.

Note that the usual definition of convolution of two sequences x and y is given by convolve(x, rev(y), type = "o").

Examples

utils::example(factor)
fff <- ff[, drop = TRUE] # reduce to 5 levels.
contrasts(fff) # treatment contrasts by default
contrasts(C(fff, sum))
contrasts(fff, contrasts = FALSE) # the 5x5 identity matrix
contrasts(fff) <- contr.sum(5); contrasts(fff) # set sum contrasts
contrasts(fff, 2) <- contr.sum(5); contrasts(fff) # set 2 contrasts
# supply 2 contrasts, compute 2 more to make full set of 4.
contrasts(fff) <- contr.sum(5)[, 1:2]; contrasts(fff)
# # using sparse contrasts: % useful, once model.matrix() works with these :
ffs <- fff
contrasts(ffs) <- contr.sum(5, sparse = TRUE)[, 1:2]; contrasts(ffs)
stopifnot(all.equal(ffs, fff))
contrasts(ffs) <- contr.sum(5, sparse = TRUE); contrasts(ffs)
Value

If \( r <- \text{convolve}(x, y, \text{type} = \text{"open"}) \) and \( n <- \text{length}(x), m <- \text{length}(y) \), then

\[
r_k = \sum_i x_{k-m+i}y_i
\]

where the sum is over all valid indices \( i \), for \( k = 1, \ldots, n + m - 1 \).

If \( \text{type} = \text{"circular"} \), \( n = m \) is required, and the above is true for \( i, k = 1, \ldots, n \) when \( x_j := x_{n+j} \) for \( j < 1 \).

require(graphics)
x <- c(0,0,0,100,0,0,0)
y <- c(0,0,1,2,1,0,0)/4
zapsmall(convolve(x, y)) # *NOT* what you first thought.
zapsmall(convolve(x, y[3:5], type = "f")) # rather
x <- rnorm(50)
y <- rnorm(50)
# Circular convolution *has* this symmetry:
all.equal(convolve(x, y, conj = FALSE), rev(convolve(rev(y),x)))

n <- length(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8
Han <- function(y) # Hanning
    convolve(y, c(1,2,1)/4, type = "filter")
plot(x, y, main = "Using \texttt{convolve(.) for Hanning filters}"
lines(x[-c(1 , n)], Han(y), col = "red")
lines(x[-c(1:2, (n-1):n)], Han(Han(y)), lwd = 2, col = "dark blue")
```

cophenetic

Cophenetic Distances for a Hierarchical Clustering

Description

Computes the cophenetic distances for a hierarchical clustering.
**Usage**

cophenetic(x)

## Default S3 method:
cophenetic(x)

## S3 method for class 'dendrogram'
cophenetic(x)

**Arguments**

x

an R object representing a hierarchical clustering. For the default method, an object of class "hclust" or with a method for as.hclust() such as "agnes" in package cluster.

**Details**

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

cophenetic is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an as.hclust() or, more directly, a cophenetic() method for such a class.

The method for objects of class "dendrogram" requires that all leaves of the dendrogram object have non-null labels.

**Value**

An object of class "dist".

cor(d0, d.coph) # 0.9911

cor

Correlation, Variance and Covariance (Matrices)

Description

var, cov and cor compute the variance of x and the covariance or correlation of x and y if these are vectors. If x and y are matrices then the covariances (or correlations) between the columns of x and the columns of y are computed.

cov2cor scales a covariance matrix into the corresponding correlation matrix efficiently.

Usage

```r
var(x, y = NULL, na.rm = FALSE, use)
cov(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cor(x, y = NULL, use = "everything", method = c("pearson", "kendall", "spearman"))
cov2cor(V)
```

Arguments

- **x**: a numeric vector, matrix or data frame.
- **y**: NULL (default) or a vector, matrix or data frame with compatible dimensions to x. The default is equivalent to y = x (but more efficient).
- **na.rm**: logical. Should missing values be removed?
- **use**: an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".
- **method**: a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman": can be abbreviated.
- **V**: symmetric numeric matrix, usually positive definite such as a covariance matrix.
Details

For \texttt{cov} and \texttt{cor} one must either give a matrix or data frame for \texttt{x} or give both \texttt{x} and \texttt{y}.

The inputs must be numeric (as determined by \texttt{is.numeric}: logical values are also allowed for historical compatibility): the "kendall" and "spearman" methods make sense for ordered inputs but \texttt{xtfrm} can be used to find a suitable prior transformation to numbers.

\texttt{var} is just another interface to \texttt{cov}, where \texttt{na.rm} is used to determine the default for use when that is unspecified. If \texttt{na.rm} is \texttt{TRUE} then the complete observations (rows) are used (use = "na.or.complete") to compute the variance. Otherwise, by default use = "everything".

If use is "everything", NAs will propagate conceptually, i.e., a resulting value will be NA whenever one of its contributing observations is NA.

If use is "all.obs", then the presence of missing observations will produce an error. If use is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if use has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there are no complete pairs for that pair of variables. For \texttt{cov} and \texttt{var}, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) \texttt{var} (double(0), use = ") gives NA for use = "everything" and "na.or.complete", and gives an error in the other cases.

The denominator \( n - 1 \) is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return \texttt{NA} when there is only one observation (whereas S-PLUS has been returning NaN), and fail if \texttt{x} has length zero.

For \texttt{cor()}, if method is "kendall" or "spearman", Kendall's \( \tau \) or Spearman's \( \rho \) statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For \texttt{cov()}, a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes \texttt{cor}(R(x), R(y)) (or \texttt{cov}(., .)) where \( R(u) := \text{rank}(u, \text{na.last} = "keep") \). In the case of missing values, the ranks are calculated depending on the value of use, either based on complete observations, or based on pairwise completeness with reranking for each pair.

When there are ties, Kendall's \( \tau_b \) is computed, as proposed by Kendall (1945).

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using \texttt{sweep}(., FUN = "/") twice. The \texttt{cov2cor} function is even a bit more efficient, and provided mostly for didactical reasons.

Value

For \( r <- \text{cor}(\ast, \text{use} = \"all.obs\)\), it is now guaranteed that all(abs(r) <= 1).

Note

Some people have noted that the code for Kendall's tau is slow for very large datasets (many more than 1000 cases). It rarely makes sense to do such a computation, but see function \texttt{cor.fk} in package \texttt{pcaPP}.

## but "complete" is closer in Eigen space:
EV <- function(m) eigen(m, only.values=TRUE)$values
summary(abs(1 - EV(Rp)/EV(R.)) / abs(1 - EV(Rc)/EV(R.)))

---

**cor.test**  
*Test for Association/Correlation Between Paired Samples*

**Description**

Test for association between paired samples, using one of Pearson’s product moment correlation coefficient, Kendall’s \( \tau \) or Spearman’s \( \rho \).

**Usage**

```r
 cor.test(x, ...)  
```

**Arguments**

- **x, y** numeric vectors of data values. \( x \) and \( y \) must have the same length.
- **alternative** indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.
- **method** a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.
- **exact** a logical indicating whether an exact p-value should be computed. Used for Kendall’s \( \tau \) and Spearman’s \( \rho \). See ‘Details’ for the meaning of NULL (the default).
- **conf.level** confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.
cor.test

continuity logical: if true, a continuity correction is used for Kendall’s $\tau$ and Spearman’s $\rho$ when not computed exactly.

formula a formula of the form $\sim u + v$, where each of $u$ and $v$ are numeric variables giving the data values for one sample. The samples must be of the same length.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... further arguments to be passed to or from methods.

Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range $[-1,1]$ with 0 indicating no association. These are sometimes referred to as tests of no correlation, but that term is often confined to the default method.

If method is "pearson", the test statistic is based on Pearson’s product moment correlation coefficient $\text{cor}(x, y)$ and follows a $t$ distribution with $\text{length}(x) - 2$ degrees of freedom if the samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher’s $Z$ transform.

If method is "kendall" or "spearman", Kendall’s $\tau$ or Spearman’s $\rho$ statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall’s test, by default (if exact is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman’s test, p-values are computed using algorithm AS 89 for $n < 1290$ and exact = TRUE, otherwise via the asymptotic $t$ approximation. Note that these are ‘exact’ for $n < 10$, and use an Edgeworth series approximation for larger sample sizes (the cutoff has been changed from the original paper).

Value

A list with class "htest" containing the following components:

- statistic the value of the test statistic.
- parameter the degrees of freedom of the test statistic in the case that it follows a $t$ distribution.
- p.value the p-value of the test.
- estimate the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
- null.value the value of the association measure under the null hypothesis, always 0.
- alternative a character string describing the alternative hypothesis.
- method a character string describing the alternative hypothesis.
- data.name a character string indicating how the association was measured.
- conf.int a confidence interval for the measure of association. Currently only given for Pearson’s product moment correlation coefficient in case of at least 4 complete pairs of observations.

Examples

## Assessment of tuna quality. We compare the Hunter L measure of
## lightness to the averages of consumer panel scores (recoded as
## integer values from 1 to 6 and averaged over 80 such values) in
## 9 lots of canned tuna.

x <- c(44.4, 45.9, 41.9, 53.3, 44.7, 44.1, 50.7, 45.2, 60.1)
y <- c(2.6, 3.1, 2.5, 5.0, 3.6, 4.0, 5.2, 2.8, 3.8)

## The alternative hypothesis of interest is that the
## Hunter L value is positively associated with the panel score.

cor.test(x, y, method = "kendall", alternative = "greater")
## => p=0.05972

cor.test(x, y, method = "kendall", alternative = "greater",
exact = FALSE) # using large sample approximation
## => p=0.04765

## Compare this to
cor.test(x, y, method = "spearman", alternative = "g")
cor.test(x, y, alternative = "g")

## Formula interface.
require(graphics)
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)

---

cov.wt

### Weighted Covariance Matrices

**Description**

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

**Usage**

```
cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
    method = c("unbiased", "ML"))
```
Arguments

- **x**: a matrix or data frame. As usual, rows are observations and columns are variables.
- **wt**: a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of `x`.
- **cor**: a logical indicating whether the estimated correlation weighted matrix will be returned as well.
- **center**: either a logical or a numeric vector specifying the centers to be used when computing covariances. If TRUE, the (weighted) mean of each variable is used, if FALSE, zero is used. If center is numeric, its length must equal the number of columns of `x`.
- **method**: string specifying how the result is scaled, see ‘Details’ below. Can be abbreviated.

Details

By default, method = “unbiased”, The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default (1/n) the conventional unbiased estimate of the covariance matrix with divisor (n − 1) is obtained. This differs from the behaviour in S-PLUS which corresponds to method = “ML” and does not divide.

Value

A list containing the following named components:

- **cov**: the estimated (weighted) covariance matrix
- **center**: an estimate for the center (mean) of the data.
- **n.obs**: the number of observations (rows) in `x`.
- **wt**: the weights used in the estimation. Only returned if given as an argument.
- **cor**: the estimated correlation matrix. Only returned if `cor` is TRUE.

See Also

`cov` and `var`.

Examples

```r
(xy <- cbind(x = 1:10, y = c(1:3, 8:5, 8:10)))
w1 <- c(0,0,0,1,1,1,1,1,0,0)
cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```
Description

Plots a cumulative periodogram.

Usage

```r
cpgram(ts, taper = 0.1,
       main = paste("Series: ", deparse(substitute(ts)),
       ci.col = "blue")
```

Arguments

- `ts`: a univariate time series
- `taper`: proportion tapered in forming the periodogram
- `main`: main title
- `ci.col`: colour for confidence band.

Value

None.

Side Effects

Plots the cumulative periodogram in a square plot.

Note

From package MASS.

Examples

```r
require(graphics)
par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")
cpgram(ldeaths)
```
Cut a Tree into Groups of Data

Description
Cuts a tree, e.g., as resulting from `hclust`, into several groups either by specifying the desired number(s) of groups or the cut height(s).

Usage
```r
cutree(tree, k = NULL, h = NULL)
```

Arguments
- `tree`: a tree as produced by `hclust`. `cutree()` only expects a list with components `merge`, `height`, and `labels`, of appropriate content each.
- `k`: an integer scalar or vector with the desired number of groups
- `h`: numeric scalar or vector with heights where the tree should be cut. At least one of `k` or `h` must be specified, `k` overrides `h` if both are given.

Details
Cutting trees at a given height is only possible for ultrametric trees (with monotone clustering heights).

Value
`cutree` returns a vector with group memberships if `k` or `h` are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of `k` or `h`, respectively (which are also used as column names).

References

See Also
- `hclust`, `dendrogram` for cutting trees themselves.

Examples
```r
hc <- hclust(dist(USArrests))
cutree(hc, k = 1:5) #k = 1 is trivial
cutree(hc, h = 250)

## Compare the 2 and 4 grouping:
g24 <- cutree(hc, k = c(2,4))
table(grp2 = g24[,"2"], grp4 = g24[,"4"])
```
**decompose**

**Classical Seasonal Decomposition by Moving Averages**

**Description**
Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

**Usage**
decompose(x, type = c("additive", "multiplicative"), filter = NULL)

**Arguments**
- **x**: A time series.
- **type**: The type of seasonal component. Can be abbreviated.
- **filter**: A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If NULL, a moving average with symmetric window is performed.

**Details**
The additive model used is:

\[ Y_t = T_t + S_t + e_t \]

The multiplicative model used is:

\[ Y_t = T_t S_t e_t \]

The function first determines the trend component using a moving average (if filter is NULL, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

This only works well if x covers an integer number of complete periods.

**Value**
An object of class "decomposed.ts" with following components:
- **x**: The original series.
- **seasonal**: The seasonal component (i.e., the repeated seasonal figure).
- **figure**: The estimated seasonal figure only.
- **trend**: The trend component.
- **random**: The remainder part.
- **type**: The value of type.

**Note**
The function **stl** provides a much more sophisticated decomposition.

delete.response Modify Terms Objects

Description

delete.response returns a terms object for the same model but with no response variable.
drop.terms removes variables from the right-hand side of the model. There is also a "[.terms" method to perform the same function (with keep.response = TRUE).
reformulate creates a formula from a character vector.

Usage

delete.response(termobj)

reformulate(termlabels, response = NULL, intercept = TRUE)
drop.terms(termobj, dropx = NULL, keep.response = FALSE)
**Arguments**

- `termobj` A terms object
- `termlabels` character vector giving the right-hand side of a model formula. Cannot be zero-length.
- `response` character string, symbol or call giving the left-hand side of a model formula, or NULL.
- `intercept` logical: should the formula have an intercept?
- `dropx` vector of positions of variables to drop from the right-hand side of the model.
- `keep.response` Keep the response in the resulting object?

**Value**

delete.response and drop.terms return a terms object.
reformulate returns a formula.

**See Also**

terms

**Examples**

```r
ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
```

```r
## keep LHS :
reformulate("x*w", ff[[2]])
```

```r
## using non-syntactic names:
reformulate(c("P/E", "% Growth"), response = as.name("+-"))
```

```r
stopifnot(identical(~ y ~ a + b, reformulate(letters[1:3], "y"))
```

---

**Description**

Apply function FUN to each node of a dendrogram recursively. When `y <- dendrapply(x, fn)`, then `y` is a dendrogram of the same graph structure as `x` and for each node, `y.node[j] <- FUN( x.node[j], ...)` (where `y.node[j]` is an (invalid!) notation for the `j`-th node of `y`).

**dendrapply**

Apply a Function to All Nodes of a Dendrogram
Usage

dendrapply(X, FUN, ...)

Arguments

X an object of class "dendrogram".

FUN an R function to be applied to each dendrogram node, typically working on its attributes alone, returning an altered version of the same node.

... potential further arguments passed to FUN.

Value

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually of the form FUN <- function(X) { attributes(X) <- .....; X }, i.e., returning the node with some attributes added or changed.

Note

The implementation is somewhat experimental and suggestions for enhancements (or nice examples of usage) are very welcome. The current implementation is recursive and inefficient for dendrograms with many non-leaves. See the ‘Warning’ in dendrogram.

### dendrogram

**General Tree Structures**

**Description**

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

**Usage**

- `as.dendrogram(object, ...)
  ## S3 method for class 'hclust'
  as.dendrogram(object, hang = -1, check = TRUE, ...)

- `as.dendrogram(object, hang = -1, check = TRUE, ...)
  ## S3 method for class 'dendrogram'
  as.hclust(x, ...)

- `plot(x, type = c("rectangle", "triangle"),
  center = FALSE,
  edge.root = is.leaf(x) || !is.null(attr(x,"edgetext")),
  nodePar = NULL, edgePar = list(),
  leaflab = c("perpendicular", "textlike", "none"),
  dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
  horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

- `cut(x, h, ...)`

- `merge(x, y, ..., height,
  adjust = c("auto", "add.max", "none"))`

- `nobs(object, ...)`

- `print(x, digits, ...)`

- `rev(x)`
## S3 method for class 'dendrogram'
str(object, max.level = NA, digits.d = 3,
    give.attr = FALSE, wid = getOption("width"),
    nest.lev = 0, indent.str = "\"
    last.str = getOption("str.dendrogram.last"), stem = "--",
    ...
)

is.leaf(object)

Arguments

object any R object that can be made into one of class "dendrogram".

x, y object(s) of class "dendrogram".

hang numeric scalar indicating how the height of leaves should be computed from the heights of their parents; see plot.hclust.

check logical indicating if object should be checked for validity. This check is not necessary when x is known to be valid such as when it is the direct result of hclust(). The default is check=TRUE, e.g. for protecting against memory explosion with invalid inputs.

type type of plot.

center logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.

edge.root logical; if true, draw an edge to the root node.

nodePar a list of plotting parameters to use for the nodes (see points) or NULL by default which does not draw symbols at the nodes. The list may contain components named pch, cex, col, xpd, and/or bg each of which can have length two for specifying separate attributes for inner nodes and leaves. Note that the default of pch is 1:2, so you may want to use pch = NA if you specify nodePar.

dLeaf a list of plotting parameters to use for the edge segments and labels (if there's an edgetext). The list may contain components named col, lty and lwd (for the segments), p.col, p.lwd, and p.lty (for the polygon around the text) and t.col for the text color. As with nodePar, each can have length two for differentiating leaves and inner nodes.

leaflab a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default). "textlike" writes text horizontally (in a rectangle), and "none" suppresses leaf labels.

horiz a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.

horiz logical indicating if the dendrogram should be drawn horizontally or not.

frame.plot logical indicating if a box around the plot should be drawn, see plot.default.

height height at which the tree is cut.

height height at which the two dendrograms should be merged. If not specified (or NULL), the default is ten percent larger than the (larger of the) two component heights.

adjust a string determining if the leaf values should be adjusted. The default, "auto", checks if the (first) two dendrograms both start at 1: if they do, code "add.max" is chosen, which adds the maximum of the previous dendrogram leaf values to each leaf of the "next" dendrogram. Specifying adjust to another value skips the check and hence is a tad more efficient.
xlim, ylim optional x- and y-limits of the plot, passed to plot.default. The defaults for these show the full dendrogram.

..., xlab, ylab, xaxt, yaxt graphical parameters, or arguments for other methods.

digits integer specifying the precision for printing, see print.default.

max.level, digits.d, give.attr, wid, nest.lev, indent.str arguments to str, see str.default(). Note that give.attr = FALSE still shows height and members attributes for each node.

last.str, stem strings used for str() specifying how the last branch (at each level) should start and the stem to use for each dendrogram branch. In some environments, using last.str = "/quotesingle.Var" will provide much nicer looking output, than the historical default last.str = "/grave.Var".

Details

The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree z is z[[1]], the second branch of the corresponding subtree is z[[1]][[2]], or shorter z[c(1,2)], etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only members, height and leaf for leaves are compulsory:

members total number of leaves in the branch

height numeric non-negative height at which the node is plotted.

midpoint numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for plot(*, center = FALSE).

label character; the label of the node

x.member for cut()$upper, the number of former members; more generally a substitute for the members component used for ‘horizontal’ (when horiz = FALSE, else ‘vertical’) alignment.

edgetext character; the label for the edge leading to the node

nodePar a named list (of length-1 components) specifying node-specific attributes for points plotting, see the nodePar argument above.

edgePar a named list (of length-1 components) specifying attributes for segments plotting of the edge leading to the node, and drawing of the edgetext if available, see the edgePar argument above.

leaf logical, if TRUE, the node is a leaf of the tree.

cut.dendrogram() returns a list with components $upper and $lower, the first is a truncated version of the original tree, also of class dendrogram, the latter a list with the branches obtained from cutting the tree, each a dendrogram.

There are [[, print, and str methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class, i.e., returns a dendrogram even if only a leaf. On the other hand, [] (single bracket) extraction returns the underlying list structure.

Objects of class "hclust" can be converted to class "dendrogram" using method as.dendrogram(), and since R 2.13.0, there is also a as.hclust() method as an inverse.

rev.dendrogram simply returns the dendrogram x with reversed nodes, see also reorder.dendrogram.

The merge(x, y, ...) method merges two or more dendrograms into a new one which has x and y (and optional further arguments) as branches. Note that before R 3.1.2, adjust = "none" was used implicitly, which is invalid when, e.g., the dendrograms are from as.dendrogram(hclust(...)).
\texttt{nobs(object)} returns the total number of leaves (the members attribute, see above).
\texttt{is.leaf(object)} returns logical indicating if object is a leaf (the most simple dendrogram).
\texttt{plotNode()} and \texttt{plotNodeLimit()} are helper functions.

**Warning**

Some operations on dendrograms such as \texttt{merge()} make use of recursion. For deep trees it may be necessary to increase \texttt{options("expressions")}: if you do, you are likely to need to set the C stack size (\texttt{Cstack_info()["size"]}) larger than the default where possible.

**Note**

\texttt{plot()}: When using \texttt{type = "triangle", center = TRUE} often looks better.
\texttt{str(d)}: If you really want to see the internal structure, use \texttt{str(unclass(d))} instead.

**See Also**

dendrapply for applying a function to each node. \texttt{order.dendrogram} and \texttt{reorder.dendrogram}; further, the \texttt{labels} method.

**Examples**

\begin{verbatim}
require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1) # "str()" method
str(dend1, max = 2, last.str = ",") # only the first two sub-levels

oo <- options(str.dendrogram.last = ").") # yet another possibility
str(dend1, max = 2) # only the first two sub-levels
options(oo) # .. resetting them

op <- par(mfrow = c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar = list(pch = c(1,NA), cex = 0.8, lab.cex = 0.8),
   type = "t", center = TRUE)
plot(dend1, edgePar = list(col = 1:2, lty = 2:3),
   dLeaf = 1, edge.root = TRUE)
plot(dend1, nodePar = list(pch = 2:1, cex = .4*2:1, col = 2:3),
   horiz = TRUE)

## simple test for \texttt{as.hclust()} as the inverse of \texttt{as.dendrogram()}:
stopifnot(identical(as.hclust(dend1)[1:4], hc[1:4]))

dend2 <- cut(dend1, h = 70)
plot(dend2$upper)
## leaves are wrong horizontally:
plot(dend2$upper, nodePar = list(pch = c(1,7), col = 2:1))

## dend2$lower is NOT a dendrogram, but a list of .. :
plot(dend2$lower[[3]], nodePar = list(col = 4), horiz = TRUE, type = "t")

## "inner" and "leaf" edges in different type & color:
plot(dend2$lower[[2]], nodePar = list(col = 1),
   edgePar = list(lty = 1:2, col = 2:1), edge.root = TRUE)

par(op)
\end{verbatim}
density <- dend2$lower[[2]][[2]][[1]]
stopifnot(identical(d3, dend2$lower[[2]][[c(2,1)]]))
str(d3, last.str = "")

## to peek at the inner structure "if you must", use '[...]' indexing :
str(d3[2][[1]]) ## or the full
str(d3)

## merge() to join dendrograms:
(d13 <- merge(dend2$lower[[1]], dend2$lower[[3]]))
## merge() all parts back (using default 'height' instead of original one):
den.1 <- Reduce(merge, dend2$lower)
## or merge() all four parts at same height --> 4 branches (!)
d. <- merge(dend2$lower[[1]], dend2$lower[[2]], dend2$lower[[3]],
           dend2$lower[[4]])
## (with a warning) or the same using do.call :
stopifnot(identical(d., do.call(merge, dend2$lower)))
plot(d., main = "merge(d1, d2, d3, d4) |-> dendrogram with a 4-split")

## "Zoom" in to the first dendrogram :
plot(dend1, xlim = c(1,20), ylim = c(1,50))

nP <- list(col = 3:2, cex = c(2.0, 0.75), pch = 21:22,
           bg = c("light blue", "pink"),
           lab.cex = 0.75, lab.col = "tomato")
plot(d3, nodePar= nP, edgePar = list(col = "gray", lwd = 2), horiz = TRUE)

addE <- function(n) {
  if(!is.leaf(n)) {
    attr(n, "edgePar") <- list(p.col = "plum")
    attr(n, "edgetext") <- paste(attr(n, "members"), "members")
  }
  n
}
d3e <- dendrapply(d3, addE)
plot(d3e, nodePar = nP)
plot(d3e, nodePar = nP, leaflab = "textlike")

---

density

Kernel Density Estimation

Description

The (S3) generic function density computes kernel density estimates. Its default method does so
with the given kernel and bandwidth for univariate observations.

Usage

density(x, ...)
## Default S3 method:
density(x, bw = "nrd0", adjust = 1,
density

kernel = c("gaussian", "epanechnikov", "rectangular",
"triangular", "biweight",
"cosine", "optcosine"),
weights = NULL, window = kernel, width,
give.Rkern = FALSE,
n = 512, from, to, cut = 3, na.rm = FALSE, ...)

Arguments

x the data from which the estimate is to be computed. For the default method a numeric vector: long vectors are not supported.
bw the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below, and from S-PLUS.) bw can also be a character string giving a rule to choose the bandwidth. See bw.nrd. The default, "nrd0", has remained the default for historical and compatibility reasons, rather than as a general recommendation, where e.g., "SJ" would rather fit, see also Venables and Ripley (2002). The specified (or computed) value of bw is multiplied by adjust.
adjust the bandwidth used is actually adjust*bw. This makes it easy to specify values like ‘half the default’ bandwidth.
kernel, window a character string giving the smoothing kernel to be used. This must partially match one of "gaussian", "rectangular", "triangular", "epanechnikov", "biweight", "cosine" or "optcosine", with default "gaussian", and may be abbreviated to a unique prefix (single letter). "cosine" is smoother than "optcosine", which is the usual ‘cosine’ kernel in the literature and almost MSE-efficient. However, "cosine" is the version used by S.
weights numeric vector of non-negative observation weights, hence of same length as x. The default NULL is equivalent to weights = rep(1/nx, nx) where nx is the length of (the finite entries of) x[].
width this exists for compatibility with S; if given, and bw is not, will set bw to width if this is a character string, or to a kernel-dependent multiple of width if this is numeric.
give.Rkern logical; if true, no density is estimated, and the ‘canonical bandwidth’ of the chosen kernel is returned instead.
n the number of equally spaced points at which the density is to be estimated. When n > 512, it is rounded up to a power of 2 during the calculations (as fft is used) and the final result is interpolated by approx. So it almost always makes sense to specify n as a power of two.
from,to the left and right-most points of the grid at which the density is to be estimated; the defaults are cut * bw outside of range(x).
cut by default, the values of from and to are cut bandwidths beyond the extremes of the data. This allows the estimated density to drop to approximately zero at the extremes.
na.rm logical; if TRUE, missing values are removed from x. If FALSE any missing values cause an error.
... further arguments for (non-default) methods.
**density**

**Details**

The algorithm used in `density.default` disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by $\sigma^2_K = \int t^2 K(t) dt$ which is always $= 1$ for our kernels (and hence the bandwidth $bw$ is the standard deviation of the kernel) and $R(K) = \int K^2(t) dt$.

MSE-equivalent bandwidths (for different kernels) are proportional to $\sigma_K R(K)$ which is scale invariant and for our kernels equal to $R(K)$. This value is returned when `give.Rkern = TRUE`. See the examples for using exact equivalent bandwidths.

Infinite values in `x` are assumed to correspond to a point mass at $+/-\text{Inf}$ and the density estimate is of the sub-density on $(-\text{Inf}, +\text{Inf})$.

**Value**

If `give.Rkern` is true, the number $R(K)$, otherwise an object with class "density" whose underlying structure is a list containing the following components.

- `x` the `n` coordinates of the points where the density is estimated.
- `y` the estimated density values. These will be non-negative, but can be zero.
- `bw` the bandwidth used.
- `n` the sample size after elimination of missing values.
- `call` the call which produced the result.
- `data.name` the deparsed name of the `x` argument.
- `has.na` logical, for compatibility (always `FALSE`).

The `print` method reports `summary` values on the `x` and `y` components.

legend(55, 0.035, legend = kernels, col = seq(kernels), lty = 1)

---

**deriv**  
**Symbolic and Algorithmic Derivatives of Simple Expressions**

**Description**
Compute derivatives of simple expressions, symbolically and algorithmically.

**Usage**

```
D (expr, name)
deriv(expr, ...)
deriv3(expr, ...)
```

## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = FALSE, ...)

## S3 method for class 'formula'
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = FALSE, ...)

## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = TRUE, ...)

## S3 method for class 'formula'
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
hessian = TRUE, ...)
Arguments

expr         a **expression** or **call** or (except D) a formula with no lhs.
name, namevec character vector, giving the variable names (only one for D(\(\theta\))) with respect to which derivatives will be computed.
function.arg if specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names namevec should be used.
tag  character; the prefix to be used for the locally created variables in result.
hessian     a logical value indicating whether the second derivatives should be calculated and incorporated in the return value.
... arguments to be passed to or from methods.

Details

D is modelled after its S namesake for taking simple symbolic derivatives.

deriv is a **generic** function with a default and a **formula** method. It returns a **call** for computing the expr and its (partial) derivatives, simultaneously. It uses so-called **algorithmic derivatives**. If function.arg is a function, its arguments can have default values, see the fx example below.

Currently, deriv.formula just calls deriv.default after extracting the expression to the right of ~.
deriv3 and its methods are equivalent to deriv and its methods except that hessian defaults to TRUE for deriv3.

The internal code knows about the arithmetic operators +, -, *, / and ^, and the single-variable functions exp, log, sin, cos, tan, sinh, cosh, sqrt, pnorm, dnorm, asin, acos, atan, gamma, lgamma, digamma and trigamma, as well as psigamma for one or two arguments (but derivative only with respect to the first). (Note that only the standard normal distribution is considered.)

Since R 3.4.0, the single-variable functions log1p, expm1, log2, log10, cospi, sinpi, tanpi, factorial, and lfactorial are supported as well.

Value

D returns a call and therefore can easily be iterated for higher derivatives.
deriv and deriv3 normally return an **expression** object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If hessian is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.

If function.arg is not NULL, deriv and deriv3 return a function with those arguments rather than an expression.

**nls** and **optim** for numeric minimization which could make use of derivatives,
Examples

```r
## formula argument:
dx2x <- deriv(~ x^2, "x")
dx2x
## Not run: expression(
  .value <- x^2
  .grad <- array(0, c(length(.value), 1), list(NULL, c("x")))
  .grad[, "x"] <- 2 * x
  attr(.value, "gradient") <- .grad
  .value
)
## End(Not run)
mode(dx2x)
x <- -1:2
eval(dx2x)

## Something 'tougher':
trig.exp <- expression(sin(cos(x + y^2)))
(D.sc <- D(trig.exp, "x")
all.equal(D(trig.exp[[1]], "x"), D.sc)

(dxy <- deriv(trig.exp, c("x", "y"))
y <- 1
eval(dxy)
eval(D.sc)

## function returned:
deriv(y ~ sin(cos(x) * y)), c("x","y"), func = TRUE)

## function with defaulted arguments:
(fx <- deriv(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
  function(b0, b1, th, x = 1:7){})
fx(2, 3, 4)

## First derivative
D(expression(x^2), "x")
stopifnot(D(as.name("x"), "x") == 1)

## Higher derivatives
deriv3(y ~ b0 + b1 * 2^(-x/th), c("b0", "b1", "th"),
  c("b0", "b1", "th", "x"))

## Higher derivatives:
DD <- function(expr, name, order = 1) {
  if(order < 1) stop("order" must be >= 1")
  if(order == 1) D(expr, name)
  else DD(D(expr, name), name, order - 1)
}
DD(expression(sin(x^2)), "x", 3)
## showing the limits of the internal "simplify()" :
## Not run:
-sin(x^2) * (2 * x) * 2 + ((cos(x^2) * (2 * x) * (2 * x) + sin(x^2) * 2) * (2 * x) + sin(x^2) * (2 * x) * 2)
## End(Not run)
```
## New (R 3.4.0, 2017):

```
D(quote(log1p(x^2)), "x")  ## log1p(x) = log(1 + x)
stopifnot(identical(
    D(quote(log1p(x^2)), "x"),
    D(quote(log(1+x^2)), "x"))

    D(quote(expm1(x^2)), "x") -> Dex1,
    D(quote(exp(x^2)-1), "x")),
    identical(Dex1, quote(exp(x^2) * (2 * x))))
D(quote(sinpi(x^2)), "x")  ## sinpi(x) = sin(pi*x)
D(quote(cospi(x^2)), "x")  ## cospi(x) = cos(pi*x)
D(quote(tanpi(x^2)), "x")  ## tanpi(x) = tan(pi*x)
```

stopifnot(identical(D(quote(log2 (x^2)), "x"),
    quote(2 * x/(x^2 * log(2)))),
    identical(D(quote(log10(x^2)), "x"),
    quote(2 * x/(x^2 * log(10)))))

---

### deviance

**Model Deviance**

#### Description

Returns the deviance of a fitted model object.

#### Usage

```
deviance(object, ...)```

#### Arguments

- **object**: an object for which the deviance is desired.
- **...**: additional optional argument.

#### Details

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

#### Value

The value of the deviance extracted from the object object.

#### References

#### See Also

- `df.residual`, `extractAIC`, `glm`, `lm`
**df.residual**

**Residual Degrees-of-Freedom**

**Description**

Returns the residual degrees-of-freedom extracted from a fitted model object.

**Usage**

```r
df.residual(object, ...)
```

**Arguments**

- `object`: an object for which the degrees-of-freedom are desired.
- `...`: additional optional arguments.

**Details**

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the `df.residual` component.

**Value**

The value of the residual degrees-of-freedom extracted from the object `x`.

**See Also**

- `deviance`, `glm`, `lm`.

---

**diffinv**

**Discrete Integration: Inverse of Differencing**

**Description**

Computes the inverse function of the lagged differences function `diff`.

**Usage**

```r
diffinv(x, ...)  
```

## Default S3 method:
```
diffinv(x, lag = 1, differences = 1, xi, ...)  
```

## S3 method for class `ts`
```
diffinv(x, lag = 1, differences = 1, xi, ...)
```
Arguments

- **x**: a numeric vector, matrix, or time series.
- **lag**: a scalar lag parameter.
- **differences**: an integer representing the order of the difference.
- **xi**: a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
- ...: arguments passed to or from other methods.

Details

diffinv is a generic function with methods for class "ts" and default for vectors and matrices. Missing values are not handled.

Value

A numeric vector, matrix, or time series (the latter for the "ts" method) representing the discrete integral of *x*.

Examples

```r
s <- 1:10
d <- diff(s)
diffinv(d, xi = 1)
```

---

**dist**

**Distance Matrix Computation**

Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

Usage

```r
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)
as.dist(m, diag = FALSE, upper = FALSE)
## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)
## S3 method for class 'dist'
print(x, diag = NULL, upper = NULL,
```
## S3 method for class 'dist'

\[
\text{as.matrix}(x, \ldots)
\]

### Arguments

- **x**: A numeric matrix, data frame or "dist" object.
- **method**: The distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
- **diag**: Logical value indicating whether the diagonal of the distance matrix should be printed by `print.dist`.
- **upper**: Logical value indicating whether the upper triangle of the distance matrix should be printed by `print.dist`.
- **p**: The power of the Minkowski distance.
- **m**: An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using `as.matrix()`. (Only the lower triangle of the matrix is used, the rest is ignored).
- **digits, justify**
  - Passed to `format` inside of `print()`.
- **right, ...**
  - Further arguments, passed to other methods.

### Details

Available distance measures are (written for two vectors \(x\) and \(y\)):

- **euclidean**: Usual distance between the two vectors (2 norm aka \(L_2\)). \(\sqrt{\sum_i (x_i - y_i)^2}\).
- **maximum**: Maximum distance between two components of \(x\) and \(y\) (supremum norm)
- **manhattan**: Absolute distance between the two vectors (1 norm aka \(L_1\)).
- **canberra**: \(\sum_i |x_i - y_i| / (|x_i| + |y_i|)\). Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.
  - This is intended for non-negative values (e.g., counts), in which case the denominator can be written in various equivalent ways; Originally, R used \(x_i + y_i\), then from 1998 to 2017, \(|x_i + y_i|\), and then the correct \(|x_i| + |y_i|\).
- **binary**: (aka asymmetric binary): The vectors are regarded as binary bits, so non-zero elements are 'on' and zero elements are 'off'. The distance is the proportion of bits in which only one is on amongst those in which at least one is on.
- **minkowski**: The \(p\) norm, the \(p\)th root of the sum of the \(p\)th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when \(\text{Inf}\) values are involved, all pairs of values are excluded when their contribution to the distance gave \(\text{NaN}\) or \(\text{NA}\). If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is \(\text{NA}\).
The "dist" method of as.matrix() and as.dist() can be used for conversion between objects of class "dist" and conventional distance matrices.

as.dist() is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using as.matrix(). Support for classes representing distances (also known as dissimilarities) can be added by providing an as.matrix() or, more directly, an as.dist method for such a class.

Value

dist returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say do. If n is the number of observations, i.e., n <- attr(do, "Size"), then for i < j ≤ n, the dissimilarity between (row) i and j is do[n*(i-1) - i*(i-1)/2 + j-i]. The length of the vector is n \* (n - 1)/2, i.e., of order n^2.

The object has the following attributes (besides "class" equal to "dist"):

- **Size**: integer, the number of observations in the dataset.
- **Labels**: optionally, contains the labels, if any, of the observations of the dataset.
- **Diag, Upper**: logicals corresponding to the arguments diag and upper above, specifying how the object should be printed.
- **call**: optionally, the call used to create the object.
- **method**: optionally, the distance method used; resulting from dist(), the (match.arg()ed) method argument.

daisy in the cluster package with more possibilities in the case of mixed (continuous / categorical) variables. hclust.

Examples

```r
require(graphics)
x <- matrix(rnorm(100), nrow = 5)
dist(x)
dist(x, diag = TRUE)
dist(x, upper = TRUE)
m <- as.matrix(dist(x))
d <- as.dist(m)
stopifnot(d == dist(x))

## Use correlations between variables "as distance"

dd <- as.dist((1 - cor(USJudgeRatings))/2)
round(1000 * dd) # (prints more nicely)
```
plot(hclust(dd)) # to see a dendrogram of clustered variables

## example of binary and canberra distances.
x <- c(0, 0, 1, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x, y), method = "binary")
## answer 0.4 = 2/5

dist(rbind(x, y), method = "canberra")
## answer 2 * (6/5)

## To find the names
labels(eurodist)

## Examples involving "Inf" :
## 1)
x[6] <- Inf
(m2 <- rbind(x, y))
dist(m2, method = "binary") # warning, answer 0.5 = 2/4
## These all give "Inf":
stopifnot(Inf == dist(m2, method = "euclidean"),
          Inf == dist(m2, method = "maximum"),
          Inf == dist(m2, method = "manhattan")
## "Inf" is same as very large number:
x1 <- x; x1[6] <- 1e100
stopifnot(dist(cbind(x, y), method = "canberra") ==
          print(dist(cbind(x1, y), method = "canberra")))

## 2)
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x, y), method = "binary") # warning; 0.5
dist(rbind(x, y), method = "canberra") # 3
dist(rbind(x, y), method = "maximum") # 1
dist(rbind(x, y), method = "manhattan") # 2.4

**Distributions**

**Distributions in the stats package**

**Description**

Density, cumulative distribution function, quantile function and random variate generation for many standard probability distributions are available in the `stats` package.

**Details**

The functions for the density/mass function, cumulative distribution function, quantile function and random variate generation are named in the form `dxxx`, `pxxx`, `qxxx` and `rxxx` respectively.

For the beta distribution see `dbeta`.
For the binomial (including Bernoulli) distribution see `dbinom`.
For the Cauchy distribution see `dcauchy`.
For the chi-squared distribution see `dchisq`.
For the exponential distribution see `dexp`.
For the F distribution see `df`.
For the gamma distribution see `dgamma`.
For the geometric distribution see `dgeom`. (This is also a special case of the negative binomial.)
For the hypergeometric distribution see `dhyper`.
For the log-normal distribution see `dlnorm`.
For the multinomial distribution see `dmultinom`.
For the negative binomial distribution see `dnbinom`.
For the normal distribution see `dnorm`.
For the Poisson distribution see `dpois`.
For the Student’s t distribution see `dt`.
For the uniform distribution see `dunif`.
For the Weibull distribution see `dweibull`.
For less common distributions of test statistics see `pbirthday`, `dsignrank`, `ptukey` and `d wilcox` (and see the ‘See Also’ section of `cor.test`).

See Also

`RNG` about random number generation in R.

The CRAN task view on distributions, [https://CRAN.R-project.org/view=Distributions](https://CRAN.R-project.org/view=Distributions), mentioning several CRAN packages for additional distributions.

dummy.coef

Extract Coefficients in Original Coding

dummy.coef

Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

Usage

dummy.coef(object, ...)

## S3 method for class `lm`
dummy.coef(object, use.na = FALSE, ...)

## S3 method for class `aovlist`
dummy.coef(object, use.na = FALSE, ...)

Arguments

- **object**: a linear model fit.
- **use.na**: logical flag for coefficients in a singular model. If `use.na` is true, undetermined coefficients will be missing; if false they will get one possible value.
- **...**: arguments passed to or from other methods.
ecdf

Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for \texttt{contr.helmert} or \texttt{contr.sum}) will be respected. There will be little point in using \texttt{dummy.coef} for \texttt{contr.treatment} contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as \texttt{poly(x, 2)}. However, it is adequate for its main purpose, \texttt{aov} models.

Value

A list giving for each term the values of the coefficients. For a multistratum \texttt{aov} model, such a list for each stratum.

Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

See Also

\texttt{aov}, \texttt{model.tables}

Examples

\begin{verbatim}
options(contrasts = c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)
\end{verbatim}

ecdf

\textit{Empirical Cumulative Distribution Function}

Description

Compute an empirical cumulative distribution function, with several methods for plotting, printing and computing with such an \texttt{ecdf} object.

Usage

\begin{verbatim}
ecdf(x)
\end{verbatim}

\begin{verbatim}
## S3 method for class 'ecdf'
plot(x, ..., ylab="Fn(x)", verticals = FALSE,
     col.01line = "gray70", pch = 19)
\end{verbatim}

\begin{verbatim}
## S3 method for class 'ecdf'
\end{verbatim}
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'ecdf'
summary(object, ...)
## S3 method for class 'ecdf'
quantile(x, ...)

Arguments

x, object numeric vector of the observations for ecdf; for the methods, an object inheriting from class "ecdf".
...
arguments to be passed to subsequent methods, e.g., plot.stepfun for the plot method.
ylab label for the y-axis.
verticals see plot.stepfun.
col.01line numeric or character specifying the color of the horizontal lines at y = 0 and 1, see colors.
pch plotting character.
digits number of significant digits to use, see print.

Details

The e.c.d.f. (empirical cumulative distribution function) \( F_n \) is a step function with jumps \( i/n \) at observation values, where \( i \) is the number of tied observations at that value. Missing values are ignored.

For observations \( x = (x_1, x_2, \ldots, x_n) \), \( F_n \) is the fraction of observations less or equal to \( t \), i.e.,

\[
F_n(t) = \frac{\# \{ x_i \leq t \}}{n} = \frac{1}{n} \sum_{i=1}^{n} 1[x_i \leq t].
\]

The function plot.ecdf which implements the plot method for ecdf objects, is implemented via a call to plot.stepfun; see its documentation.

Value

For ecdf, a function of class "ecdf", inheriting from the "stepfun" class, and hence inheriting a knots() method.

For the summary method, a summary of the knots of object with a "header" attribute.

The quantile(obj, ...) method computes the same quantiles as quantile(x, ...) would where x is the original sample.

Note

The objects of class "ecdf" are not intended to be used for permanent storage and may change structure between versions of \( R \) (and did at \( R \) 3.0.0). They can usually be re-created by

\[
eval(attr(old_obj, "call"), environment(old_obj))
\]

since the data used is stored as part of the object’s environment.

require(graphics)
op <- par(mfrow = c(3, 1), mgp = c(1.5, 0.8, 0), mar = .1+c(3,3,2,1))
F10 <- ecdf(rnorm(10))
summary(F10)

plot(F10)
plot(F10, verticals = TRUE, do.points = FALSE)

plot(Fn12, lwd = 2); mtext("lwd = 2", adj = 1)
xx <- unique(sort(c(seq(-3, 2, length = 201), knots(Fn12))))
lines(xx, Fn12(xx), col = "blue")
abline(v = knots(Fn12), lty = 2, col = "gray70")

plot(xx, Fn12(xx), type = "o", cex = .1) #- plot.default (ugly)
plot(Fn12, col.hor = "red", add = TRUE) #- plot method
abline(v = knots(Fn12), lty = 2, col = "gray70")

## luxury plot
plot(Fn12, verticals = TRUE, col.points = "blue",
     col.hor = "red", col.vert = "bisque")
### Description

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

#### Usage

```r
eff.aovlist(aovlist)
```

#### Arguments

- `aovlist` The result of a call to `aov` with an `Error` term.

#### Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in `model.tables.aovlist` and `se.contrast.aovlist`.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g., treatment contrasts or an unbalanced design) are detected.

#### Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

#### References

#### See Also

`aov`, `model.tables.aovlist`, `se.contrast.aovlist`
Examples

## An example from Yates (1932),
## a 2^3 design in 2 blocks replicated 4 times

Block <- gl(8, 4)
A <- factor(c(0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1,0,1))
B <- factor(c(0,0,1,1,0,0,1,1,0,1,0,1,1,0,1,0,0,0,1,1,0,0,1,1,0,0,1,1,0,0,1,1,0,0,1,1,0,0,1,1,0,0,1,1,0,0,1,1,0))
C <- factor(c(0,1,1,0,1,0,1,1,0,1,0,1,1,0,1,0,1,0,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0,1,1,0))
aovdat <- data.frame(Block, A, B, C, Yield)
old <- getOption("contrasts")
options(contrasts = c("contr.helmert", "contr.poly"))
(fit <- aov(Yield ~ A*B*C + Error(Block), data = aovdat))
eff.aovlist(fit)
options(contrasts = old)

---

## Description

`effects` returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

## Usage

```r
effects(object, ...)  
```

## S3 method for class 'lm'

```r
effects(object, set.sign = FALSE, ...)  
```

## Arguments

- `object` (an R object; typically, the result of a model fitting function such as `lm`.
- `set.sign` (logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.

## Details

For a linear model fitted by `lm` or `aov`, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first \( r \) (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.
Value

A (named) numeric vector of the same length as `residuals`, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first $r$ rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

References

See Also

`coef`

Examples

```r
y <- c(1:3, 7, 5)
x <- c(1:3, 6:7)
( ee <- effects(lm(y ~ x)) )
c( round(ee - effects(lm(y+10 ~ I(x-3.8))), 3) )
# just the first is different
```

### embed

**Embedding a Time Series**

**Description**

Embeds the time series $x$ into a low-dimensional Euclidean space.

**Usage**

```r
eMBED (x, dimension = 1)
```

**Arguments**

- `x`: a numeric vector, matrix, or time series.
- `dimension`: a scalar representing the embedding dimension.

**Details**

Each row of the resulting matrix consists of sequences $x[t]$, $x[t-1]$, ..., $x[t\text{-}dimension+1]$, where $t$ is the original index of $x$. If $x$ is a matrix, i.e., $x$ contains more than one variable, then $x[t]$ consists of the $t$th observation on each variable.

**Value**

A matrix containing the embedded time series $x$.

**Author(s)**

A. Trapletti, B.D. Ripley
Examples

```r
x <- 1:10
embed(x, 3)
```

**Description**

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same `na.action` and `subset` arguments are applied and allows, for example, `x` to be recovered for a model using `sin(x)` as a predictor.

**Usage**

```r
expand.model.frame(model, extras, 
  envir = environment(formula(model)), 
  na.expand = FALSE)
```

**Arguments**

- `model` a fitted model
- `extras` one-sided formula or vector of character strings describing new variables to be added
- `envir` an environment to evaluate things in
- `na.expand` logical; see below

**Details**

If `na.expand = FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand = TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

**Value**

A data frame.

**See Also**

`model.frame`, `predict`

**Examples**

```r
model <- lm(log(Volume) ~ log(Girth) + log(Height), data = trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x = 1:5, y = rnorm(5), z = c(1,2,NA,4,5))
model <- glm(y ~ x, data = dd, subset = 1:4, na.action = na.omit)
expand.model.frame(model, "z", na.expand = FALSE) # = default
expand.model.frame(model, "z", na.expand = TRUE)
```
The Exponential Distribution

Description

Density, distribution function, quantile function and random generation for the exponential distribution with rate rate (i.e., mean 1/rate).

Usage

dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)  
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)

Arguments

x, q
vector of quantiles.

p
vector of probabilities.

n
number of observations. If length(n) > 1, the length is taken to be the number required.

rate
vector of rates.

log, log.p
logical; if TRUE, probabilities p are given as log(p).

lower.tail
logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

If rate is not specified, it assumes the default value of 1.

The exponential distribution with rate λ has density

$$f(x) = \lambda e^{-\lambda x}$$

for $$x \geq 0$$.

Value

dexp gives the density, pexp gives the distribution function, qexp gives the quantile function, and rexp generates random deviates.

The length of the result is determined by n for rexp, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard $$H(t) = -\log(1 - F(t))$$ is -pexp(t, r, lower = FALSE, log = TRUE).
Source

dexp, pexp and qexp are all calculated from numerically stable versions of the definitions.

rsunif <- function(n) { n1 <- n+1
cE <- cumsum(rexp(n1)); cE[seq_len(n)]/cE[n1] }
plot(rsunif(1000), ylim=0:1, pch=".")
abline(0,1/(1000+1), col=adjustcolor(1, 0.5))

extractAIC

*Extract AIC from a Fitted Model*

Description

Computes the (generalized) Akaike *An Information Criterion* for a fitted parametric model.

Usage

extractAIC(fit, scale, k = 2, ...)

Arguments

fit fitted model, usually the result of a fitter like lm.

scale optional numeric specifying the scale parameter of the model, see scale in step. Currently only used in the "lm" method, where scale specifies the estimate of the error variance, and scale = 0 indicates that it is to be estimated by maximum likelihood.

k numeric specifying the ‘weight’ of the equivalent degrees of freedom (≡ edf) part in the AIC formula.

... further arguments (currently unused in base R).
Details

This is a generic function, with methods in base R for classes "aov", "glm" and "lm" as well as for "negbin" (package MASS) and "coxph" and "survreg" (package survival).

The criterion used is

\[ AIC = -2 \log L + k \times \text{edf}, \]

where \( L \) is the likelihood and \( \text{edf} \) the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of \( \text{fit} \).

For linear models with unknown scale (i.e., for \textit{lm} and \textit{aov}), \(-2 \log L\) is computed from the \textit{deviance} and uses a different additive constant to \texttt{logLik} and hence \texttt{AIC}. If \( \text{RSS} \) denotes the (weighted) residual sum of squares then \texttt{extractAIC} uses for \(-2 \log L\) the formulae \( \text{RSS}/s - n \) (corresponding to Mallows’ \( C_p \)) in the case of known scale \( s \) and \( n \log(\text{RSS}/n) \) for unknown scale. \texttt{AIC} only handles unknown scale and uses the formula \( n \log(\text{RSS}/n) + n + n \log 2\pi - \sum \log w \) where \( w \) are the weights. Further \texttt{AIC} counts the scale estimation as a parameter in the \text{edf} and \texttt{extractAIC} does not.

For \textit{glm} fits the family’s \texttt{aic()} function is used to compute the AIC; see the note under \texttt{logLik} about the assumptions this makes.

\( k = 2 \) corresponds to the traditional AIC, using \( k = \log(n) \) provides the BIC (Bayesian IC) instead.

Note that the methods for this function may differ in their assumptions from those of methods for \texttt{AIC} (usually via a method for \texttt{logLik}). We have already mentioned the case of "lm" models with estimated scale, and there are similar issues in the "glm" and "negbin" methods where the dispersion parameter may or may not be taken as ‘free’. This is immaterial as \texttt{extractAIC} is only used to compare models of the same class (where only differences in AIC values are considered).

Value

A numeric vector of length 2, with first and second elements giving

- \texttt{edf}: the ‘equivalent degrees of freedom’ for the fitted model \texttt{fit}.
- \texttt{AIC}: the (generalized) Akaike Information Criterion for \texttt{fit}.

Note

This function is used in \texttt{add1}, \texttt{drop1} and \texttt{step} and the similar functions in package \texttt{MASS} from which it was adopted.

Author(s)

B. D. Ripley

```

**factanal**  

**Factor Analysis**

**Description**

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

**Usage**

```r
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
subset, na.action, start = NULL,
scores = c("none", "regression", "Bartlett"),
rotation = "varimax", control = NULL, ...)
```

**Arguments**

- **x**: A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
- **factors**: The number of factors to be fitted.
- **data**: An optional data frame (or similar: see `model.frame`), used only if `x` is a formula. By default the variables are taken from `environment(formula)`.
- **covmat**: A covariance matrix, or a covariance list as returned by `cov.wt`. Of course, correlation matrices are covariance matrices.
- **n.obs**: The number of observations, used if `covmat` is a covariance matrix.
- **subset**: A specification of the cases to be used, if `x` is used as a matrix or formula.
- **na.action**: The `na.action` to be used if `x` is used as a formula.
- **start**: `NULL` or a matrix of starting values, each column giving an initial set of uniquenesses.
- **scores**: Type of scores to produce, if any. The default is none, "regression" gives Thompson’s scores, "Bartlett" given Bartlett’s weighted least-squares scores. Partial matching allows these names to be abbreviated.
- **rotation**: character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component `loadings` giving the rotated loadings, or just the rotated loadings.
- **control**: A list of control values,
  - `nstart`: The number of starting values to be tried if `start` = `NULL`. Default 1.
  - `lower`: The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005.
  - `opt`: A list of control values to be passed to `optim`'s `control` argument.
  - `rotate`: a list of additional arguments for the rotation function.
  - `...`: Components of `control` can also be supplied as named arguments to `factanal`. 

...
The factor analysis model is

\[ x = \Lambda f + e \]

for a \( p \)-element vector \( x \), a \( p \times k \) matrix \( \Lambda \) of loadings, a \( k \)-element vector \( f \) of scores and a \( p \)-element vector \( e \) of errors. None of the components other than \( x \) is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances \( \Psi \), the uniquenesses. It is also common to scale the observed variables to unit variance, and done in this function.

Thus factor analysis is in essence a model for the correlation matrix of \( x \),

\[ \Sigma = \Lambda \Lambda' + \Psi \]

There is still some indeterminacy in the model for it is unchanged if \( \Lambda \) is replaced by \( G \Lambda \) for any orthogonal matrix \( G \). Such matrices \( G \) are known as rotations (although the term is applied also to non-orthogonal invertible matrices).

If \( \text{covmat} \) is supplied it is used. Otherwise \( x \) is used if it is a matrix, or a formula \( x \) is used with \( \text{data} \) to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance matrix is found or calculated from \( x \), it is converted to a correlation matrix for analysis. The correlation matrix is returned as component correlation of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in \( \text{start} \) are tried in turn and the best fit obtained is used. If \( \text{start} = \text{NULL} \) then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then \( \text{control}\$nstart - 1 \) other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in \([0, 1]\), but near-zero values are problematical, and the optimization is done with a lower bound of \( \text{control}\$lower \), default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores \( f \). Thomson’s method regresses (in the population) the unknown \( f \) on \( x \) to yield

\[ \hat{f} = \Lambda \Sigma^{-1} x \]

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett’s method minimizes the sum of squares of standardized errors over the choice of \( f \), given (the fitted) \( \Lambda \).

If \( x \) is a formula then the standard \( \text{NA} \)-handling is applied to the scores (if requested): see \text{napredict}.

The \text{print} method (documented under \text{loadings}) follows the factor analysis convention of drawing attention to the patterns of the results, so the default precision is three decimal places, and small loadings are suppressed.

**Value**

An object of class "factanal" with components

- **loadings**: A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive. This is of class "loadings": see \text{loadings} for its \text{print} method.

- **uniquenesses**: The uniquenesses computed.
correlation  The correlation matrix used.
criteria     The results of the optimization: the value of the criterion (a linear function of
             the negative log-likelihood) and information on the iterations used.
factors      The argument factors.
dof          The number of degrees of freedom of the factor analysis model.
method       The method: always "mle".
rotmat       The rotation matrix if relevant.
scores       If requested, a matrix of scores. napredict is applied to handle the treatment
             of values omitted by the na.action.
n.obs        The number of observations if available, or NA.
call         The matched call.
na.action    If relevant.
STATISTIC,  PVAL  The significance-test statistic and P value, if it can be computed.

Note
There are so many variations on factor analysis that it is hard to compare output from different
programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other
examples we compared had less good fits than produced by this function. In particular, solutions
which are ‘Heywood cases’ (with one or more uniquenesses essentially zero) are much more common
than most texts and some other programs would lead one to believe.

---

**factor.scope**

*Compute Allowed Changes in Adding to or Dropping from a Formula*

**Description**

`add.scope` and `drop.scope` compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

**Usage**

```r
add.scope(terms1, terms2)
drop.scope(terms1, terms2)

factor.scope(factor, scope)
```

**Arguments**

- `terms1`: the terms or formula for the base model.
- `terms2`: the terms or formula for the upper (`add.scope`) or lower (`drop.scope`) scope. If missing for `drop.scope` it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.
- `factor`: the "factor" attribute of the terms of the base object.
- `scope`: a list with one or both components `drop` and `add` giving the "factor" attribute of the lower and upper scopes respectively.

**Details**

`factor.scope` is not intended to be called directly by users.

**Value**

For `add.scope` and `drop.scope` a character vector of terms labels. For `factor.scope`, a list with components `drop` and `add`, character vectors of terms labels.
family

# [1] "c" "a:b"

family

Family Objects for Models

Description

Family objects provide a convenient way to specify the details of the models used by functions such as glm. See the documentation for glm for the details on how such model fitting takes place.

Usage

family(object, ...)

binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
quasibinomial(link = "logit")
quasipoisson(link = "log")

Arguments

link a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector or an object of class "link-glm" (such as generated by make.link) provided it is not specified via one of the standard names given next.

The gaussian family accepts the links (as names) identity, log and inverse; the binomial family the links logit, probit, cauchit, (corresponding to logistic, normal and Cauchy CDFs respectively) log and cloglog (complementary log-log); the Gamma family the links inverse, identity and log; the poisson family the links log, identity, and sqrt and the inverse. gaussian family the links 1/mu^2, inverse, identity and log.

The quasi family accepts the links logit, probit, cloglog, identity, inverse, log, 1/mu^2 and sqrt, and the function power can be used to create a power link function.

variance for all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)", "mu", "mu^2" and "mu^3", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.
object the function family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).

... further arguments passed to methods.

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

For the binomial and quasibinomial families the response can be specified in one of three ways:

1. As a factor: 'success' is interpreted as the factor not having the first level (and hence usually of having the second level).
2. As a numerical vector with values between 0 and 1, interpreted as the proportion of successful cases (with the total number of cases given by the weights).
3. As a two-column integer matrix: the first column gives the number of successes and the second the number of failures.

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

family character: the family name.
link character: the link name.
linkfun function: the link.
linkinv function: the inverse of the link function.
variance function: the variance as a function of the mean.
dev.resids function giving the deviance residuals as a function of (y, mu, wt).
aic function giving the AIC value if appropriate (but NA for the quasi- families). See logLik for the assumptions made about the dispersion parameter.
mu.eta function: derivative function(eta) dµ/df.
initialize expression. This needs to set up whatever data objects are needed for the family as well as n (needed for AIC in the binomial family) and mustart (see glm).
validmu logical function. Returns TRUE if a mean vector mu is within the domain of variance.
valideta logical function. Returns TRUE if a linear predictor eta is within the domain of linkinv.
simulate (optional) function simulate(object, nsim) to be called by the "lm" method of simulate. It will normally return a matrix with nsim columns and one row for each fitted value, but it can also return a list of length nsim. Clearly this will be missing for 'quasi-' families.
Note

The link and variance arguments have rather awkward semantics for back-compatibility. The recommended way is to supply them as quoted character strings, but they can also be supplied unquoted (as names or expressions). In addition, they can also be supplied as a length-one character vector giving the name of one of the options, or as a list (for link, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to \texttt{make.link} are accepted.

This is potentially ambiguous: supplying \texttt{link = logit} could mean the unquoted name of a link or the value of object \texttt{logit}. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via \texttt{logit[1]}.)

Author(s)

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except quasibinomial and quasipoisson).

## for Poisson results use
anova(glm.qD93, dispersion = 1, test = "Chisq")
summary(glm.qD93, dispersion = 1)

## Example of user-specified link, a logit model for \( p \cdot \text{days} \)
logexp <- function(days = 1)
{
  linkfun <- function(mu) qlogis(mu^((1/days)))
  linkinv <- function(eta) plogis(eta)^days
  mu.eta <- function(eta) days * plogis(eta)^((days-1) * binomial()$mu.eta
  valideta <- function(eta) TRUE
  link <- paste0("logexp", "", days, "")
  structure(list(linkfun = linkfun, linkinv = linkinv,
                mu.eta = mu.eta, valideta = valideta, name = link),
                class = "link-glm")
}
binomial(logexp(3))
## in practice this would be used with a vector of 'days', in
## which case use an offset of 0 in the corresponding formula
## to get the null deviance right.

## Binomial with identity link: often not a good idea.
## Not run: binomial(link = make.link("identity"))

## tests of quasi
x <- rnorm(100)
y <- rpois(100, exp(1+x))
glm(y ~ x, family = quasi(variance = "mu", link = "log"))
# which is the same as
glm(y ~ x, family = poisson)
glm(y ~ x, family = quasi(variance = "mu^2", link = "log"))
## Not run: glm(y ~ x, family = quasi(variance = "mu^3", link = "log")) # fails
y <- rbinom(100, 1, plogis(x))
# needs to set a starting value for the next fit
glm(y ~ x, family = quasi(variance = "mu(1-mu)", link = "logit"), start = c(0,1))
Arguments

- \(x, q\): vector of quantiles.
- \(p\): vector of probabilities.
- \(n\): number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.
- \(\text{df1}, \text{df2}\): degrees of freedom. \(\text{Inf}\) is allowed.
- \(\text{ncp}\): non-centrality parameter. If omitted the central F is assumed.
- \(\log, \log.p\): logical; if TRUE, probabilities \(p\) are given as \(\log(p)\).
- \(\text{lower.tail}\): logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

The F distribution with \(\text{df1} = n_1\) and \(\text{df2} = n_2\) degrees of freedom has density

\[
f(x) = \frac{\Gamma(n_1/2 + n_2/2)}{\Gamma(n_1/2)\Gamma(n_2/2)} \left(\frac{n_1}{n_2}\right)^{n_1/2} x^{n_1/2 - 1} \left(1 + \frac{n_1 x}{n_2}\right)^{-(n_1+n_2)/2}
\]

for \(x > 0\).

It is the distribution of the ratio of the mean squares of \(n_1\) and \(n_2\) independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of \(m\) independent normals has a Student’s \(t_m\) distribution, the square of a \(t_m\) variate has a F distribution on 1 and \(m\) degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and \(\text{ncp}\) is the sum of squares of the means. See \texttt{Chisquare} for further details on non-central distributions.

Value

- \(\text{df}\) gives the density, \(\text{pf}\) gives the distribution function \(\text{qf}\) gives the quantile function, and \(\text{rf}\) generates random deviates.

Invalid arguments will result in return value \texttt{NaN}, with a warning.

The length of the result is determined by \(n\) for \(\text{rf}\), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \(n\) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying \(\text{ncp} = 0\) uses the algorithm for the non-central distribution, which is not the same algorithm used if \(\text{ncp}\) is omitted. This is to give consistent behaviour in extreme cases with values of \(\text{ncp}\) very near zero.

The code for non-zero \(\text{ncp}\) is principally intended to be used for moderate values of \(\text{ncp}\): it will not be highly accurate, especially in the tails, for large values.

Source

For the central case of \(\text{df}\), computed \textit{via} a binomial probability, code contributed by Catherine Loader (see \texttt{dbinom}); for the non-central case computed \textit{via} \texttt{dbeta}, code contributed by Peter Ruckdeschel.

For \(\text{pf}\), \textit{via} \texttt{pbeta} (or for large \text{df2}, \textit{via} \texttt{pchisq}).

For \(\text{qf}\), \textit{via} \texttt{qchisq} for large \text{df2}, else \textit{via} \texttt{qbeta}.

Examples

```r
## Equivalence of pt(.,nu) with pf(.,^2, 1,nu):
x <- seq(0.001, 5, len = 100)
nu <- 4
stopifnot(all.equal(2*pt(x,nu) - 1, pf(x^2, 1,nu)),
## upper tails:
    all.equal(2*pt(x, nu, lower=FALSE),
               pf(x^2, 1,nu, lower=FALSE))

## the density of the square of a t_m is 2*dt(x, m)/(2*x)
# check this is the same as the density of F_{1,m}
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

## Identity: qf(2*p - 1, 1, df) == qt(p, df)^2) for p >= 1/2
p <- seq(1/2, .99, length = 50); df <- 10
rel.err <- function(x, y) ifelse(x == y, 0, abs(x-y)/mean(abs(c(x,y))))
quantile(rel.err(qf(2*p - 1, df1 = 1, df2 = df), qt(p, df)^2), .90) # ~= 7e-9
```

fft

*Fast Discrete Fourier Transform (FFT)*

Description

Computes the Discrete Fourier Transform (DFT) of an array with a fast algorithm, the “Fast Fourier Transform” (FFT).

Usage

```r
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

Arguments

- `z` a real or complex array containing the values to be transformed. Long vectors are not supported.
- `inverse` if TRUE, the unnormalized inverse transform is computed (the inverse has a \(+\) in the exponent of \(e\), but here, we do not divide by \(1/\text{length}(x)\)).
Value

When \( z \) is a vector, the value computed and returned by \( \text{fft} \) is the unnormalized univariate discrete Fourier transform of the sequence of values in \( z \). Specifically, \( y \leftarrow \text{fft}(z) \) returns

\[
y[h] = \sum_{k=1}^{n} z[k] \exp(-2\pi i (k - 1)(h - 1)/n)
\]

for \( h = 1, \ldots, n \) where \( n = \text{length}(y) \). If \( \text{inverse} \) is \( \text{TRUE} \), \( \exp(-2\pi \ldots) \) is replaced with \( \exp(2\pi \ldots) \).

When \( z \) contains an array, \( \text{fft} \) computes and returns the multivariate (spatial) transform. If \( \text{inverse} \) is \( \text{TRUE} \), the (unnormalized) inverse Fourier transform is returned, i.e., if \( y \leftarrow \text{fft}(z) \), then \( z \) is \( \text{fft}(y, \text{inverse} = \text{TRUE}) / \text{length}(y) \).

By contrast, \( \text{mvfft} \) takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

filter

Linear Filtering on a Time Series

Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

Usage

filter(x, filter, method = c("convolution", "recursive"),
       sides = 2, circular = FALSE, init)

Arguments

x
  a univariate or multivariate time series.
filter
  a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
method
  Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used: if "recursive" an autoregression is used.
sides
  for convolution filters only. If sides = 1 the filter coefficients are for past values only; if sides = 2 they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.
circular
  for convolution filters only. If TRUE, wrap the filter around the ends of the series, otherwise assume external values are missing (NA).
init
  for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.

Details

Missing values are allowed in x but not in filter (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

\[ y_i = x_i + f_1 y_{i-1} + \cdots + f_p y_{i-p} \]

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

\[ y_i = f_1 x_{i+o} + \cdots + f_p x_{i+o-(p-1)} \]

where o is the offset: see sides for how it is determined.
fisher.test

Value
A time series object.

Note
convolve(type = "filter") uses the FFT for computations and so may be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. filter is faster for a filter of length 100 on a series of length 1000, for example.

See Also
convolve, arima.sim

Examples
x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)
filter(presidents, rep(1, 3))

fisher.test

Fisher's Exact Test for Count Data

Description
Performs Fisher's exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

Usage
fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
            hybridPars = c(expect = 5, percent = 80, Emin = 1),
            control = list(), or = 1, alternative = "two.sided",
            conf.int = TRUE, conf.level = 0.95,
            simulate.p.value = FALSE, B = 2000)

Arguments
x
  either a two-dimensional contingency table in matrix form, or a factor object.

y
  a factor object; ignored if x is a matrix.

workspace
  an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than 2 × 2 tables. Since R version 3.5.0, this also increases the internal stack size which allows larger problems to be solved, however sometimes needing hours. In such cases, simulate.p.values=TRUE may be more reasonable.

hybrid
  a logical. Only used for larger than 2 × 2 tables, in which cases it indicates whether the exact probabilities (default) or a hybrid approximation thereof should be computed.
hybridPars  a numeric vector of length 3, by default describing “Cochran’s conditions” for the validity of the chisquare approximation, see ‘Details’.

control  a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer ≥ 2 with default 30 used only for larger than 2 × 2 tables. This says how many times as much space should be allocated to paths as to keys: see file ‘fexact.c’ in the sources of this package.

or  the hypothesized odds ratio. Only used in the 2 × 2 case.

alternative  indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 × 2 case.

conf.int  logical indicating if a confidence interval for the odds ratio in a 2 × 2 table should be computed (and returned).

conf.level  confidence level for the returned confidence interval. Only used in the 2 × 2 case and if conf.int = TRUE.

simulate.p.value  a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than 2 × 2 tables.

B  an integer specifying the number of replicates used in the Monte Carlo test.

Details

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For 2 × 2 cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1983, 1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from http://www.netlib.org/toms/643. Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than 2^{31} − 1.)

For 2 × 2 tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. ‘Exact’ inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so alternative = "greater" is a test of the odds ratio being bigger than or.

Two-sided tests are based on the probabilities of the tables, and take as ‘more extreme’ all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than 2 × 2 tables and hybrid = TRUE, asymptotic chi-squared probabilities are only used if the ‘Cochran conditions’ (or modified version thereof) specified by hybridPars = c(expect = 5, percent = 80, Emin = 1) are satisfied, that is if no cell has expected counts less than 1 (= Emin) and more than 80% (= percent) of the cells have expected counts at least 5 (= expect), otherwise the exact calculation is used. A corresponding if() decision is made for all sub-tables considered.

Accidentally, R has used 180 instead of 80 as percent, i.e., hybridPars[2] in R versions between 3.0.0 and 3.4.1 (inclusive), i.e., the 2nd of the hybridPars (all of which used to be hard-coded previous to R 3.5.0). Consequently, in these versions of R, hybrid=TRUE never made a difference.
In the $r \times c$ case with $r > 2$ or $c > 2$, internal tables can get too large for the exact test in which case an error is signalled. Apart from increasing workspace sufficiently, which then may lead to very long running times, using simulate.p.value = TRUE may then often be sufficient and hence advisable.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

Value

A list with class "htest" containing the following components:

- **p.value** the p-value of the test.
- **conf.int** a confidence interval for the odds ratio. Only present in the $2 \times 2$ case and if argument conf.int = TRUE.
- **estimate** an estimate of the odds ratio. Note that the conditional Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the $2 \times 2$ case.
- **null.value** the odds ratio under the null, or. Only present in the $2 \times 2$ case.
- **alternative** a character string describing the alternative hypothesis.
- **method** the character string "Fisher’s Exact Test for Count Data".
- **data.name** a character string giving the names of the data.

### fitted

Extract Model Fitted Values

**Description**

fitted is a generic function which extracts fitted values from objects returned by modeling functions. fitted.values is an alias for it.

All object classes which are returned by model fitting functions should provide a fitted method. (Note that the generic is fitted and not fitted.values.)
Methods can make use of \texttt{napredict} methods to compensate for the omission of missing values. The default and \texttt{nls} methods do.

\textbf{Usage}

\begin{verbatim}
  fitted(object, ...)  
fitted.values(object, ...)
\end{verbatim}

\textbf{Arguments}

- \texttt{object}: an object for which the extraction of model fitted values is meaningful.
- \texttt{...}: other arguments.

\textbf{Value}

Fitted values extracted from the object \texttt{object}.

\textbf{References}

\textbf{See Also}

\texttt{coefficients, glm, lm, residuals}.

---

\textbf{fivenum} \hspace{1.5in} \textit{Tukey Five-Number Summaries}

\textbf{Description}

Returns Tukey's five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

\textbf{Usage}

\begin{verbatim}
  fivenum(x, na.rm = TRUE)
\end{verbatim}

\textbf{Arguments}

- \texttt{x}: numeric, maybe including \texttt{NA}s and \pm \texttt{Inf}s.
- \texttt{na.rm}: logical; if TRUE, all \texttt{NA} and \texttt{NaN}s are dropped, before the statistics are computed.

\textbf{Value}

A numeric vector of length 5 containing the summary information. See \texttt{boxplot.stats} for more details.

\textbf{See Also}

\texttt{IQR, boxplot.stats, median, quantile, range}.

\textbf{Examples}

\begin{verbatim}
  fivenum(c(rnorm(100), -1:1/0))
\end{verbatim}
fligner.test \hspace{1cm} Fligner-Killeen Test of Homogeneity of Variances

**Description**

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

**Usage**

fligner.test(x, ...)

## Default S3 method:
fligner.test(x, g, ...)

## S3 method for class 'formula'
fligner.test(formula, data, subset, na.action, ...)

**Arguments**

x \hspace{1cm} a numeric vector of data values, or a list of numeric data vectors.

g \hspace{1cm} a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.

formula \hspace{1cm} a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.

data \hspace{1cm} an optional matrix or data frame (or similar: see \texttt{model.frame}) containing the variables in the formula \texttt{formula}. By default the variables are taken from \texttt{environment(formula)}.

subset \hspace{1cm} an optional vector specifying a subset of observations to be used.

na.action \hspace{1cm} a function which indicates what should happen when the data contain NAs. Defaults to \texttt{getOption("na.action")}.

... \hspace{1cm} further arguments to be passed to or from methods.

**Details**

If x is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use \texttt{fligner.test(x)} to perform the test. If the samples are not yet contained in a list, use \texttt{fligner.test(list(x, ...))}.

Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a k-sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights $a(i) = \texttt{qnorm}((1+i/(n+1))/2)$. The version implemented here uses median centering in each of the samples (F-K:med $X^2$ in the reference).
A list of class "htest" containing the following components:

- **statistic**: the Fligner-Killeen:med $X^2$ test statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Fligner-Killeen test of homogeneity of variances".
- **data.name**: a character string giving the names of the data.

**References**

**See Also**

- `ansari.test` and `mood.test` for rank-based two-sample test for a difference in scale parameters;
- `var.test` and `bartlett.test` for parametric tests for the homogeneity of variances.

**Examples**

```r
require(graphics)
plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()
```

---

### formula

#### Model Formulae

The generic function `formula` and its specific methods provide a way of extracting formulae which have been included in other objects.

- `as.formula` is almost identical, additionally preserving attributes when object already inherits from "formula".

#### Usage

- `formula(x, ...)`
- `as.formula(object, env = parent.frame())`

## S3 method for class 'formula'

- `print(x, showEnv = !identical(e, .GlobalEnv), ...)`
Arguments

- \texttt{x, object} \hspace{1cm} \texttt{R object.}
- \texttt{...} \hspace{1cm} further arguments passed to or from other methods.
- \texttt{env} \hspace{1cm} the environment to associate with the result, if not already a formula.
- \texttt{showEnv} \hspace{1cm} logical indicating if the environment should be printed as well.

Details

The models fit by, e.g., the \texttt{lm} and \texttt{glm} functions are specified in a compact symbolic form. The \texttt{~} operator is basic in the formation of such models. An expression of the form \texttt{y \sim model} is interpreted as a specification that the response \texttt{y} is modelled by a linear predictor specified symbolically by \texttt{model}. Such a model consists of a series of terms separated by \texttt{+} operators. The terms themselves consist of variable and factor names separated by \texttt{:} operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to \texttt{+} and \texttt{:}, a number of other operators are useful in model formulae. The \texttt{*} operator denotes factor crossing: \texttt{a*b} interpreted as \texttt{a+b+a:b}. The \texttt{^} operator indicates crossing to the specified degree. For example \texttt{(a+b+c)^2} is identical to \texttt{(a+b+c)*(a+b+c)} which in turn expands to a formula containing the main effects for \texttt{a, b} and \texttt{c} together with their second-order interactions. The \texttt{%in%} operator indicates that the terms on its left are nested within those on the right. For example \texttt{a + b \%in% a} expands to the formula \texttt{a + a:b}. The \texttt{-} operator removes the specified terms, so that \texttt{(a+b+c)^2 - a:b} is identical to \texttt{a + b + c + b:c + a:c}. It can also used to remove the intercept term: when fitting a linear model \texttt{y \sim x - 1} specifies a line through the origin. A model with no intercept can be also specified as \texttt{y \sim x + 0} or \texttt{y \sim 0 + x}.

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula \texttt{log(y) \sim a + log(x)} is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function \texttt{I()} can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula \texttt{y ~ a + I(b+c)}, the term \texttt{b+c} is to be interpreted as the sum of \texttt{b} and \texttt{c}.

Variable names can be quoted by backticks `like this` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function \texttt{offset} to indicate terms with a fixed coefficient of one. Some functions accept other `specials` such as \texttt{strata} or \texttt{cluster} (see the \texttt{specials} argument of \texttt{terms.formula}).

There are two special interpretations of \texttt{.} in a formula. The usual one is in the context of a data argument of model fitting functions and means `all columns not otherwise in the formula`: see \texttt{terms.formula}. In the context of \texttt{update.formula, only}, it means `what was previously in this part of the formula`.

When \texttt{formula} is called on a fitted model object, either a specific method is used (such as that for class `"nls"`) or the default method. The default first looks for a "formula" component of the object (and evaluates it), then a "terms" component, then a \texttt{formula} parameter of the call (and evaluates its value) and finally a "formula" attribute.

There is a \texttt{formula} method for data frames. If there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by \texttt{+} form the RHS.
Value

All the functions above produce an object of class "formula" which contains a symbolic model formula.

Environments

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied data argument.

Formulas created with the `~` operator use the environment in which they were created. Formulas created with `as.formula` will use the `env` argument for their environment.

`I`, `offset`.

For formula manipulation: `terms`, and `all.vars`; for typical use: `lm`, `glm`, and `coplot`.

Examples

```r
class(fo <- y ~ x1*x2) # "formula"
fo
typeof(fo) # R internal : "language"
terms(fo)

environment(fo)
environment(as.formula("y ~ x"))
environment(as.formula("y ~ x", env = new.env()))

### Create a formula for a model with a large number of variables:
xnam <- paste0("x", 1:25)
(fmla <- as.formula(paste("y ~ ", paste(xnam, collapse= "+"))))
```

---

**formula.nls**

*Extract Model Formula from nls Object*

**Description**

Returns the model used to fit object.

**Usage**

```r
## S3 method for class 'nls'
formula(x, ...)
```
friedman.test

Arguments

x an object inheriting from class "nls", representing a nonlinear least squares fit.

... further arguments passed to or from other methods.

Value

a formula representing the model used to obtain object.

Author(s)

José Pinheiro and Douglas Bates

See Also

nls, formula

Examples

fm1 <- nls(circumference ~ A/(1+exp((B-age)/C)), Orange,
            start = list(A = 160, B = 700, C = 350))
formula(fm1)

Description

Performs a Friedman rank sum test with unreplicated blocked data.

Usage

friedman.test(y, ...)

## Default S3 method:
friedman.test(y, groups, blocks, ...)

## S3 method for class 'formula'
friedman.test(formula, data, subset, na.action, ...)

Arguments

y either a numeric vector of data values, or a data matrix.
groups a vector giving the group for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
blocks a vector giving the block for the corresponding elements of y if this is a vector; ignored if y is a matrix. If not a factor object, it is coerced to one.
formula a formula of the form a ~ b | c, where a, b and c give the data values and corresponding groups and blocks, respectively.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
friedman.test

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... further arguments to be passed to or from methods.

Details

friedman.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in y for each combination of levels of groups and blocks) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of y is the same in each of the groups.

If y is a matrix, groups and blocks are obtained from the column and row indices, respectively. NA's are not allowed in groups or blocks; if y contains NA's, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

statistic the value of Friedman's chi-squared statistic.

parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic.

p.value the p-value of the test.

method the character string "Friedman rank sum test".

data.name a character string giving the names of the data.

---

**ftable**

*Flat Contingency Tables*

**Description**

Create ‘flat’ contingency tables.

**Usage**

```
ftable(x, ...)
```

## Default S3 method:
ftable(..., exclude = c(NA, NaN), row.vars = NULL, 
col.vars = NULL)

**Arguments**

- `x, ...` R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, or a contingency table object of class "table" or "ftable".
- `exclude` values to use in the exclude argument of factor when interpreting non-factor objects.
- `row.vars` a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the rows of the flat contingency table.
col.vars  a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the columns of the flat contingency table.

Details

`ftable` creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the counts of each combination of the levels of the variables (factors) involved. This information is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the levels of the row and column variables (as specified by `row.vars` and `col.vars`, respectively). The combinations are created by looping over the variables in reverse order (so that the levels of the left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via `print.ftable`, the print method for objects of class "ftable") is often preferable to showing it as a higher-dimensional array.

`ftable` is a generic function. Its default method, `ftable.default`, first creates a contingency table in array form from all arguments except `row.vars` and `col.vars`. If the first argument is of class "table", it represents a contingency table and is used as is; if it is a flat table of class "ftable", the information it contains is converted to the usual array representation using `as.ftable`. Otherwise, the arguments should be R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using `table`. Then, the arguments `row.vars` and `col.vars` are used to collapse the contingency table into flat form. If neither of these two is given, the last variable is used for the columns. If both are given and their union is a proper subset of all variables involved, the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed to `table` to control how the variable names are displayed; see the last example below.

Function `ftable.formula` provides a formula method for creating flat contingency tables.

There are methods for `as.table`, `as.matrix` and `as.data.frame`.

Value

`ftable` returns an object of class "ftable", which is a matrix with counts of each combination of the levels of variables with information on the names and levels of the (row and columns) variables stored as attributes "row.vars" and "col.vars".

See Also

`ftable.formula` for the formula interface (which allows a `data = .` argument); `read.ftable` for information on reading, writing and coercing flat contingency tables; `table` for ordinary cross-tabulation; `xtabs` for formula-based cross-tabulation.

Examples

```r
## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))
```
## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
dnn = c("Cylinders", "V/S", "Transmission", "Gears"))

---

**ftable.formula**

*Formula Notation for Flat Contingency Tables*

### Description

Produce or manipulate a flat contingency table using formula notation.

### Usage

```r
## S3 method for class 'formula'
ftable(formula, data = NULL, subset, na.action, ...)
```

### Arguments

- **formula**: a formula object with both left and right hand sides specifying the column and row variables of the flat table.
- **data**: a data frame, list or environment (or similar: see `model.frame`) containing the variables to be cross-tabulated, or a contingency table (see below).
- **subset**: an optional vector specifying a subset of observations to be used. Ignored if `data` is a contingency table.
- **na.action**: a function which indicates what should happen when the data contain `NA`s. Ignored if `data` is a contingency table.
- **...**: further arguments to the default `ftable` method may also be passed as arguments, see `ftable.default`.

### Details

This is a method of the generic function `ftable`.

The left and right hand side of `formula` specify the column and row variables, respectively, of the flat contingency table to be created. Only the `+` operator is allowed for combining the variables. A `.` may be used once in the formula to indicate inclusion of all the remaining variables.

If `data` is an object of class "table" or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class "ftable"), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, `na.action` is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the `subset` argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by `formula`.

### Value

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.
**GammaDist**

### Description
Density, distribution function, quantile function and random generation for the Gamma distribution with parameters `shape` and `scale`.

### Usage
- `dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)`
- `pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)`
- `qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE, log.p = FALSE)`
- `rgamma(n, shape, rate = 1, scale = 1/rate)`

### Arguments
- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `rate` an alternative way to specify the scale.
- `shape, scale` shape and scale parameters. Must be positive, scale strictly.
- `log, log.p` logical; if `TRUE`, probabilities/densities `p` are returned as `log(p)`.
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

### Details
If `scale` is omitted, it assumes the default value of 1.

The Gamma distribution with parameters `shape = α` and `scale = σ` has density

$$f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha - 1} e^{-x/\sigma}$$

for $x \geq 0$, $\alpha > 0$ and $\sigma > 0$. (Here \(\Gamma(\alpha)\) is the function implemented by R’s `gamma()` and defined in its help. Note that $\alpha = 0$ corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are $E(X) = \alpha \sigma$ and $Var(X) = \alpha \sigma^2$.

The cumulative hazard $H(t) = -\log(1 - F(t))$ is

---

**See Also**
- `ftable`, `ftable.default`, `table`

**Examples**

```r
titanic <- ftable(Survived ~ ., data = Titanic)
titanic
ftable(Sex ~ Class + Age, data = titanic)
```
\texttt{-pgamma(t, ..., lower = FALSE, log = TRUE)}

Note that for smallish values of shape (and moderate scale) a large parts of the mass of the Gamma distribution is on values of \(x\) so near zero that they will be represented as zero in computer arithmetic. So \texttt{rgamma} may well return values which will be represented as zero. (This will also happen for very large values of scale since the actual generation is done for scale = 1.)

**Value**

d\texttt{gamma} gives the density, \texttt{pgamma} gives the distribution function, \texttt{qgamma} gives the quantile function, and \texttt{rgamma} generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by \(n\) for \texttt{rgamma}, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \(n\) are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The S (Becker et al (1988)) parametrization was via shape and rate: S had no scale parameter. It is an error to supply and scale and rate.

\texttt{pgamma} is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by ‘Numerical Recipes’) this is

\[
P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1}e^{-t}dt
\]

\(P(a, x)\) is \texttt{pgamma}(x, a). Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function \(\gamma(a, x)\) as \(\gamma(a, x) = \int_0^x t^{a-1}e^{-t}dt\), i.e., \texttt{pgamma}(x, a) * \texttt{gamma}(a). Yet others use the ‘upper’ incomplete gamma function,

\[
\Gamma(a, x) = \int_x^\infty t^{a-1}e^{-t}dt,
\]

which can be computed by \texttt{pgamma}(x, a, lower = FALSE) * \texttt{gamma}(a).

Note however that \texttt{pgamma}(x, a, ...) currently requires \(a > 0\), whereas the incomplete gamma function is also defined for negative \(a\). In that case, you can use \texttt{gamma_inc(a,x)} (for \(\Gamma(a, x)\)) from package \texttt{gsl}.

See also https://en.wikipedia.org/wiki/Incomplete_gamma_function, or http://dlmf.nist.gov/8.2#i.

**Source**

d\texttt{gamma} is computed via the Poisson density, using code contributed by Catherine Loader (see \texttt{dbinom}).

\texttt{pgamma} uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.

\texttt{qgamma} is based on a C translation of

plus a final Newton step to improve the approximation.
rgamma for shape >= 1 uses
and for 0 < shape < 1 uses

Examples
```
-log(dgamma(1:4, shape = 1))
p <- (1:9)/10
pgamma(qgamma(p, shape = 2), shape = 2)
1 - 1/exp(qgamma(p, shape = 1))
# even for shape = 0.001 about half the mass is on numbers
# that cannot be represented accurately (and most of those as zero)
pgamma(.Machine$double.xmin, 0.001)
pgamma(5e-324, 0.001) # on most machines 5e-324 is the smallest
# representable non-zero number
table(rgamma(1e4, 0.001) == 0)/1e4
```

---

**Geometric**

*The Geometric Distribution*

**Description**

Density, distribution function, quantile function and random generation for the geometric distribution with parameter prob.

**Usage**

`dgeom(x, prob, log = FALSE)`
`pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)`
`qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)`
`rgeom(n, prob)`
Arguments

\(x, \ q\)
vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.

\(p\)
vector of probabilities.

\(n\)
number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.

\(\text{prob}\)
probability of success in each trial. \(0 < \text{prob} \leq 1\).

\(\log, \ \log.p\)
logical; if TRUE, probabilities \(p\) are given as \(\log(p)\).

\(\text{lower.tail}\)
logical; if TRUE (default), probabilities are \(P[X \leq x]\), otherwise, \(P[X > x]\).

Details

The geometric distribution with \(\text{prob} = p\) has density

\[p(x) = p(1 - p)^x\]

for \(x = 0, 1, 2, \ldots, 0 < p \leq 1\).

If an element of \(x\) is not integer, the result of \(\text{dgeom}\) is zero, with a warning.

The quantile is defined as the smallest value \(x\) such that \(F(x) \geq p\), where \(F\) is the distribution function.

Value

dgeom gives the density, pgeom gives the distribution function, qgeom gives the quantile function, and rgeom generates random deviates.

Invalid prob will result in return value NaN, with a warning.

The length of the result is determined by \(n\) for rgeom, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \(n\) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dgeom computes via dbinom, using code contributed by Catherine Loader (see dbinom).
pgeom and qgeom are based on the closed-form formulae.
rgeom uses the derivation as an exponential mixture of Poissons, see

See Also

Distributions for other standard distributions, including dnbino for the negative binomial which generalizes the geometric distribution.

Examples

qgeom((1:9)/10, prob = .2)
Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))
getInitial

Get Initial Parameter Estimates

Description

This function evaluates initial parameter estimates for a nonlinear regression model. If data is a parameterized data frame or pframe object, its parameters attribute is returned. Otherwise the object is examined to see if it contains a call to a selfStart object whose initial attribute can be evaluated.

Usage

generic function getInitial(object, data, ...)

Arguments

- object: a formula or a selfStart model that defines a nonlinear regression model
- data: a data frame in which the expressions in the formula or arguments to the selfStart model can be evaluated
- ...: optional additional arguments

Value

A named numeric vector or list of starting estimates for the parameters. The construction of many selfStart models is such that these "starting" estimates are, in fact, the converged parameter estimates.

Author(s)

José Pinheiro and Douglas Bates

```
glm

Fitting Generalized Linear Models

Description

glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

Usage

```r
glm(formula, family = gaussian, data, weights, subset,
    na.action, start = NULL, etastart, mustart, offset,
    control = list(...), model = TRUE, method = "glm.fit",
    x = FALSE, y = TRUE, singular.ok = TRUE, contrasts = NULL, ...)
```

```r
glm.fit(x, y, weights = rep(1, nobs),
    start = NULL, etastart = NULL, mustart = NULL,
    offset = rep(0, nobs), family = gaussian(),
    control = list(), intercept = TRUE, singular.ok = TRUE)
```

## S3 method for class 'glm'
weights(object, type = c("prior", "working"), ...)

Arguments

- **formula**: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.

- **family**: a description of the error distribution and link function to be used in the model. For glm this can be a character string naming a family function, a family function or the result of a call to a family function. For glm.fit only the third option is supported. (See family for details of family functions.)

- **data**: an optional data frame, list or environment (or object coercible by `as.data.frame`) containing the variables in the model. If not found in data, the variables are taken from `environment(formula)`, typically the environment from which glm is called.

- **weights**: an optional vector of ‘prior weights’ to be used in the fitting process. Should be NULL or a numeric vector.

- **subset**: an optional vector specifying a subset of observations to be used in the fitting process.

- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`. Another possible value is `NULL`, no action. Value `na.exclude` can be useful.

- **start**: starting values for the parameters in the linear predictor.

- **etastart**: starting values for the linear predictor.

- **mustart**: starting values for the vector of means.
offset this can be used to specify an *a priori* known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more `offset` terms can be included in the formula instead or as well, and if more than one is specified their sum is used. See `model.offset`.

ccontrol a list of parameters for controlling the fitting process. For `glm.fit` this is passed to `glm.control`.

model a logical value indicating whether `model.frame` should be included as a component of the returned value.

method the method to be used in fitting the model. The default method "glm.fit" uses iteratively reweighted least squares (IWLS): the alternative "model.frame" returns the model frame and does no fitting.

User-supplied fitting functions can be supplied either as a function or a character string naming a function, with a function which takes the same arguments as `glm.fit`. If specified as a character string it is looked up from within the `stats` namespace.

x, y For `glm`: logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value.

For `glm.fit`: x is a design matrix of dimension n \times p, and y is a vector of observations of length n.

singular.ok logical; if FALSE a singular fit is an error.

contrasts an optional list. See the `contrasts.arg` of `model.matrix.default`.

intercept logical. Should an intercept be included in the null model?

object an object inheriting from class "glm".

type character, partial matching allowed. Type of weights to extract from the fitted model object. Can be abbreviated.

... For `glm`: arguments to be used to form the default `control` argument if it is not supplied directly.

For `weights`: further arguments passed to or from other methods.

Details

A typical predictor has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. For binomial and quasibinomial families the response can also be specified as a `factor` (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with any duplicates removed.

A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the cross of `first` and `second`. This is the same as `first + second + first:second`.

The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula.

Non-NULL weights can be used to indicate that different observations have different dispersions (with the values in `weights` being inversely proportional to the dispersions); or equivalently, when the elements of `weights` are positive integers w_i, that each response y_i is the mean of w_i unit-weight observations. For a binomial GLM prior weights are used to give the number of trials when the response is the proportion of successes: they would rarely be used for a Poisson GLM.
**glm**

glm.fit is the workhorse function: it is not normally called directly but can be more efficient where the response vector, design matrix and family have already been calculated.

If more than one of etastart, start and mustart is specified, the first in the list will be used. It is often advisable to supply starting values for a quasi family, and also for families with unusual links such as gaussian("log").

All of weights, subset, offset, etastart and mustart are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

**Value**

glm returns an object of class inheriting from "glm" which inherits from the class "lm". See later in this section. If a non-standard method is used, the object will also inherit from the class (if any) returned by that function.

The function summary (i.e., summary.glm) can be used to obtain or print a summary of the results and the function anova (i.e., anova.glm) to produce an analysis of variance table.

The generic accessor functions coefficients, effects, fitted.values and residuals can be used to extract various useful features of the value returned by glm.

weights extracts a vector of weights, one for each case in the fit (after subsetting and na.action).

An object of class "glm" is a list containing at least the following components:

- **coefficients** a named vector of coefficients
- **residuals** the working residuals, that is the residuals in the final iteration of the IWLS fit.
  Since cases with zero weights are omitted, their working residuals are NA.
- **fitted.values** the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
- **rank** the numeric rank of the fitted linear model.
- **family** the family object used.
- **linear.predictors** the linear fit on link scale.
- **deviance** up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.
- **aic** A version of Akaike's *An Information Criterion*, minus twice the maximized log-likelihood plus twice the number of parameters, computed by the aic component of the family. For binomial and Poison families the dispersion is fixed at one and the number of parameters is the number of coefficients. For gaussian, Gamma and inverse gaussian families the dispersion is estimated from the residual deviance, and the number of parameters is the number of coefficients plus one. For a gaussian family the MLE of the dispersion is used so this is a valid value of AIC, but for Gamma and inverse gaussian families it is not. For families fitted by quasi-likelihood the value is NA.
- **null.deviance** The deviance for the null model, comparable with deviance. The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.
- **iter** the number of iterations of IWLS used.
- **weights** the working weights, that is the weights in the final iteration of the IWLS fit.
glm

prior.weights  the weights initially supplied, a vector of 1s if none were.
df.residual  the residual degrees of freedom.
df.null  the residual degrees of freedom for the null model.
y  if requested (the default) the y vector used. (It is a vector even for a binomial model.)
x  if requested, the model matrix.
model  if requested (the default), the model frame.
converged  logical. Was the IWLS algorithm judged to have converged?
boundary  logical. Is the fitted value on the boundary of the attainable values?
call  the matched call.
formula  the formula supplied.
terms  the terms object used.
data  the data argument.
offset  the offset vector used.
control  the value of the control argument used.
method  the name of the fitter function used, currently always "glm.fit".
contrasts  (where relevant) the contrasts used.
xlevels  (where relevant) a record of the levels of the factors used in fitting.
na.action  (where relevant) information returned by model.frame on the special handling of NAs.

In addition, non-empty fits will have components qr, R and effects relating to the final weighted linear fit.

Objects of class "glm" are normally of class c("glm", "lm"), that is inherit from class "lm", and well-designed methods for class "lm" will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class "glm" such as residuals and weights do not just pick out the component of the fit with the same name.

If a binomial glm model was specified by giving a two-column response, the weights returned by prior.weights are the total numbers of cases (factored by the supplied case weights) and the component y of the result is the proportion of successes.

Fitting functions

The argument method serves two purposes. One is to allow the model frame to be recreated with no fitting. The other is to allow the default fitting function glm.fit to be replaced by a function which takes the same arguments and uses a different fitting algorithm. If glm.fit is supplied as a character string it is used to search for a function of that name, starting in the stats namespace.

The class of the object return by the fitter (if any) will be prepended to the class returned by glm.

Author(s)

The original R implementation of glm was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team. The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

glm.control

Auxiliary for Controlling GLM Fitting

Description

Auxiliary function for glm fitting. Typically only used internally by glm.fit, but may be used to construct a control argument to either function.

Usage

glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)

Arguments

epsilon  positive convergence tolerance \( \epsilon \); the iterations converge when \( \frac{|\text{dev} - \text{dev}_{\text{old}}|}{|\text{dev}| + 0.1} < \epsilon \).

maxit    integer giving the maximal number of IWLS iterations.

trace    logical indicating if output should be produced for each iteration.

Details

The control argument of glm is by default passed to the control argument of glm.fit, which uses its elements as arguments to glm.control: the latter provides defaults and sanity checking.

If epsilon is small (less than \( 10^{-10} \)) it is also used as the tolerance for the detection of collinearity in the least squares solution.

When trace is true, calls to cat produce the output for each IWLS iteration. Hence, options(digits = *) can be used to increase the precision, see the example.

Value

A list with components named as the arguments.

References

glm.fit, the fitting procedure used by glm.
### A variation on example(glm):

```r
## Annette Dobson's example ...
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9)
treatment <- gl(3,3)

## S3 method for class 'glm'
family(object, ...)

## S3 method for class 'glm'
residuals(object, type = c("deviance", "pearson", "working", "response", "partial"), ...)

Arguments

object an object of class glm, typically the result of a call to glm.
type the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial". Can be abbreviated.
...

Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

For fits done with y = FALSE the response values are computed from other components.

---

**hclust**

*Hierarchical Clustering*

**Description**

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

**Usage**

```r
hclust(d, method = "complete", members = NULL)
plot(x, labels = NULL, hang = 0.1, check = TRUE, axes = TRUE, frame.plot = FALSE, ann = TRUE, main = "Cluster Dendrogram", sub = NULL, xlab = NULL, ylab = "Height", ...)```

**Arguments**

- `d`: a dissimilarity structure as produced by `dist`.
- `method`: the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward.D", "ward.D2", "single", "complete", "average" (= UPGMA), "mcquitty" (= WPGMA), "median" (= WPGMC) or "centroid" (= UPGMC).
- `members`: NULL or a vector with length size of `d`. See the ‘Details’ section.
- `x`: an object of the type produced by `hclust`.
- `hang`: The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
- `check`: logical indicating if the `x` object should be checked for validity. This check is not necessary when `x` is known to be valid such as when it is the direct result of `hclust()`. The default is `check=TRUE`, as invalid inputs may crash R due to memory violation in the internal C plotting code.
This function performs a hierarchical cluster analysis using a set of dissimilarities for the \( n \) objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. Ward’s minimum variance method aims at finding compact, spherical clusters. The complete linkage method finds similar clusters. The single linkage method (which is closely related to the minimal spanning tree) adopts a ‘friends of friends’ clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods "median" and "centroid" are not leading to a monotone distance measure, or equivalently the resulting dendrograms can have so called inversions or reversals which are hard to interpret, but note the trichotomies in Legendre and Legendre (2012).

Two different algorithms are found in the literature for Ward clustering. The one used by option "ward.D" (equivalent to the only Ward option "ward" in \( \mathbb{R} \) versions ≤ 3.0.3) does not implement Ward’s (1963) clustering criterion, whereas option "ward.D2" implements that criterion (Murtagh and Legendre 2014). With the latter, the dissimilarities are squared before cluster updating. Note that agnes(\( \ast \), method="ward") corresponds to hclust(\( \ast \), "ward.D2").

If \( \text{members} \neq \text{NULL} \), then \( d \) is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and \( \text{members} \) gives the number of observations per cluster. This way the hierarchical cluster algorithm can be ‘started in the middle of the dendrogram’, e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without hclust itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for \( n \) observations there are \( n - 1 \) merges, there are \( 2^{(n-1)} \) possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in hclust is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

Value

An object of class \textbf{hclust} which describes the tree produced by the clustering process. The object is a list with components:
**merge**

An \( n - 1 \) by 2 matrix. Row \( i \) of \texttt{merge} describes the merging of clusters at step \( i \) of the clustering. If an element \( j \) in the row is negative, then observation \( -j \) was merged at this stage. If \( j \) is positive then the merge was with the cluster formed at the (earlier) stage \( j \) of the algorithm. Thus negative entries in \texttt{merge} indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.

**height**

A set of \( n - 1 \) real values (non-decreasing for ultrametric trees). The clustering \texttt{height}: that is, the value of the criterion associated with the clustering method for the particular agglomeration.

**order**

A vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix \texttt{merge} will not have crossings of the branches.

**labels**

Labels for each of the objects being clustered.

**call**

The call which produced the result.

**method**

The cluster method that has been used.

**dist.method**

The distance that has been used to create \( d \) (only returned if the distance object has a "method" attribute).

There are \texttt{print}, \texttt{plot} and \texttt{identify} (see \texttt{identify.hclust}) methods and the \texttt{rect.hclust()} function for \texttt{hclust} objects.

**Note**

Method "centroid" is typically meant to be used with squared Euclidean distances.

**Author(s)**

The \texttt{hclust} function is based on Fortran code contributed to STATLIB by F. Murtagh.

opar <- par(mfrow = c(1, 2))
plot(hc1.D, hang=-1)
plot(hc1.D2, hang=-1)
par(opar)

---

Heatmap

**Draw a Heat Map**

Description

A heat map is a false color image (basically \texttt{image}(t(x))) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.
heatmap

Usage

heatmap(x, Rowv = NULL, Colv = if(symm)"Rowv" else NULL, 
distfun = dist, hclustfun = hclust, 
reorderfun = function(d, w) reorder(d, w), 
add.expr, symm = FALSE, revC = identical(Colv, "Rowv"), 
scale = c("row", "column", "none"), na.rm = TRUE, 
margins = c(5, 5), ColSideColors, RowSideColors, 
cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc), 
labRow = NULL, labCol = NULL, main = NULL, 
xlab = NULL, ylab = NULL, 
keep.dendro = FALSE, verbose =getOption("verbose"), ...)

Arguments

x numeric matrix of the values to be plotted.
Rowv determines if and how the row dendrogram should be computed and reordered. Either a dendrogram or a vector of values used to reorder the row dendrogram or NA to suppress any row dendrogram (and reordering) or by default, NULL, see 'Details' below.
Colv determines if and how the column dendrogram should be reordered. Has the same options as the Rowv argument above and additionally when x is a square matrix, Colv = "Rowv" means that columns should be treated identically to the rows (and so if there is to be no row dendrogram there will not be a column one either).
distfun function used to compute the distance (dissimilarity) between both rows and columns. Defaults to dist.
hclustfun function used to compute the hierarchical clustering when Rowv or Colv are not dendrograms. Defaults to hclust. Should take as argument a result of distfun and return an object to which as.dendrogram can be applied.
reorderfun function(d, w) of dendrogram and weights for reordering the row and column dendrograms. The default uses reorder.dendrogram.
add.expr expression that will be evaluated after the call to image. Can be used to add components to the plot.
symm logical indicating if x should be treated symmetrically; can only be true when x is a square matrix.
revC logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.
scale character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is "row" if symm false, and "none" otherwise.
na.rm logical indicating whether NA’s should be removed.
margins numeric vector of length 2 containing the margins (see par(mar = *)) for column and row names, respectively.
ColSideColors (optional) character vector of length ncol(x) containing the color names for a horizontal side bar that may be used to annotate the columns of x.
RowSideColors (optional) character vector of length nrow(x) containing the color names for a vertical side bar that may be used to annotate the rows of x.
cexRow, cexCol  positive numbers, used as cex.axis in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.
labRow, labCol  character vectors with row and column labels to use; these default to rownames(x) or colnames(x), respectively.
main, xlab, ylab  main, x- and y-axis titles; defaults to none.
keep.dendro  logical indicating if the dendrogram(s) should be kept as part of the result (when Rowv and/or Colv are not NA).
verbose  logical indicating if information should be printed.
...  additional arguments passed on to image, e.g., col specifying the colors.

Details
If either Rowv or Colv are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as dd <- as.dendrogram(hclustfun(distfun(X))) where X is either x or t(x).

If either is a vector (of ‘weights’) then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by reorder(dd, Rowv), in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, Rowv <- rowMeans(x, na.rm = na.rm). If either is NA, no reordering will be done for the corresponding side.

By default (scale = "row") the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

The default colors are not pretty. Consider using enhancements such as the RColorBrewer package.

Value
Invisibly, a list with components
rowInd  row index permutation vector as returned by order.dendrogram.
colInd  column index permutation vector.
Rowv  the row dendrogram; only if input Rowv was not NA and keep.dendro is true.
Colv  the column dendrogram; only if input Colv was not NA and keep.dendro is true.

Note
Unless Rowv = NA (or Colw = NA), the original rows and columns are reordered in any case to match the dendrogram, e.g., the rows by order.dendrogram(Rowv) where Rowv is the (possibly reorder(jed)) row dendrogram.
heatmap() uses layout and draws the image in the lower right corner of a 2x2 layout. Consecutively, it can not be used in a multi column/row layout, i.e., when par(mfrow = *) or (mfcol = *) has been called.

**HoltWinters**

**Holt-Winters Filtering**

**Description**

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

**Examples**

```r
require(graphics); require(grDevices)
x <- as.matrix(mtcars)
rc <- rainbow(nrow(x), start = 0, end = .3)
cc <- rainbow(ncol(x), start = 0, end = .3)

hv <- heatmap(x, col = cm.colors(256), scale = "column",
              RowSideColors = rc, ColSideColors = cc, margins = c(5,10),
              xlab = "specification variables", ylab = "Car Models",
              main = "heatmap(<Mtcars data>, ..., scale = \"column\")")
utils::str(hv) # the two re-ordering index vectors

## no column dendrogram (nor reordering) at all:
heatmap(x, Colv = NA, col = cm.colors(256), scale = "column",
        RowSideColors = rc, margins = c(5,10),
        xlab = "specification variables", ylab = "Car Models",
        main = "heatmap(<Mtcars data>, ..., scale = \"column\")")

## "no nothing"
heatmap(x, Rowv = NA, Colv = NA, scale = "column",
        main = "heatmap(*, NA, NA) \~= image(t(x))")

round(Ca <- cor(attitude), 2)
symnum(Ca) # simple graphic
heatmap(Ca, symm = TRUE, margins = c(6,6)) # with reorder()
heatmap(Ca, Rowv = FALSE, symm = TRUE, margins = c(6,6)) # _NO_ reorder()

## slightly artificial with color bar, without and with ordering:
cc <- rainbow(nrow(Ca))
heatmap(Ca, Rowv = FALSE, symm = TRUE, RowSideColors = cc, ColSideColors = cc,
        margins = c(6,6))
heatmap(Ca,symm = TRUE, RowSideColors = cc, ColSideColors = cc,
        margins = c(6,6))

## For variable clustering, rather use distance based on cor():
symnum( cu <- cor(USJudgeRatings) )

hU <- heatmap(cU, Rowv = FALSE, symm = TRUE, col = topo.colors(16),
              distfun = function(c) as.dist(1 - c), keep.dendro = TRUE)

## The Correlation matrix with same reordering:
round(100 * cu[hU[1], hU[2]]])

## The column dendrogram:
utils::str(hU$Colv)
```
Usage

HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
seasonal = c("additive", "multiplicative"),
start.periods = 2, l.start = NULL, b.start = NULL,
s.start = NULL,
optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1),
optim.control = list())

Arguments

x An object of class ts

alpha alpha parameter of Holt-Winters Filter.

beta beta parameter of Holt-Winters Filter. If set to FALSE, the function will do
exponential smoothing.

gamma gamma parameter used for the seasonal component. If set to FALSE, an non-
seasonal model is fitted.

seasonal Character string to select an "additive" (the default) or "multiplicative"
seasonal model. The first few characters are sufficient. (Only takes effect if
gamma is non-zero).

start.periods Start periods used in the autodetection of start values. Must be at least 2.

l.start Start value for level (a[0]).

b.start Start value for trend (b[0]).

s.start Vector of start values for the seasonal component (s[1][0] ... s[p][0])

optim.start Vector with named components alpha, beta, and gamma containing the starting
values for the optimizer. Only the values needed must be specified. Ignored in
the one-parameter case.

optim.control Optional list with additional control parameters passed to optim if this is used.
Ignored in the one-parameter case.

Details

The additive Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t + h] = a[t] + hb[t] + s[t - p + 1 + (h - 1) \mod p], \]

where \(a[t], b[t]\) and \(s[t]\) are given by

\[ a[t] = \alpha(Y[t] - s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \]
\[ b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \]
\[ s[t] = \gamma(Y[t] - a[t]) + (1 - \gamma)s[t - p] \]

The multiplicative Holt-Winters prediction function (for time series with period length p) is

\[ \hat{Y}[t + h] = (a[t] + hb[t]) \times s[t - p + 1 + (h - 1) \mod p], \]

where \(a[t], b[t]\) and \(s[t]\) are given by

\[ a[t] = \alpha(Y[t]/s[t - p]) + (1 - \alpha)(a[t - 1] + b[t - 1]) \]
\[ b[t] = \beta(a[t] - a[t - 1]) + (1 - \beta)b[t - 1] \]
$s[t] = \gamma(Y[t]/a[t]) + (1 - \gamma)s[t - p]$ 

The data in $x$ are required to be non-zero for a multiplicative model, but it makes most sense if they are all positive.

The function tries to find the optimal values of $\alpha$ and/or $\beta$ and/or $\gamma$ by minimizing the squared one-step prediction error if they are NULL (the default). `optimize` will be used for the single-parameter case, and `optim` otherwise.

For seasonal models, start values for $a$, $b$ and $s$ are inferred by performing a simple decomposition in trend and seasonal component using moving averages (see function `decompose`) on the start.periods first periods (a simple linear regression on the trend component is used for starting level and trend). For level/trend-models (no seasonal component), start values for $a$ and $b$ are $x[2]$ and $x[2] - x[1]$, respectively. For level-only models (ordinary exponential smoothing), the start value for $a$ is $x[1]$.

**Value**

An object of class "HoltWinters", a list with components:

- `fitted`: A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).
- `x`: The original series
- `alpha`: alpha used for filtering
- `beta`: beta used for filtering
- `gamma`: gamma used for filtering
- `coefficients`: A vector with named components $a$, $b$, $s1$, ..., $sp$ containing the estimated values for the level, trend and seasonal components
- `seasonal`: The specified seasonal parameter
- `SSE`: The final sum of squared errors achieved in optimizing
- `call`: The call used

Hypergeometric

The Hypergeometric Distribution

Description

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

Usage

dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)

Arguments

x, q
  vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.

m
  the number of white balls in the urn.

n
  the number of black balls in the urn.

k
  the number of balls drawn from the urn.

p
  probability, it must be between 0 and 1.

nn
  number of observations. If length(nn) > 1, the length is taken to be the number required.

log, log.p
  logical; if TRUE, probabilities p are given as log(p).

lower.tail
  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
The hypergeometric distribution is used for sampling without replacement. The density of this distribution with parameters $m$, $n$ and $k$ (named $Np$, $N - Np$, and $n$, respectively in the reference below) is given by

$$p(x) = \binom{m}{x} \binom{n}{k-x} / \binom{m+n}{k}$$

for $x = 0, \ldots, k$.

Note that $p(x)$ is non-zero only for $\max(0, k-n) \leq x \leq \min(k, m)$.

With $p := m/(m+n)$ (hence $Np = N \times p$ in the reference’s notation), the first two moments are mean

$$E[X] = \mu = kp$$

and variance

$$\text{Var}(X) = kp(1-p) \frac{m+n-k}{m+n-1},$$

which shows the closeness to the Binomial$(k, p)$ (where the hypergeometric has smaller variance unless $k = 1$).

The quantile is defined as the smallest value $x$ such that $F(x) \geq p$, where $F$ is the distribution function.

If one of $m, n, k$, exceeds `.Machine$integer.max`, currently the equivalent of qhyper(runif(nn), m,n,k) is used, when a binomial approximation may be considerably more efficient.

**Value**

dhyper gives the density, phyper gives the distribution function, qhyper gives the quantile function, and rhyper generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by $n$ for rhyper, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than $n$ are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Source**

dhyper computes via binomial probabilities, using code contributed by Catherine Loader (see dbinom).

phyper is based on calculating dhyper and phyper(...) / dhyper(...) (as a summation), based on ideas of Ian Smith and Morten Welinder.

qhyper is based on inversion.

rhyper is based on a corrected version of

**References**

identify.hclust

Identify Clusters in a Dendrogram

Description

identify.hclust reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

Usage

## S3 method for class 'hclust'
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL, ...)

Arguments

x an object of the type produced by hclust.
FUN (optional) function to be applied to the index numbers of the data points in a cluster (see 'Details' below).
N the maximum number of clusters to be identified.
MAXCLUSTER the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).
DEV.FUN (optional) integer scalar. If specified, the corresponding graphics device is made active before FUN is applied.
...
... further arguments to FUN.

Details

By default clusters can be identified using the mouse and an invisible list of indices of the respective data points is returned.

If FUN is not NULL, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for FUN can be specified using DEV.FUN.

The identification process is terminated by pressing any mouse button other than the first, see also identify.

Distributions for other standard distributions.

Examples

m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k))) # FALSE
## but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits = 3)
influence.measures

Value

Either a list of data point index vectors or a list of return values of FUN.

See Also

hclust, rect.hclust

Examples

## Not run:
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)

hci <- hclust(dist(iris[,1:4]))
plot(hci)
identify(hci, function(k) print(table(iris[k,5])))

# open a new device (one for dendrogram, one for bars):
dev.new() # << make that narrow (& small)
    # and *beside* 1st one
nD <- dev.cur()    # to be for the barplot
dev.set(dev.prev()) # old one for dendrogram
plot(hci)
## select subtrees in dendrogram and "see" the species distribution:
identify(hci, function(k) barplot(table(iris[k,5]), col = 2:4), DEV.FUN = nD)

## End(Not run)

influence.measures  Regression Deletion Diagnostics

Description

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

Usage

influence.measures(model)

rstandard(model, ...)
### S3 method for class 'lm'

rstandard(model, infl = lm.influence(model, do.coef = FALSE),
    sd = sqrt(deviance(model)/df.residual(model)),
    type = c("sd.1", "predictive"), ...)  

### S3 method for class 'glm'

rstandard(model, infl = influence(model, do.coef = FALSE),
    type = c("deviance", "pearson"), ...)
rstudent(model, ...)  
## S3 method for class 'lm'
rstudent(model, infl = lm.influence(model, do.coef = FALSE), 
         res = infl$wt.res, ...)  
## S3 method for class 'glm'
rstudent(model, infl = influence(model, do.coef = FALSE), ...)

dffits(model, infl = , res = )
dfbeta(model, ...)  
## S3 method for class 'lm'
dfbeta(model, infl = lm.influence(model, do.coef = TRUE), ...)
dfbetas(model, ...)  
## S3 method for class 'lm'
dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)
covratio(model, infl = lm.influence(model, do.coef = FALSE), 
         res = weighted.residuals(model))

cooks.distance(model, ...)  
## S3 method for class 'lm'
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE), 
                res = weighted.residuals(model), 
                sd = sqrt(deviance(model)/df.residual(model)), 
                hat = infl$hat, ...)  
## S3 method for class 'glm'
cooks.distance(model, infl = influence(model, do.coef = FALSE), 
                res = infl$pear.res, 
                dispersion = summary(model)$dispersion, 
                hat = infl$hat, ...)

hatvalues(model, ...)  
## S3 method for class 'lm'
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)

hat(x, intercept = TRUE)

Arguments

model an R object, typically returned by lm or glm.
infl influence structure as returned by lm.influence or influence (the latter only 
       for the glm method of rstudent and cooks.distance).
res (possibly weighted) residuals, with proper default.
sd standard deviation to use, see default.
dispersion dispersion (for glm objects) to use, see default.
hat hat values $H_{ii}$, see default.
type type of residuals for rstandard, with different options and meanings for lm and 
       glm. Can be abbreviated.
x the X or design matrix.
influence.measures

intercept should an intercept column be prepended to \( x \)?

... further arguments passed to or from other methods.

Details

The primary high-level function is `influence.measures` which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook’s distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions `dfbetas`, `dffits`, `covratio` and `cooks.distance` provide direct access to the corresponding diagnostic quantities. Functions `rstandard` and `rstudent` give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook’s distances are scaled as \( F \) rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional `infl`, `res` and `sd` arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from `lm.influence` or the generic `influence`) are already available.

Note that cases with `weights == 0` are dropped from all these functions, but that if a linear model has been fitted with `na.action = na.exclude`, suitable values are filled in for the cases excluded during fitting.

For linear models, `rstandard(*, type = "predictive")` provides leave-one-out cross validation residuals, and the “PRESS” statistic (PREdictive Sum of Squares, the same as the CV score) of model model is

\[
\text{PRESS} \leftarrow \text{sum}(\text{rstandard(model, type="pred")}^2)
\]

The function `hat()` exists mainly for S (version 2) compatibility; we recommend using `hatvalues()` instead.

Note

For `hatvalues`, `dfbeta`, and `dfbetas`, the method for linear models also works for generalized linear models.

---

**integrate**

### Integration of One-Dimensional Functions

**Description**

Adaptive quadrature of functions of one variable over a finite or infinite interval.

**Usage**

```r
integrate(f, lower, upper, ..., subdivisions = 100L,
rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)
```

**Arguments**

- `f` an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.
- `lower`, `upper` the limits of integration. Can be infinite.
- `...` additional arguments to be passed to `f`.
- `subdivisions` the maximum number of subintervals.
- `rel.tol` relative accuracy requested.
- `abs.tol` absolute accuracy requested.
- `stop.on.error` logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the message component.
- `keep.xy` unused. For compatibility with S.
- `aux` unused. For compatibility with S.

**Details**

Note that arguments after `...` must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by Wynn's Epsilon algorithm, with the basic step being Gauss–Kronrod quadrature.

`rel.tol` cannot be less than `max(50*.Machine$double.eps, 0.5e-28)` if `abs.tol <= 0`.

In R versions ≤ 3.2.x, the first entries of `lower` and `upper` were used whereas an error is signalled now if they are not of length one.
Value

A list of class "integrate" with components

- **value**: the final estimate of the integral.
- **abs.error**: estimate of the modulus of the absolute error.
- **subdivisions**: the number of subintervals produced in the subdivision process.
- **message**: "OK" or a character string giving the error message.
- **call**: the matched call.

Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

For values at a finite set of points to be a fair reflection of the behaviour of the function elsewhere, the function needs to be well-behaved, for example differentiable except perhaps for a small number of jumps or integrable singularities.

f must accept a vector of inputs and produce a vector of function evaluations at those points. The Vectorize function may be helpful to convert f to this form.

Source

Based on QUADPACK routines dqags and dqagi by R. Piessens and E. deDoncker–Kapenga, available from Netlib.

integrate(dnorm, 0, 20)
integrate(dnorm, 0, 200)
integrate(dnorm, 0, 2000)
integrate(dnorm, 0, 20000) ## fails on many systems
integrate(dnorm, 0, Inf) ## works
integrate(dnorm, 0:1, 20) #-> error!
## "silently" gave integrate(dnorm, 0, 20) in earlier versions of R

---

**interaction.plot**  
**Two-way Interaction Plot**

**Description**

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

**Usage**

interaction.plot(x.factor, trace.factor, response, fun = mean,  
type = c("l", "p", "b", "o", "c"), legend = TRUE,  
trace.label = deparse(substitute(trace.factor)),  
fixed = FALSE,  
xlab = deparse(substitute(x.factor)),  
ylab = ylabel,  
ylim = range(cells, na.rm = TRUE),  
lty = nc:1, col = 1, pch = c(1:9, 0, letters),  
xdp = NULL, leg.bg = par("bg"), leg.bty = "n",  
xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,  
...)

**Arguments**

- **x.factor**  
a factor whose levels will form the x axis.

- **trace.factor**  
another factor whose levels will form the traces.

- **response**  
a numeric variable giving the response

- **fun**  
the function to compute the summary. Should return a single real value.

- **type**  
the type of plot (see **plot.default**): lines or points or both.

- **legend**  
logical. Should a legend be included?

- **trace.label**  
overall label for the legend.

- **fixed**  
logical. Should the legend be in the order of the levels of trace.factor or in the order of the traces at their right-hand ends?

- **xlab,ylab**  
the x and y label of the plot each with a sensible default.

- **ylim**  
numeric of length 2 giving the y limits for the plot.

- **lty**  
line type for the lines drawn, with sensible default.
col

the color to be used for plotting.

pch

a vector of plotting symbols or characters, with sensible default.

xpd

determines clipping behaviour for the legend used, see par(xpd). Per default, the legend is not clipped at the figure border.

leg.bg, leg.bty

arguments passed to legend().

xtick

logical. Should tick marks be used on the x axis?

xaxt, axes, ...

graphics parameters to be passed to the plotting routines.

Details

By default the levels of x.factor are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If x.factor is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters xlab, ylab, ylim, lty, col and pch are given suitable defaults (and xlim and xaxs are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

The Interquartile Range

IQR

Description

computes interquartile range of the x values.

Usage

IQR(x, na.rm = FALSE, type = 7)

Arguments

x

a numeric vector.

na.rm

logical. Should missing values be removed?

type

an integer selecting one of the many quantile algorithms, see quantile.

Details

Note that this function computes the quartiles using the quantile function rather than following Tukey’s recommendations, i.e., IQR(x) = quantile(x, 3/4) - quantile(x, 1/4).

For normally $N(m,1)$ distributed $X$, the expected value of IQR(X) is $2 \times qnorm(3/4) = 1.3490$, i.e., for a normal-consistent estimate of the standard deviation, use IQR(x) / 1.349.

Examples

IQR(rivers)
is.empty.model  Test if a Model’s Formula is Empty

Description

R’s formula notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

Usage

`is.empty.model(x)`

Arguments

- `x`  
  A `terms` object or an object with a `terms` method.

Value

TRUE if the model is empty

See Also

`lm`, `glm`

Examples

```r
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```

isoreg  Isotonic / Monotone Regression

Description

Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

Usage

`isoreg(x, y = NULL)`

Arguments

- `x`, `y`  
  coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see `xy.coords`. 
The algorithm determines the convex minorant \( m(x) \) of the cumulative data (i.e., \( \text{cumsum}(y) \)) which is piecewise linear and the result is \( m'(x) \), a step function with level changes at locations where the convex \( m(x) \) touches the cumulative data polygon and changes slope. \( \text{as.stepfun()} \) returns a \text{stepfun} object which can be more parsimonious.

\text{Value}

\( \text{isoreg()} \) returns an object of class \text{isoreg} which is basically a list with components

- \text{x} original (constructed) abscissa values \text{x}.
- \text{y} corresponding y values.
- \text{yf} fitted values corresponding to \text{ordered} \text{x} values.
- \text{yc} cumulative y values corresponding to \text{ordered} \text{x} values.
- \text{iKnots} integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.
- \text{isOrd} logical indicating if original \text{x} values were ordered increasingly already.
- \text{ord} \text{if(!isOrd)}: integer permutation of \text{original} \text{x}.
- \text{call} the \text{call} to \text{isoreg()} used.

\text{Note}

The code should be improved to accept \text{weights} additionally and solve the corresponding weighted least squares problem.

‘Patches are welcome!’

\text{References}

\text{See Also}

the plotting method \text{plot.isoreg} with more examples; \text{isoMDS()} from the \text{MASS} package internally uses isotonic regression.

\text{Examples}

```r
require(graphics)

(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3))) # last "3", not "0"
(fi3 <- as.stepfun(ir3))

(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %.2f\n",
    1 - sum(residuals(ir4)^2) / ((10-1)*var(y4))
))

## If you are interested in the knots alone :
```
with(ir4, cbind(iKnots, yf[iKnots]))

## Example of unordered x[] with ties:
x <- sample((0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x., y))
stopifnot(all.equal(with(m, yf[iKnots]),
               as.vector(tapply(y, x., mean))))

---

**KalmanLike**

Kalman Filtering

**Description**

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

**Usage**

```r
KalmanLike(y, mod, nit = 0L, update = FALSE)
KalmanRun(y, mod, nit = 0L, update = FALSE)
KalmanSmooth(y, mod, nit = 0L)
KalmanForecast(n.ahead = 10L, mod, update = FALSE)
makeARIMA(phi, theta, Delta, kappa = 1e6, 
          SSinit = c("Gardner1980", "Rossignol2011"),
          tol = .Machine$double.eps)
```

**Arguments**

- **y**  
a univariate time series.
- **mod**  
a list describing the state-space model: see ‘Details’.
- **nit**  
the time at which the initialization is computed. nit = 0L implies that the initialization is for a one-step prediction, so Pn should not be computed at the first step.
- **update**  
if TRUE the update mod object will be returned as attribute "mod" of the result.
- **n.ahead**  
the number of steps ahead for which prediction is required.
- **phi, theta**  
numeric vectors of length ≥ 0 giving AR and MA parameters.
- **Delta**  
vector of differencing coefficients, so an ARMA model is fitted to y[t] - Delta[1]*y[t-1] - ....
- **kappa**  
the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
- **SSinit**  
a string specifying the algorithm to compute the Pn part of the state-space initialization; see ‘Details’.
- **tol**  
tolerance eventually passed to `solve.default` when SSinit = "Rossignol2011".
These functions work with a general univariate state-space model with state vector ‘a’, transitions ‘a <- T a + R e’, \( e \sim \mathcal{N}(0, \kappa Q) \) and observation equation ‘y = Z’a + eta’, \( (\text{eta} \equiv \eta), \eta \sim \mathcal{N}(0, \kappa h) \). The likelihood is a profile likelihood after estimation of \( \kappa \).

The model is specified as a list with at least components:

- T: the transition matrix
- Z: the observation coefficients
- h: the observation variance
- V: ‘RQR’
- a: the current state estimate
- P: the current estimate of the state uncertainty matrix \( Q \)
- Pn: the estimate at time \( t - 1 \) of the state uncertainty matrix \( Q \) (not updated by KalmanForecast).

KalmanSmooth is the workhorse function for tsSmooth.

makeARIMA constructs the state-space model for an ARIMA model, see also arima.

The state-space initialization has used Gardner et al’s method (SSinit = "Gardner1980"), as only method for years. However, that suffers sometimes from deficiencies when close to non-stationarity. For this reason, it may be replaced as default in the future and only kept for reproducibility reasons. Explicit specification of SSinit is therefore recommended, notably also in arima(). The "Rossignol2011" method has been proposed and partly documented by Raphael Rossignol, Univ. Grenoble, on 2011-09-20 (see PR#14682, below), and later been ported to C by Matwey V. Kornilov. It computes the covariance matrix of \( (X_{t-1}, ..., X_{t-p}, Z_t, ..., Z_{t-q}) \) by the method of difference equations (page 93 of Brockwell and Davis), apparently suggested by a referee of Gardner et al (see p.314 of their paper).

Value

For KalmanLike, a list with components Lik (the log-likelihood less some constants) and s2, the estimate of \( \kappa \).

For KalmanRun, a list with components values, a vector of length 2 giving the output of KalmanLike, resid (the residuals) and states, the contemporaneous state estimates, a matrix with one row for each observation time.

For KalmanSmooth, a list with two components. Component smooth is a \( n \) by \( p \) matrix of state estimates based on all the observations, with one row for each time. Component var is a \( n \) by \( p \) by \( p \) array of variance matrices.

For KalmanForecast, a list with components pred, the predictions, and var, the unscaled variances of the prediction errors (to be multiplied by s2).

For makeARIMA, a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

Examples

```r
## an ARIMA fit
fit3 <- arima(presidents, c(3, 0, 0))
predict(fit3, 12)
## reconstruct this
pr <- KalmanForecast(12, fit3$model)
pr$pred + fit3$coef[4]
sqrt(pr$var * fit3$sigma2)
## and now do it year by year
mod <- fit3$model
for(y in 1:3) {
  pr <- KalmanForecast(4, mod, TRUE)
  print(list(pred = pr$pred + fit3$coef["intercept"],
            se = sqrt(pr$var * fit3$sigma2)))
  mod <- attr(pr, "mod")
}
```

kernapply

*Apply Smoothing Kernel*

**Description**

kernapply computes the convolution between an input sequence and a specific kernel.

**Usage**

```
kernapply(x, ...)
```

## Default S3 method:
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'ts'
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'vector'
kernapply(x, k, circular = FALSE, ...)

## S3 method for class 'tskernel'
kernapply(x, k, circular = FALSE, ...)

kernapply(x, k, ...)
```
**Arguments**

- *x* an input vector, matrix, time series or kernel to be smoothed.
- *k* smoothing "tskernel" object.
- *circular* a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.
- ... arguments passed to or from other methods.

**Value**

A smoothed version of the input sequence.

**Note**

This uses *fft* to perform the convolution, so is fastest when *NROW(x)* is a power of 2 or some other highly composite integer.

`kernel.convolve, filter, spectrum`

**Examples**

```r
## see 'kernel' for examples
```

---

### kernel Smoothing Kernel Objects

**Description**

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects. There are `print, plot` and `[ methods for these kernel objects.

**Usage**

```r
kernel(coef, m = 2, r, name)
```

```r
df.kernel(k)
bandwidth.kernel(k)
is.tskernel(k)
```

```r
## S3 method for class 'tskernel'
plot(x, type = "h", xlab = "k", ylab = "W[k]",
     main = attr(x,"name"), ...)
```
Arguments

**coef**
the upper half of the smoothing kernel coefficients (including coefficient zero) or the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell").

**m**
the kernel dimension(s) if coef is a name. When m has length larger than one, it means the convolution of kernels of dimension m[j], for j in 1:length(m). Currently this is supported only for the named "*daniell" kernels.

**name**
the name the kernel will be called.

**r**
the kernel order for a Fejer kernel.

**k, x**
a "tskernel" object.

**type, xlab, ylab, main, ...**
arguments passed to `plot.default`.

Details

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients (as used by S-PLUS). The method allows natural indexing of kernel objects with indices in \((-m) : m\). The normalization is such that for k <- `kernel(*)`, \(\sum(k[-k\text{\ m} : k\text{\ m}])\) is one.

df.kernel returns the 'equivalent degrees of freedom' of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and bandwidth.kernel returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

Value

`kernel()` returns an object of class "tskernel" which is basically a list with the two components coef and the kernel dimension m. An additional attribute is "name".

kd[-2:2]
plot(kernel("fejer", 100, r = 6))
plot(kernel("modified.daniell", c(7,5,3)))

# Reproduce example 10.4.3 from Brockwell and Davis (1991)
spectrum(sunspot.year, kernel = kernel("daniell", c(11,7,3)), log = "no")

---

**kmeans**  

**K-Means Clustering**

**Description**

Perform k-means clustering on a data matrix.

**Usage**

```r
kmeans(x, centers, iter.max = 10, nstart = 1,  
algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",  
"MacQueen"), trace=FALSE)
```

**Arguments**

- **x**  
  numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).

- **centers**  
  either the number of clusters, say \( k \), or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in \( x \) is chosen as the initial centres.

- **iter.max**  
  the maximum number of iterations allowed.

- **nstart**  
  if centers is a number, how many random sets should be chosen?

- **algorithm**  
  character: may be abbreviated. Note that "Lloyd" and "Forgy" are alternative names for one algorithm.

- **object**  
  an R object of class "kmeans", typically the result of \( \text{ob} \leftarrow \text{kmeans}(...) \).

- **method**  
  character: may be abbreviated. "centers" causes fitted to return cluster centres (one for each input point) and "classes" causes fitted to return a vector of class assignments.

- **trace**  
  logical or integer number, currently only used in the default method ("Hartigan-Wong"): if positive (or true), tracing information on the progress of the algorithm is produced. Higher values may produce more tracing information.

... not used.
Details

The data given by \( x \) are clustered by the \( k \)-means method, which aims to partition the points into \( k \) groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use \( k \)-means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts (\( n \text{start} > 1 \)) is often recommended. In rare cases, when some of the points (rows of \( x \)) are extremely close, the algorithm may not converge in the “Quick-Transfer” stage, signalling a warning (and returning \( \text{ifault} = 4 \)). Slight rounding of the data may be advisable in that case.

For ease of programmatic exploration, \( k = 1 \) is allowed, notably returning the center and \( \text{withinss} \).

Except for the Lloyd–Forgy method, \( k \) clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

Value

\( \text{kmeans} \) returns an object of class "kmeans" which has a print and a fitted method. It is a list with at least the following components:

- \text{cluster} \text{A vector of integers (from 1:k) indicating the cluster to which each point is allocated.}
- \text{centers} \text{A matrix of cluster centres.}
- \text{totss} \text{The total sum of squares.}
- \text{withinss} \text{Vector of within-cluster sum of squares, one component per cluster.}
- \text{tot.withinss} \text{Total within-cluster sum of squares, i.e. sum(withinss).}
- \text{betweenss} \text{The between-cluster sum of squares, i.e. totss-tot.withinss.}
- \text{size} \text{The number of points in each cluster.}
- \text{iter} \text{The number of (outer) iterations.}
- \text{ifault} \text{integer: indicator of a possible algorithm problem – for experts.}

kmeans(x, 1)$withinss # trivial one-cluster, (its W.SS == ss(x))

## random starts do help here with too many clusters
## (and are often recommended anyway!):
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)

kruskal.test

Kruskal-Wallis Rank Sum Test

Description

Performs a Kruskal-Wallis rank sum test.

Usage

kruskal.test(x, ...)

## Default S3 method:
kruskal.test(x, g, ...)

## S3 method for class 'formula'
kruskal.test(formula, data, subset, na.action, ...)
kruskal.test

Arguments

- **x**: a numeric vector of data values, or a list of numeric data vectors. Non-numeric elements of a list will be coerced, with a warning.
- **g**: a vector or factor object giving the group for the corresponding elements of x. Ignored with a warning if x is a list.
- **formula**: a formula of the form response ~ group where response gives the data values and group a vector or factor of the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
- **...**: further arguments to be passed to or from methods.

Details

kruskal.test performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of x are the same in each group (sample). The alternative is that they differ in at least one.

If x is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, g is ignored, and one can simply use kruskal.test(x) to perform the test. If the samples are not yet contained in a list, use kruskal.test(list(x, ...)). Otherwise, x must be a numeric data vector, and g must be a vector or factor object of the same length as x giving the group for the corresponding elements of x.

Value

A list with class "htest" containing the following components:

- **statistic**: the Kruskal-Wallis rank sum statistic.
- **parameter**: the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- **p.value**: the p-value of the test.
- **method**: the character string "Kruskal–Wallis rank sum test".
- **data.name**: a character string giving the names of the data.

kruskal.test(Ozone ~ Month, data = airquality)

ks.test
Kolmogorov-Smirnov Tests

Description

Perform a one- or two-sample Kolmogorov-Smirnov test.

Usage

ks.test(x, y, ...,
    alternative = c("two.sided", "less", "greater"),
    exact = NULL)

Arguments

x
  a numeric vector of data values.

y
  either a numeric vector of data values, or a character string naming a cumulative
distribution function or an actual cumulative distribution function such as pnorm.
Only continuous CDFs are valid.

...  parameters of the distribution specified (as a character string) by y.

alternative
  indicates the alternative hypothesis and must be one of "two.sided" (default),
  "less", or "greater". You can specify just the initial letter of the value, but
  the argument name must be give in full. See 'Details' for the meanings of the
  possible values.

exact
  NULL or a logical indicating whether an exact p-value should be computed. See
  'Details' for the meaning of NULL. Not available in the two-sample case for a
  one-sided test or if ties are present.
Details

If \( y \) is numeric, a two-sample test of the null hypothesis that \( x \) and \( y \) were drawn from the same continuous distribution is performed.

Alternatively, \( y \) can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample test is carried out of the null that the distribution function which generated \( x \) is distribution \( y \) with parameters specified by \ldots

The presence of ties always generates a warning, since continuous distributions do not generate them. If the ties arose from rounding the tests may be approximately valid, but even modest amounts of rounding can have a significant effect on the calculated statistic.

Missing values are silently omitted from \( x \) and (in the two-sample case) \( y \).

The possible values "two.sided", "less" and "greater" of alternative specify the null hypothesis that the true distribution function of \( x \) is equal to, not less than or not greater than the hypothesized distribution function (one-sample case) or the distribution function of \( y \) (two-sample case), respectively. This is a comparison of cumulative distribution functions, and the test statistic is the maximum difference in value, with the statistic in the "greater" alternative being

\[
D^+ = \max_u [F_X(u) - F_Y(u)].
\]

Thus in the two-sample case alternative = "greater" includes distributions for which \( x \) is stochastically smaller than \( y \) (the CDF of \( x \) lies above and hence to the left of that for \( y \)), in contrast to \texttt{t.test} or \texttt{wilcox.test}.

Exact p-values are not available for the two-sample case if one-sided or in the presence of ties. If \texttt{exact} = \texttt{NULL} (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case and \textit{there are no ties}, and if the product of the sample sizes is less than 10000 in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia, Tsang & Wang (2003) (but not using the optional approximation in the right tail, so this can be slow for small p-values). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a single-sample test is used, the parameters specified in \ldots must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in \texttt{ks.test}.

Value

A list with class "htest" containing the following components:

- \texttt{statistic} the value of the test statistic.
- \texttt{p.value} the p-value of the test.
- \texttt{alternative} a character string describing the alternative hypothesis.
- \texttt{method} a character string indicating what type of test was performed.
- \texttt{data.name} a character string giving the name(s) of the data.

Source

The two-sided one-sample distribution comes \textit{via} Marsaglia, Tsang and Wang (2003).

*shapiro.test* which performs the Shapiro-Wilk test for normality.

Examples

```r
require(graphics)
x <- rnorm(50)
y <- runif(30)
# Do x and y come from the same distribution?
ks.test(x, y)
# Does x come from a shifted gamma distribution with shape 3 and rate 2?
ks.test(x+2, "pgamma", 3, 2) # two-sided, exact
ks.test(x+2, "pgamma", 3, 2, exact = FALSE)
ks.test(x+2, "pgamma", 3, 2, alternative = "gr")

# test if x is stochastically larger than x2
x2 <- rnorm(50, -1)
plot(ecdf(x), xlim = range(c(x, x2)))
plot(ecdf(x2), add = TRUE, lty = "dashed")
t.test(x, x2, alternative = "g")
wilcox.test(x, x2, alternative = "g")
ks.test(x, x2, alternative = "l")
```

ksmooth

**Kernel Regression Smoother**

Description

The Nadaraya–Watson kernel regression estimate.

Usage

```r
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
         range.x = range(x),
         n.points = max(100L, length(x)), x.points)
```

Arguments

- `x`:
  input x values. Long vectors are supported.

- `y`:
  input y values. Long vectors are supported.

- `kernel`:
  the kernel to be used. Can be abbreviated.

- `bandwidth`:
  the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at ±0.25*bandwidth.
range.x  the range of points to be covered in the output.
n.points  the number of points at which to evaluate the fit.
x.points  points at which to evaluate the smoothed fit. If missing, n.points are chosen uniformly to cover range.x. Long vectors are supported.

Value

A list with components

x  values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
y  fitted values corresponding to x.

Note

This function was implemented for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages such as KernSmooth.

Examples

```
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth = 2), col = 2)
  lines(ksmooth(speed, dist, "normal", bandwidth = 5), col = 3)
})
```

---

**lag**  
Lag a Time Series

Description

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

lag is a generic function; this page documents its default method.

Usage

```
lag(x, ...)
```

## Default S3 method:
```
lag(x, k = 1, ...)
```

Arguments

x  A vector or matrix or univariate or multivariate time series
k  The number of lags (in units of observations).
...  further arguments to be passed to or from methods.
Details

Vector or matrix arguments \( x \) are given a \texttt{tsp} attribute via \texttt{hasTsp}.

Value

A time series object with the same class as \( x \).

Note

Note the sign of \( k \): a series lagged by a positive \( k \) starts earlier.

References

See Also

diff, deltat

Examples

\begin{verbatim}
lag(ldeaths, 12) # starts one year earlier
\end{verbatim}

\begin{verbatim}
lag.plot
\end{verbatim}

Description

Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

Usage

\begin{verbatim}
lag.plot(x, lags = 1, layout = \texttt{NULL}, set.lags = 1:lags, 
main = \texttt{NULL}, asp = 1, 
diag = \texttt{TRUE}, diag.col = ”gray”, type = ”p”, oma = \texttt{NULL}, 
ask = \texttt{NULL}, do.lines = (n <= 150), labels = do.lines, 
...)
\end{verbatim}

Arguments

\begin{verbatim}
x time-series (univariate or multivariate)
lag number of lag plots desired, see arg \texttt{set.lags}.
layout the layout of multiple plots, basically the \texttt{mfrow par()} argument. The default uses about a square layout (see \texttt{n2mfrow} such that all plots are on one page.
set.lags vector of positive integers allowing specification of the set of lags used; defaults to 1:lags.
main character with a main header title to be done on the top of each page.
asp Aspect ratio to be fixed, see \texttt{plot.default}.
\end{verbatim}
lag.plot

- diag: logical indicating if the x=y diagonal should be drawn.
- diag.col: color to be used for the diagonal if(diag).
- type: plot type to be used, but see plot.ts about its restricted meaning.
- oma: outer margins, see par.
- ask: logical or NULL; if true, the user is asked to confirm before a new page is started.
- do.lines: logical indicating if lines should be drawn.
- labels: logical indicating if labels should be used.
- ...: Further arguments to plot.ts. Several graphical parameters are set in this function and so cannot be changed: these include xlab, ylab, mgp, col.lab and font.lab: this also applies to the arguments xy.labels and xy.lines.

Details

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, par(mfrow) and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If ask = NULL, par(ask = TRUE) will be called if more than one page of plots is to be produced and the device is interactive.

Note

It is more flexible and has different default behaviour than the S version. We use main = instead of head = for internal consistency.

Author(s)

Martin Maechler

See Also

plot.ts which is the basic work horse.

Examples

require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main = "Average Temperatures in New Haven")

## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
         main = "New Haven Temperatures", col.main = "blue")

## Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lags = 3)

## no lines for long series:
lag.plot(sqrt(sunspots), set = c(1:4, 9:12), pch = ".", col = "gold")
Robust Line Fitting

Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Currently the initial median-median line is *not* iterated (as opposed to Tukey’s “resistant line” in the references.

Usage

```r
line(x, y, iter = 1)
```

Arguments

- `x, y` the arguments can be any way of specifying x-y pairs. See `xy.coords`.
- `iter` positive integer specifying the number of “polishing” iterations. Note that this was hard coded to 1 in R versions before 3.5.0, and more importantly that such simple iterations may not converge, see Siegel’s 9-point example.

Details

Cases with missing values are omitted.

Contrary to the references where the data is split in three (almost) equally sized groups with symmetric sizes depending on n and n \%\% 3 and computes medians inside each group, the `line()` code splits into three groups using all observations with `x[.] <= q1` and `x[.] >= q2`, where `q1, q2` are (a kind of) quantiles for probabilities \( p = 1/3 \) and \( p = 2/3 \) of the form \((x[j1]+x[j2])/2\) where \( j1 = \text{floor}(p*(n-1)) \) and \( j2 = \text{ceiling}(p(n-1)) \), \( n = \text{length}(x) \).

Long vectors are not supported yet.

Value

An object of class “tukeyline”.

Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

Emerson, J. D. and Hoaglin, D. C. (1983). Resistant Lines for \( y \) versus \( x \). Chapter 5 of *Understanding Robust and Exploratory Data Analysis*, eds. David C. Hoaglin, Frederick Mosteller and John W. Tukey. Wiley.

See Also

There are alternatives for robust linear regression more robust and more (statistically) efficient, see \texttt{rlm()} from \texttt{MASS}, or \texttt{lmrob()} from \texttt{robustbase}.

Examples

```r
require(graphics)

plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))

## Andrew Siegel's pathological 9-point data, y-values multiplied by 3:
d.AS <- data.frame(x = c(-4:3, 12), y = 3*c(rep(0,6), -5, 5, 1))
c.AS <- with(d.AS, t(sapply(1:10,
    function(it) line(x,y, iter=it)$coefficients)))
dimnames(c.AS) <- list(paste("it =", format(1:10)), c("intercept","slope"))
c.AS
## iterations started to oscillate, repeating iteration 7,8 indefinitely
```

\texttt{listof} \hspace{1cm} \textit{A Class for Lists of (Parts of) Model Fits}

\textbf{Description}

Class "\texttt{listof}" is used by \texttt{aov} and the "\texttt{lm}" method of \texttt{alias} for lists of model fits or parts thereof. It is simply a list with an assigned class to control the way methods, especially printing, act on it.

It has a \texttt{coef} method in this package (which returns an object of this class), and \texttt{[} and \texttt{print} methods in package \texttt{base}.

\texttt{lm} \hspace{1cm} \textit{Fitting Linear Models}

\textbf{Description}

\texttt{lm} is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although \texttt{aov} may provide a more convenient interface for these).

\textbf{Usage}

```r
lm(formula, data, subset, weights, na.action,
    method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE,
    singular.ok = TRUE, contrasts = NULL, offset, ...)
```
Arguments

- formula: an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’.
- data: an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which lm is called.
- subset: an optional vector specifying a subset of observations to be used in the fitting process.
- weights: an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector. If non-NULL, weighted least squares is used with weights weights (that is, minimizing sum(w*e^2)); otherwise ordinary least squares is used. See also ‘Details’.
- na.action: a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Another possible value is NULL, no action. Value na.exclude can be useful.
- method: the method to be used; for fitting, currently only method = "qr" is supported; method = "model.frame" returns the model frame (the same as with model = TRUE, see below).
- model, x, y, qr: logicals. If TRUE the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.
- singular.ok: logical. If FALSE (the default in S but not in R) a singular fit is an error.
- contrasts: an optional list. See the contrasts.arg of model.matrix.default.
- offset: this can be used to specify an a priori known component to be included in the linear predictor during fitting. This should be NULL or a numeric vector of length equal to the number of cases. One or more offset terms can be included in the formula instead or as well, and if more than one are specified their sum is used. See model.offset.
- ... additional arguments to be passed to the low level regression fitting functions (see below).

Details

Models for lm are specified symbolically. A typical model has the form response ~ terms where response is the (numeric) response vector and terms is a series of terms which specifies a linear predictor for response. A terms specification of the form first + second indicates all the terms in first together with all the terms in second with duplicates removed. A specification of the form first:second indicates the set of terms obtained by taking the interactions of all terms in first with all terms in second. The specification first*second indicates the cross of first and second. This is the same as first + second + first:second.

If the formula includes an offset, this is evaluated and subtracted from the response.

If response is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See model.matrix for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a terms object as the formula (see aov and demo(glm.vr) for an example).
A formula has an implied intercept term. To remove this use either \( y \sim x - 1 \) or \( y \sim 0 + x \). See formula for more details of allowed formulae.

Non-NULL weights can be used to indicate that different observations have different variances (with the values in weights being inversely proportional to the variances); or equivalently, when the elements of weights are positive integers \( w_i \), that each response \( y_i \) is the mean of \( w_i \) unit-weight observations (including the case that there are \( w_i \) observations equal to \( y_i \) and the data have been summarized). However, in the latter case, notice that within-group variation is not used. Therefore, the sigma estimate and residual degrees of freedom may be suboptimal; in the case of replication weights, even wrong. Hence, standard errors and analysis of variance tables should be treated with care.

\texttt{lm} calls the lower level functions \texttt{lm.fit}, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of weights, subset and offset are evaluated in the same way as variables in formula, that is first in data and then in the environment of formula.

\section*{Value}

\texttt{lm} returns an object of \texttt{class} "\texttt{lm}\" or for multiple responses of class \texttt{c("mlm", "\texttt{lm}\")}.

The functions \texttt{summary} and \texttt{anova} are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions \texttt{coefficients}, \texttt{effects}, \texttt{fitted.values} and \texttt{residuals} extract various useful features of the value returned by \texttt{lm}.

An object of class "\texttt{lm}\" is a list containing at least the following components:

- \texttt{coefficients} a named vector of coefficients
- \texttt{residuals} the residuals, that is response minus fitted values.
- \texttt{fitted.values} the fitted mean values.
- \texttt{rank} the numeric rank of the fitted linear model.
- \texttt{weights} (only for weighted fits) the specified weights.
- \texttt{df.residual} the residual degrees of freedom.
- \texttt{call} the matched call.
- \texttt{terms} the \texttt{terms} object used.
- \texttt{contrasts} (only where relevant) the contrasts used.
- \texttt{xlevels} (only where relevant) a record of the levels of the factors used in fitting.
- \texttt{offset} the offset used (missing if none were used).
- \texttt{y} if requested, the response used.
- \texttt{x} if requested, the model matrix used.
- \texttt{model} if requested (the default), the model frame used.
- \texttt{na.action} (where relevant) information returned by \texttt{model.frame} on the special handling of NAs.

In addition, non-null fits will have components \texttt{assign}, \texttt{effects} and (unless not requested) \texttt{qr} relating to the linear fit, for use by extractor functions such as \texttt{summary} and \texttt{effects}. 
Using time series

Considerable care is needed when using `lm` with time series.

Unless `na.action = NULL`, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.) Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by `ts.intersect(..., dframe = TRUE)`, then apply a suitable `na.action` to that data frame and call `lm` with `na.action = NULL` so that residuals and fitted values are time series.

Note

Offsets specified by `offset` will not be included in predictions by `predict.lm`, whereas those specified by an offset term in the formula will be.

Author(s)

The design was inspired by the S function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

### lm.fit

**Fitter Functions for Linear Models**

**Description**

These are the basic computing engines called by `lm` used to fit linear models. These should usually *not* be used directly unless by experienced users. `.lm.fit()` is bare bone wrapper to the innermost QR-based C code, on which `glm.fit` and `lsfit` are based as well, for even more experienced users.

**Usage**

```r
lm.fit (x, y, offset = NULL, method = "qr", tol = 1e-7,
        singular.ok = TRUE, ...)
```

```r
lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
        singular.ok = TRUE, ...)
```

```r
.lm.fit(x, y, tol = 1e-7)
```

**Arguments**

- `x`  
design matrix of dimension `n * p`.
- `y`  
vector of observations of length `n`, or a matrix with `n` rows.
- `w`  
vector of weights (length `n`) to be used in the fitting process for the `wfit` functions. Weighted least squares is used with weights `w`, i.e., `sum(w * e^2)` is minimized.
- `offset`  
numeric of length `n`). This can be used to specify an *a priori* known component to be included in the linear predictor during fitting.
- `method`  
currently, only method = "qr" is supported.
- `tol`  
tolerance for the `qr` decomposition. Default is 1e-7.
- `singular.ok`  
logical. If FALSE, a singular model is an error.
- `...`  
currently disregarded.

**Value**

- a list with components (for `lm.fit` and `lm.wfit`)
  - `coefficients`  
p vector
  - `residuals`  
n vector or matrix
Description

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.
Usage

influence(model, ...)  
## S3 method for class 'lm'
influence(model, do.coef = TRUE, ...)
## S3 method for class 'glm'
influence(model, do.coef = TRUE, ...)

lm.influence(model, do.coef = TRUE)

Arguments

model an object as returned by \texttt{lm} or \texttt{glm}.
do.coef logical indicating if the changed coefficients (see below) are desired. These need \(O(n^2 p)\) computing time.
...

Details

The \texttt{influence.measures()} and other functions listed in \textbf{See Also} provide a more user oriented way of computing a variety of regression diagnostics. These all build on \texttt{lm.influence}. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in sigma and coefficients are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.) \texttt{naresid} is applied to the results and so will fill in with NAs if the fit had \texttt{na.action = na.exclude}.

Value

A list containing the following components of the same length or number of rows \(n\), which is the number of non-zero weights. Cases omitted in the fit are omitted unless a \texttt{na.action} method was used (such as \texttt{na.exclude}) which restores them.

\begin{itemize}
\item \texttt{hat} a vector containing the diagonal of the ‘hat’ matrix.
\item \texttt{coefficients} (unless \texttt{do.coef} is false) a matrix whose \(i\)-th row contains the change in the estimated coefficients which results when the \(i\)-th case is dropped from the regression. Note that aliased coefficients are not included in the matrix.
\item \texttt{sigma} a vector whose \(i\)-th element contains the estimate of the residual standard deviation obtained when the \(i\)-th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.)
\item \texttt{wt.res} a vector of \texttt{weighted} (or for class \texttt{glm} rather \texttt{deviance}) residuals.
\end{itemize}

Note

The \texttt{coefficients} returned by the R version of \texttt{lm.influence} differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures. Since these need \(O(n^2 p)\) computing time, they can be omitted by \texttt{do.coef = FALSE}.

Note that cases with weights == 0 are dropped (contrary to the situation in S).

If a model has been fitted with \texttt{na.action = na.exclude} (see \texttt{na.exclude}), cases excluded in the fit are considered here.
lm.summaries

References

See the list in the documentation for `influence.measures`.

`summary.lm` for `summary` and related methods; `influence.measures`, `hat` for the hat matrix diagonals, `dfbeta`, `dffits`, `covratio`, `cooksd`, `lm`.

Examples

```r
## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
  data = LifeCycleSavings),
  corr = TRUE)
utils::str(lmI <- lm.influence(lm.SR))

## For more "user level" examples, use example(influence.measures)
```

lm.summaries

Accessing Linear Model Fits

Description

All these functions are *methods* for class "lm" objects.

Usage

```r
## S3 method for class 'lm'
family(object, ...)

## S3 method for class 'lm'
formula(x, ...)

## S3 method for class 'lm'
residuals(object,
  type = c("working", "response", "deviance", "pearson",
           "partial"),
  ...)

## S3 method for class 'lm'
labels(object, ...)
```

Arguments

```r
object, x
  an object inheriting from class lm, usually the result of a call to lm or aov.
...
  further arguments passed to or from other methods.

  type
    the type of residuals which should be returned. Can be abbreviated.
```
Details

The generic accessor functions coef, effects, fitted and residuals can be used to extract various useful features of the value returned by lm.

The working and response residuals are ‘observed - fitted’. The deviance and pearson residuals are weighted residuals, scaled by the square root of the weights used in fitting. The partial residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized rstudent residuals, and the weighted.residuals).

How residuals treats cases with missing values in the original fit is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the residuals, whereas if na.action = na.exclude they will appear, with residual value NA. See also naresid.

The “lm” method for generic labels returns the term labels for estimable terms, that is the names of the terms with at least one estimable coefficient.

References

See Also

The model fitting function lm, anova.lm.

coef, deviance, df.residual, effects, fitted, glm for generalized linear models, influence (etc on that page) for regression diagnostics, weighted.residuals, residuals, residuals.glm, summary.lm, weights.

influence.measures for deletion diagnostics, including standardized (rstandard) and studentized (rstudent) residuals.

Examples

```r
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients

## The 2 basic regression diagnostic plots [plot.lm(.) is preferred]
plot(resid(lm.D90), fitted(lm.D90)) # Tukey-Anscombe's
abline(h = 0, lty = 2, col = "gray")
qqnorm(residuals(lm.D90))
```

loadings

Print Loadings in Factor Analysis

Description

Extract or print loadings in factor analysis (or principal components analysis).
Usage
loadings(x, ...)

## S3 method for class 'loadings'
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)

## S3 method for class 'factanal'
print(x, digits = 3, ...)

Arguments

x
an object of class "factanal" or "princomp" or the loadings component of such an object.
digits
number of decimal places to use in printing uniquenesses and loadings.
cutoff
loadings smaller than this (in absolute value) are suppressed.
sort
logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.

... further arguments for other methods, ignored for loadings.

Details

‘Loadings’ is a term from factor analysis, but because factor analysis and principal component analysis (PCA) are often conflated in the social science literature, it was used for PCA by SPSS and hence by princomp in S-PLUS to help SPSS users.

Small loadings are conventionally not printed (replaced by spaces), to draw the eye to the pattern of the larger loadings.

The print method for class "factanal" calls the "loadings" method to print the loadings, and so passes down arguments such as cutoff and sort.

The signs of the loadings vectors are arbitrary for both factor analysis and PCA.

Note

There are other functions called loadings in contributed packages which are S3 or S4 generic: the ... argument is to make it easier for this one to become a default method.

factanal, princomp

---

loess

Local Polynomial Regression Fitting

Description

Fit a polynomial surface determined by one or more numerical predictors, using local fitting.
Usage

loess(formula, data, weights, subset, na.action, model = FALSE,
span = 0.75, enp.target, degree = 2,
parametric = FALSE, drop.square = FALSE, normalize = TRUE,
family = c("gaussian", "symmetric"),
method = c("loess", "model.frame"),
control = loess.control(...), ...)

Arguments

formula a formula specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.
data an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from environment(formula), typically the environment from which loess is called.
weights optional weights for each case.
subset an optional specification of a subset of the data to be used.
na.action the action to be taken with missing values in the response or predictors. The default is given by getOption("na.action").
model should the model frame be returned?
span the parameter $\alpha$ which controls the degree of smoothing.
enp.target an alternative way to specify span, as the approximate equivalent number of parameters to be used.
degree the degree of the polynomials to be used, normally 1 or 2. (Degree 0 is also allowed, but see the ‘Note’.)
parametric should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.
drop.square for fits with more than one predictor and degree = 2, should the quadratic term be dropped for particular predictors? Terms are specified in the same way as for parametric.
normalize should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others known to be on a common scale.
family if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey’s biweight function. Can be abbreviated.
method fit the model or just extract the model frame. Can be abbreviated.
control control parameters: see loess.control.
... control parameters can also be supplied directly (if control is not specified).

Details

Fitting is done locally. That is, for the fit at point $x$, the fit is made using points in a neighbourhood of $x$, weighted by their distance from $x$ (with differences in ‘parametric’ variables being ignored when computing the distance). The size of the neighbourhood is controlled by $\alpha$ (set by span or
loess

enp.target). For \( \alpha < 1 \), the neighbourhood includes proportion \( \alpha \) of the points, and these have tricubic weighting (proportional to \( (1 - (\text{dist}/\text{maxdist})^3)^3 \)). For \( \alpha > 1 \), all points are used, with the ‘maximum distance’ assumed to be \( \alpha^{1/p} \) times the actual maximum distance for \( p \) explanatory variables.

For the default family, fitting is by (weighted) least squares. For family="symmetric" a few iterations of an M-estimation procedure with Tukey’s biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See loess.control for details.

Value

An object of class "loess".

Note

As this is based on cloess, it is similar to but not identical to the loess function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of loess is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

degree = 0, local constant fitting, is allowed in this implementation but not documented in the reference. It seems very little tested, so use with caution.

Author(s)

B. D. Ripley, based on the cloess package of Cleveland, Grosse and Shyu.

Source

References

See Also

loess.control, predict.loess.

lowess, the ancestor of loess (with different defaults!).

Examples

cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to allow extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
loess.control

Set Parameters for Loess

Description
Set control parameters for loess fits.

Usage
loess.control(surface = c("interpolate", "direct"),
              statistics = c("approximate", "exact", "none"),
              trace.hat = c("exact", "approximate"),
              cell = 0.2, iterations = 4, iterTrace = FALSE, ...)

Arguments
- **surface**: should the fitted surface be computed exactly ("direct") or via interpolation from a kd tree? Can be abbreviated.
- **statistics**: should the statistics be computed exactly, approximately or not at all? Exact computation can be very slow. Can be abbreviated.
- **trace.hat**: Only for the (default) case (surface = "interpolate", statistics = "approximate"); should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points. Can be abbreviated.
- **cell**: if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than floor(n*span*cell) points are subdivided.
- **iterations**: the number of iterations used in robust fitting, i.e. only if family is "symmetric".
- **iterTrace**: logical (or integer) determining if tracing information during the robust iterations (iterations >= 2) is produced.
- **...**: further arguments which are ignored.

Value
A list with components
- surface
- statistics
- trace.hat
- cell
- iterations
- iterTrace
with meanings as explained under ‘Arguments’.

See Also
loess
Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters location and scale.

Usage

dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
location, scale location and scale parameters.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

If location or scale are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with location = \( \mu \) and scale = \( \sigma \) has distribution function

\[
F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}
\]

and density

\[
f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{1 + e^{(x-\mu)/\sigma}^2}
\]

It is a long-tailed distribution with mean \( \mu \) and variance \( \pi^2/3\sigma^2 \).

Value

dlogis gives the density, plogis gives the distribution function, qlogis gives the quantile function, and rlogis generates random deviates.

The length of the result is determined by n for rlogis, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.
Note

qlogis(p) is the same as the well known ‘logit’ function, logit(p) = log p/(1 − p), and plogis(x) has consequently been called the ‘inverse logit’.

The distribution function is a rescaled hyperbolic tangent, plogis(x) = (1 + tanh(x/2))/2, and it is called a sigmoid function in contexts such as neural networks.

Source

[dpq]logis are calculated directly from the definitions.
rlogis uses inversion.

References

See Also

Distributions for other standard distributions.

Examples

var(rlogis(4000, 0, scale = 5))  # approximately (+/- 3)
pi^2/3 * 5^2

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which have methods for this function include: "glm", "lm", "nls" and "Arima". Packages contain methods for other classes, such as "fitdistr", "negbin" and "polr" in package MASS, "multinom" in package nnet and "gls", "gnls" "lme" and others in package nlme.

Usage

logLik(object, ...)  

## S3 method for class 'lm'
logLik(object, REML = FALSE, ...)

Arguments

object any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.

... some methods for this generic function require additional arguments.

REML an optional logical value. If TRUE the restricted log-likelihood is returned, else, if FALSE, the log-likelihood is returned. Defaults to FALSE.
Details

logLik is most commonly used for a model fitted by maximum likelihood, and some uses, e.g. by AIC, assume this. So care is needed where other fit criteria have been used, for example REML (the default for "lme").

For a "glm" fit the family does not have to specify how to calculate the log-likelihood, so this is based on using the family's aic() function to compute the AIC. For the gaussian, Gamma and inverse.gaussian families it assumed that the dispersion of the GLM is estimated and has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known. Note that this procedure does not give the maximized likelihood for "glm" fits from the Gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included. That method is only applicable to single-response fits.

Value

Returns an object of class logLik. This is a number with at least one attribute, "df" (degrees of freedom), giving the number of (estimated) parameters in the model.

There is a simple print method for "logLik" objects.

There may be other attributes depending on the method used: see the appropriate documentation. One that is used by several methods is "nobs", the number of observations used in estimation (after the restrictions if REML = TRUE).

Author(s)

José Pinheiro and Douglas Bates

fm1 <- lm(distance ~ Sex * age, Orthodont)
```
logLik(fm1)
logLik(fm1, REML = TRUE)

loglin

Fitting Log-Linear Models

Description

loglin is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

Usage

loglin(table, margin, start = rep(1, length(table)), fit = FALSE, eps = 0.1, iter = 20, param = FALSE, print = TRUE)

Arguments

table a contingency table to be fit, typically the output from table.
margin a list of vectors with the marginal totals to be fit.
(Hierarchical) log-linear models can be specified in terms of these marginal totals which give the ‘maximal’ factor subsets contained in the model. For example, in a three-factor model, list(c(1, 2), c(1, 3)) specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as '[12][13]'). The names of factors (i.e., names(dimnames(table))) may be used rather than numeric indices.

start a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in table which should be preserved in the fit. In this case, the corresponding entries in start should be zero and the others can be taken as one.

fit a logical indicating whether the fitted values should be returned.
eps maximum deviation allowed between observed and fitted margins.
iter maximum number of iterations.
param a logical indicating whether the parameter values should be returned.
print a logical. If TRUE, the number of iterations and the final deviation are printed.

Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most iter iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than eps. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with df degrees of freedom.
Note that the IPF steps are applied to the factors in the order given in margin. Hence if the model is decomposable and the order given in margin is a running intersection property ordering then IPF will converge in one iteration.

Package MASS contains loglm, a front-end to loglin which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as lm or glm.

Value

A list with the following components.

- lrt the Likelihood Ratio Test statistic.
- pearson the Pearson test statistic (X-squared).
- df the degrees of freedom for the fitted model. There is no adjustment for structural zeros.
- margin list of the margins that were fit. Basically the same as the input margin, but with numbers replaced by names where possible.
- fit An array like table containing the fitted values. Only returned if fit is TRUE.
- param A list containing the estimated parameters of the model. The ‘standard’ constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if param is TRUE.

Author(s)

Kurt Hornik

References

table.

loglm in package MASS for a user-friendly wrapper.

glm for another way to fit log-linear models.

Examples

```r
## Model of joint independence of sex from hair and eye color.
fm <- loglin(HairEyeColor, list(c(1, 2), c(1, 3), c(2, 3)))
fm
1 - pchisq(fm$lrt, fm$df)
## Model with no three-factor interactions fits well.
```
Description
Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to meanlog and standard deviation equal to sdlog.

Usage

dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)

Arguments
x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number required.
meanlog, sdlog mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details
The log normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x) - \mu)^2/2\sigma^2}$$

where $\mu$ and $\sigma$ are the mean and standard deviation of the logarithm. The mean is $E(X) = e^{\mu + 1/2\sigma^2}$, the median is $\text{med}(X) = e^{\mu}$, and the variance $\text{Var}(X) = e^{2\mu + \sigma^2}(e^{\sigma^2} - 1)$ and hence the coefficient of variation is $\sqrt{e^{\sigma^2} - 1}$ which is approximately $\sigma$ when that is small (e.g., $\sigma < 1/2$).

Value
dlnorm gives the density, plnorm gives the distribution function, qlnorm gives the quantile function, and rlnorm generates random deviates.

The length of the result is determined by n for rlnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note
The cumulative hazard $H(t) = -\log(1 - F(t))$ is -plnorm(t, r, lower = FALSE, log = TRUE).
Source

dlnorm is calculated from the definition (in ‘Details’). [pqr]lnorm are based on the relationship to the normal.

Consequently, they model a single point mass at exp(meanLog) for the boundary case sdlog = 0.

Distributions for other standard distributions, including dnorm for the normal distribution.

Examples

dlnorm(1) == dnorm(0)

lowess Scatter Plot Smoothing

Description

This function performs the computations for the LOWESS smoother which uses locally-weighted polynomial regression (see the references).

Usage

lowess(x, y = NULL, f = 2/3, iter = 3, delta = 0.01 * diff(range(x)));

Arguments

x, y vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see xy.coords.

f the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.

iter the number of ‘robustifying’ iterations which should be performed. Using smaller values of iter will make lowess run faster.

delta See ‘Details’. Defaults to 1/100th of the range of x.
Details

**lowess** is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file ‘src/appl/lowess.doc’. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the \( \text{floor}(f*n) \)th nearest neighbour, and tricubic weighting is used for \( x \) which fall within the neighbourhood.

The initial fit is done using weighted least squares. If \( \text{iter} > 0 \), further weighted fits are done using the product of the weights from the proximity of the \( x \) values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

delta is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within delta of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

Value

**lowess** returns a list containing components \( x \) and \( y \) which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function \( \text{lines} \): see the examples.

References

lines(lowess(cars), col = 2)
lines(lowess(cars, f = .2), col = 3)
legend(5, 120, c(paste("f = ", c("2/3", ".2"))), lty = 1, col = 2:3)
```

---

**ls.diag**

*Compute Diagnostics for lsfit Regression Results*

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.
Usage

ls.diag(ls.out)

Arguments

ls.out Typically the result of \texttt{lsfit()}

Value

A list with the following numeric components.

- \texttt{std.dev} The standard deviation of the errors, an estimate of $\sigma$.
- \texttt{hat} diagonal entries $h_{ii}$ of the hat matrix $H$
- \texttt{std.res} standardized residuals
- \texttt{stud.res} studentized residuals
- \texttt{cooks} Cook’s distances
- \texttt{dfits} DFITS statistics
- \texttt{correlation} correlation matrix
- \texttt{std.err} standard errors of the regression coefficients
- \texttt{cov.scaled} Scaled covariance matrix of the coefficients
- \texttt{cov.unscaled} Unscaled covariance matrix of the coefficients

References

See Also

\texttt{hat} for the hat matrix diagonals, \texttt{ls.print, lm.influence, summary.lm, anova}.

Examples

```r
##-- Using the same data as the \texttt{lm(.)} example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr = FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim = c(0, 0.11))
abline(h = 0, lty = 2, col = "lightgray")
```
ls.print

Print lsfit Regression Results

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if print.it is TRUE.

Usage

ls.print(ls.out, digits = 4, print.it = TRUE)

Arguments

- `ls.out`: Typically the result of `lsfit()`
- `digits`: The number of significant digits used for printing
- `print.it`: A logical indicating whether the result should also be printed

Value

A list with the components

- `summary`: The ANOVA table of the regression
- `coef.table`: Matrix with regression coefficients, standard errors, t- and p-values

Note

Usually you would use `summary(lm(...))` and `anova(lm(...))` to obtain similar output.

See Also

`ls.diag, lsfit`, also for examples; `lm, lm.influence` which usually are preferable.

lsfit

Find the Least Squares Fit

Description

The least squares estimate of $\beta$ in the model

$$Y = X\beta + \epsilon$$

is found.

Usage

lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07, yname = NULL)
Arguments

- **x**: a matrix whose rows correspond to cases and whose columns correspond to variables.
- **y**: the responses, possibly a matrix if you want to fit multiple left hand sides.
- **wt**: an optional vector of weights for performing weighted least squares.
- **intercept**: whether or not an intercept term should be used.
- **tolerance**: the tolerance to be used in the matrix decomposition.
- **yname**: names to be used for the response variables.

Details

If weights are specified then a weighted least squares is performed with the weight given to the \( j \)th case specified by the \( j \)th entry in \( \text{wt} \).

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

Value

A list with the following named components:

- **coef**: the least squares estimates of the coefficients in the model (\( \beta \) as stated above).
- **residuals**: residuals from the fit.
- **intercept**: indicates whether an intercept was fitted.
- **qr**: the QR decomposition of the design matrix.

References

See Also

- **lm** which usually is preferable; **ls.print, ls.diag**.

Examples

```r
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = unclass(gl(2, 10)), y = weight)
ls.print(lsD9)
```
### mad

**Median Absolute Deviation**

#### Description

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

#### Usage

```r
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE,
    low = FALSE, high = FALSE)
```

#### Arguments

- `x`: a numeric vector.
- `center`: Optionally, the centre: defaults to the median.
- `constant`: scale factor.
- `na.rm`: if `TRUE` then NA values are stripped from `x` before computation takes place.
- `low`: if `TRUE`, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
- `high`: if `TRUE`, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.

#### Details

The actual value calculated is `constant * cMedian(abs(x - center))` with the default value of `center` being `median(x)`, and `cMedian` being the usual, the ‘low’ or ‘high’ median, see the arguments description for `low` and `high` above.

The default constant = 1.4826 (approximately \(1/\Phi^{-1}(\frac{3}{4}) = 1/qnorm(3/4)\)) ensures consistency, i.e.,

\[
E[\text{mad}(X_1, \ldots, X_n)] = \sigma
\]

for \(X_i\) distributed as \(N(\mu, \sigma^2)\) and large \(n\).

If `na.rm` is `TRUE` then NA values are stripped from `x` before computation takes place. If this is not done then an NA value in `x` will cause `mad` to return NA.

#### See Also

- `IQR` which is simpler but less robust
- `median`, `var`.

#### Examples

```r
mad(c(1:9))
print(mad(c(1:9), constant = 1)) ==
mad(c(1:8, 100), constant = 1)  # = 2 ; TRUE
x <- c(1,2,3,5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant = 1),
mad(x, constant = 1, low = TRUE),
mad(x, constant = 1, high = TRUE))
```
**mahalanobis**

**Mahalanobis Distance**

**Description**

Returns the squared Mahalanobis distance of all rows in \(x\) and the vector \(\mu = \text{center}\) with respect to \(\Sigma = \text{cov}\). This is (for vector \(x\)) defined as

\[
D^2 = (x - \mu)' \Sigma^{-1} (x - \mu)
\]

**Usage**

\[
\text{mahalanobis}(x, \text{center}, \text{cov}, \text{inverted} = \text{FALSE}, ...)
\]

**Arguments**

- \(x\) vector or matrix of data with, say, \(p\) columns.
- \(\text{center}\) mean vector of the distribution or second data vector of length \(p\) or recyclable to that length. If set to \(\text{FALSE}\), the centering step is skipped.
- \(\text{cov}\) covariance matrix \((p \times p)\) of the distribution.
- \(\text{inverted}\) logical. If \(\text{TRUE}\), \(\text{cov}\) is supposed to contain the inverse of the covariance matrix.
- \(\ldots\) passed to \(\text{solve}\) for computing the inverse of the covariance matrix (if \(\text{inverted}\) is false).

**See Also**

- \(\text{cov}, \text{var}\)

**Examples**

```r
require(graphics)
ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0, 0), 1:2, S)
x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x*x))
##- Here, D^2 = usual squared Euclidean distances
Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)
density(D2, bw = 0.5), main="Squared Mahalanobis distances, n=100, p=3") ; rug(D2)
qqplot(qchisq(ppoints(100), df = 3), D2,
main = expression("Q-Q plot of Mahalanobis" * ~D^2 * " vs. quantiles of" * ~\text{chi}[3]^2))
abline(0, 1, col = 'gray')
```
make.link

Create a Link for GLM Families

Description

This function is used with the family functions in glm(). Given the name of a link, it returns a link function, an inverse link function, the derivative \( d\mu/d\eta \) and a function for domain checking.

Usage

make.link(link)

Arguments

link character; one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse".

Value

A object of class "link-glm", a list with components

linkfun Link function function(mu)
linkinv Inverse link function function(eta)
mu.eta Derivative function(eta) \( d\mu/d\eta \)
valideta function(eta)[ TRUE if eta is in the domain of linkinv ].
name a name to be used for the link

See Also

power, glm, family.

Examples

utils::str(make.link("logit"))

makepredictcall

Utility Function for Safe Prediction

Description

A utility to help model.frame.default create the right matrices when predicting from models with terms like (univariate) poly or ns.

Usage

makepredictcall(var, call)
Arguments

- `var` A variable.
- `call` The term in the formula, as a call.

Details

This is a generic function with methods for `poly`, `bs` and `ns`: the default method handles `scale`. If `model.frame.default` encounters such a term when creating a model frame, it modifies the `predvars` attribute of the terms supplied by replacing the term with one which will work for predicting new data. For example `makepredictcall.ns` adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the terms attribute of the model frame, or copy the `predvars` attribute of the terms attribute of the model frame to your `terms` object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

Value

A replacement for `call` for the `predvars` attribute of the terms.

See Also

- `model.frame`, `poly`, `scale`;
- `bs` and `ns` in package `splines`.
- `cars` for an example of prediction from a polynomial fit.

Examples

```r
require(graphics)
## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm, data.frame(height = ht)))
## see also example(cars)
## see bs and ns for spline examples.
```

Description

A class for the multivariate analysis of variance.

Usage

```r
manova(...)  
```

Arguments

- `...` Arguments to be passed to `aov`.

---

**manova**  
*Multivariate Analysis of Variance*

**Description**

A class for the multivariate analysis of variance.

**Usage**

`manova(...)`

**Arguments**

- `...` Arguments to be passed to `aov`. 

---
Details

Class "manova" differs from class "aov" in selecting a different summary method. Function manova calls aov and then add class "manova" to the result object for each stratum.

Value

See aov and the comments in ‘Details’ here.

References

See Also

aov, summary.manova, the latter containing more examples.

Examples

```r
## Set orthogonal contrasts.
op <- options(contrasts = c("contr.helmert", "contr.poly"))

## Fake a 2nd response variable
npk2 <- within(npk, foo <- rnorm(24))
(npk2.aov <- manova(cbind(yield, foo) ~ block + N*P*K, npk2))
summary(npk2.aov)

(npk2.aovE <- manova(cbind(yield, foo) ~ N*P*K + Error(block), npk2))
summary(npk2.aovE)
```

mantelhaen.test

Cochran-Mantel-Haenszel Chi-Squared Test for Count Data

Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

Usage

```r
mantelhaen.test(x, y = NULL, z = NULL,
    alternative = c("two.sided", "less", "greater"),
    correct = TRUE, exact = FALSE, conf.level = 0.95)
```

Arguments

- `x`: either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.
- `y`: a factor object with at least 2 levels; ignored if `x` is an array.
z a factor object with at least 2 levels identifying to which stratum the corresponding elements in x and y belong; ignored if x is an array.

alternative indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by K case.

correct a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by K case.

exact a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by K case.

conf.level confidence level for the returned confidence interval. Only used in the 2 by 2 by K case.

Details

If x is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA’s are not allowed. Otherwise, x, y and z must have the same length. Triples containing NA’s are removed. All variables must take at least two different values.

Value

A list with class "htest" containing the following components:

statistic Only present if no exact test is performed. In the classical case of a 2 by 2 by K table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.

parameter the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.

p.value the p-value of the test.

conf.int a confidence interval for the common odds ratio. Only present in the 2 by 2 by K case.

estimate an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by K case.

null.value the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by K case.

alternative a character string describing the alternative hypothesis. Only present in the 2 by 2 by K case.

method a character string indicating the method employed, and whether or not continuity correction was used.

data.name a character string giving the names of the data.

Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by K case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

## Agresti (1990), pages 231--237, Penicillin and Rabbits
## Investigation of the effectiveness of immediately injected or 1.5
## hours delayed penicillin in protecting rabbits against a lethal
## injection with beta-hemolytic streptococci.
Rabbits <-
array(c(0, 0, 6, 5,
6, 2, 0, 4,
5, 6, 1, 0,
2, 5, 0, 0),
dim = c(2, 2, 5),
dimnames = list(
  Delay = c("None", "1.5h"),
  Response = c("Cured", "Died"),
  Penicillin.Level = c("1/8", "1/4", "1/2", "1", "4")))
Rabbits

## Classical Mantel-Haenszel test
mantelhaen.test(Rabbits)
## => p = 0.047, some evidence for higher cure rate of immediate
## injection

## Exact conditional test
mantelhaen.test(Rabbits, exact = TRUE)
## => p = 0.040

## Exact conditional test for one-sided alternative of a higher
cure rate for immediate injection
mantelhaen.test(Rabbits, exact = TRUE, alternative = "greater")
## => p = 0.020

## UC Berkeley Student Admissions
mantelhaen.test(UCBAdmissions)
## No evidence for association between admission and gender
## when adjusted for department. However,
apply(UCBAdmissions, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
## This suggests that the assumption of homogeneous (conditional)
## odds ratios may be violated. The traditional approach would be
## using the Woolf test for interaction:
woolf <- function(x) {
  x <- x + 1 / 2
  k <- dim(x)[3]
  or <- apply(x, 3, function(x) (x[1,1]*x[2,2])/(x[1,2]*x[2,1]))
  w <- apply(x, 3, function(x) 1 / sum(1 / x))
  1 - pchisq(sum(w * (log(or) - weighted.mean(log(or), w)) ^ 2), k - 1)
}
woolf(UCBAdmissions)
## => p = 0.003, indicating that there is significant heterogeneity.
## (And hence the Mantel-Haenszel test cannot be used.)

## Job Satisfaction example.
Satisfaction <-
```
as.table(array(c(1, 2, 0, 0, 3, 3, 1, 2,
11, 17, 8, 4, 2, 3, 5, 2,

c("<5000", "5000-15000", "15000-25000", ">25000"),
"Job Satisfaction" =
c("V_D", "L_S", "M_S", "V_S"),
Gender = c("Female", "Male"))))

## (Satisfaction categories abbreviated for convenience.)
ftable(. ~ Gender + Income, Satisfaction)
## Table 7.8 in Agresti (2002), p. 288.
mantelhaen.test(Satisfaction)

mAuchly's Test of Sphericity

Description
Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

Usage
mauchly.test(object, ...)
## S3 method for class 'mlm'
mauchly.test(object, ...)
## S3 method for class 'SSD'
mauchly.test(object, Sigma = diag(nrow = p),
T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0,
idata = data.frame(index = seq_len(p)), ...)

Arguments

object object of class SSD or mlm.
Sigma matrix to be proportional to.
T transformation matrix. By default computed from M and X.
M formula or matrix describing the outer projection (see below).
X formula or matrix describing the inner projection (see below).
idata data frame describing intra-block design.
... arguments to be passed to or from other methods.
Details

Mauchly’s test test for whether a covariance matrix can be assumed to be proportional to a given matrix.

This is a generic function with methods for classes "mlm" and "SSD".

The basic method is for objects of class SSD the method for mlm objects just extracts the SSD matrix and invokes the corresponding method with the same options and arguments.

The T argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix T can be given directly or specified as the difference between two projections onto the spaces spanned by M and X, which in turn can be given as matrices or as model formulas with respect to idata (the tests will be invariant to parametrization of the quotient space M/X).

The common use of this test is in repeated measurements designs, with X = ~1. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve p, which is calculated internally as the dimension of the SSD matrix, and a couple of hidden functions in the stats namespace, namely proj which calculates projection matrices from design matrices or model formulas and Thin.row which removes linearly dependent rows from a matrix until it has full row rank.

Value

An object of class "htest"

Note

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in R.

References

See Also

SSD, anova.mlm, rWishart

Examples

```r
utils::example(SSD) # Brings in the mlmfit and reacttime objects

### traditional test of intrasubj. contrasts
mauchly.test(mlmfit, X = ~1)

### tests using intra-subject 3x2 design
idata <- data.frame(deg = gl(3, 1, 6, labels = c(0,4,8)),
                     noise = gl(2, 3, 6, labels = c("A","P")))
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata = idata)
```
Description

Perform McNemar’s chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

Usage

mcnemar.test(x, y = NULL, correct = TRUE)

Arguments

x
  either a two-dimensional contingency table in matrix form, or a factor object.
y
  a factor object; ignored if x is a matrix.
correct
  a logical indicating whether to apply continuity correction when computing the test statistic.

Details

The null is that the probabilities of being classified into cells \([i,j]\) and \([j,i]\) are the same.

If x is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both x and y must be vectors or factors of the same length. Incomplete cases are removed, vectors are coerced into factors, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if correct is TRUE.

Value

A list with class "htest" containing the following components:

statistic
  the value of McNemar’s statistic.
parameter
  the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value
  the p-value of the test.
method
  a character string indicating the type of test performed, and whether continuity correction was used.
data.name
  a character string giving the name(s) of the data.

## Presidential Approval Ratings.
## Approval of the President’s performance in office in two surveys,
## one month apart, for a random sample of 1600 voting-age Americans.
Performance <- matrix(c(794, 86, 150, 570),
                      nrow = 2,
                      dimnames = list("1st Survey" = c("Approve", "Disapprove"),
                                       "2nd Survey" = c("Approve", "Disapprove")))
Performance
mcnemar.test(Performance)
# => significant change (in fact, drop) in approval ratings
```

median

### Median Value

**Description**

Compute the sample median.

**Usage**

```r
median(x, na.rm = FALSE, ...)
```

**Arguments**

- `x` an object for which a method has been defined, or a numeric vector containing
  the values whose median is to be computed.
- `na.rm` a logical value indicating whether NA values should be stripped before the
  computation proceeds.
- `...` potentially further arguments for methods; not used in the default method.

**Details**

This is a generic function for which methods can be written. However, the default method makes
use of `is.na`, `sort` and `mean` from package `base` all of which are generic, and so the default method
will work for most classes (e.g., "Date") for which a median is a reasonable concept.

**Value**

The default method returns a length-one object of the same type as `x`, except when `x` is logical or
integer of even length, when the result will be double.

If there are no values or if `na.rm = FALSE` and there are NA values the result is NA of the same type
as `x` (or more generally the result of `x[FALSE][NA]`).

**References**

Brooks/Cole.
**medpolish**

**Description**

Fits an additive model (two-way decomposition) using Tukey's median polish procedure.

**Usage**

```r
medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE, na.rm = FALSE)
```

**Arguments**

- `x`: a numeric matrix.
- `eps`: real number greater than 0. A tolerance for convergence: see ‘Details’.
- `maxiter`: the maximum number of iterations
- `trace.iter`: logical. Should progress in convergence be reported?
- `na.rm`: logical. Should missing values be removed?

**Details**

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than `eps` or until there have been `maxiter` iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if `trace.iter` is TRUE. If `na.rm` is FALSE the presence of any NA value in `x` will cause an error, otherwise NA values are ignored.

`medpolish` returns an object of class `medpolish` (see below). There are printing and plotting methods for this class, which are invoked via the generics `print` and `plot`.

**Value**

An object of class `medpolish` with the following named components:

- `overall`: the fitted constant term.
- `row`: the fitted row effects.
- `col`: the fitted column effects.
- `residuals`: the residuals.
- `name`: the name of the dataset.
References

See Also

`median`; `aov` for a *mean* instead of *median* decomposition.

Examples

```r
require(graphics)

## Deaths from sport parachuting; from ABC of EDA, p.224:
deaths <-
  rbind(c(14,15,14),
        c( 7, 4, 7),
        c( 8, 2,10),
        c(15, 9,10),
        c( 0, 2, 0))
dimnames(deaths) <- list(c("1-24", "25-74", "75-199", "200++", "NA"),
                          paste(1973:1975))
deaths <- medpolish(deaths)
plot(med.d)
## Check decomposition:
all(deaths ==
    med.d$overall + outer(med.d$rownames, med.d$colnames, "+") + med.d$residuals)
```

---

**model.extract**

*Extract Components from a Model Frame*

**Description**

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

**Usage**

```r
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

**Arguments**

- `frame`, `x`, `data` A model frame.
- `component` literal character string or name. The name of a component to extract, such as "weights", "subset".
- `type` One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double".
Details

`model.extract` is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the `etastart` and `mustart` components of a `glm` fit.

`model.offset` and `model.response` are equivalent to `model.extract(, "offset")` and `model.extract(, "response")` respectively. `model.offset` sums any terms specified by `offset` terms in the formula or by `offset` arguments in the call producing the model frame: it does check that the offset is numeric.

`model.weights` is slightly different from `model.frame(, "weights")` in not naming the vector it returns.

Value

The specified component of the model frame, usually a vector.

See Also

`model.frame`, `offset`

Examples

```r
a <- model.frame(cbind(ncases,ncontrols) ~ agegp + tobgp + alcgp, data = esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp + tobgp + alcgp,
data = esoph, weights = ncases+ncontrols)
model.response(a)
model.extract(a, "weights")

a <- model.frame(cbind(ncases,ncontrols) ~ agegp,
something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)
```

---

**model.frame**  
*Extracting the Model Frame from a Formula or Fit*

Description

`model.frame` (a generic function) and its methods return a `data.frame` with the variables needed to use `formula` and any ... arguments.

Usage

```r
model.frame(formula, ...)
```

## Default S3 method:
```r
model.frame(formula, data = NULL,
subsets = NULL, data = na.fail,
drop.unused.levels = FALSE, xlev = NULL, ...)
```
## S3 method for class 'aovlist'
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm'
model.frame(formula, ...)

## S3 method for class 'lm'
model.frame(formula, ...)

get_all_vars(formula, data, ...)

### Arguments

- **formula**: a model formula or terms object or an R object.
- **data**: a data.frame, list or environment (or object coercible by as.data.frame to a data.frame), containing the variables in formula. Neither a matrix nor an array will be accepted.
- **subset**: a specification of the rows to be used: defaults to all rows. This can be any valid indexing vector (see [.data.frame) for the rows of data or if that is not supplied, a data frame made up of the variables used in formula.
- **na.action**: how NAs are treated. The default is first, any na.action attribute of data, second a na.action setting of options, and third na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Another possible value is NULL.
- **drop.unused.levels**: should factors have unused levels dropped? Defaults to FALSE.
- **xlev**: a named list of character vectors giving the full set of levels to be assumed for each factor.
- **...**: for model.frame methods, a mix of further arguments such as data, na.action, subset to pass to the default method. Any additional arguments (such as offset and weights or other named arguments) which reach the default method are used to create further columns in the model frame, with parenthesised names such as "(offset)". For get_all_vars, further named columns to include in the model frame.

### Details

Exactly what happens depends on the class and attributes of the object formula. If this is an object of fitted-model class such as "lm", the method will either return the saved model frame used when fitting the model (if any, often selected by argument model = TRUE) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class "lqs" from package MASS if no other arguments are supplied.

The rest of this section applies only to the default method.

If either formula or data is already a model frame (a data frame with a "terms" attribute) and the other is missing, the model frame is returned. Unless formula is a terms object, as.formula and then terms is called on it. (If you wish to use the keep.order argument of terms.formula, pass a terms object rather than a formula.)

Row names for the model frame are taken from the data argument if present, then from the names of the response in the formula (or rownames if it is a matrix), if there is one.

All the variables in formula, subset and in ... are looked for first in data and then in the environment of formula (see the help for formula() for further details) and collected into a data
frame. Then the subset expression is evaluated, and it is used as a row index to the data frame. Then the `na.action` function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the `drop.unused.levels` and `xlev` arguments: if `xlev` specifies a factor and a character variable is found, it is converted to a factor (as from R 2.10.0).

Unless `na.action = NULL`, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that all the variables in the formula are included in the data frame, even those preceded by `-`. Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

`get_all_vars` returns a `data.frame` containing the variables used in `formula` plus those specified in `...` which are recycled to the number of data frame rows. Unlike `model.frame.default`, it returns the input variables and not those resulting from function calls in `formula`.

Value

A `data.frame` containing the variables used in `formula` plus those specified in `...`. It will have additional attributes, including "terms" for an object of class "terms" derived from `formula`, and possibly "na.action" giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by `na.pass`).

References

See Also

`model.matrix` for the 'design matrix', `formula` for formulas and `expand.model.frame` for `model.frame` manipulation.

Examples

data.class(model.frame(dist ~ speed, data = cars))

```r
# get_all_vars(): new vars are recycled (iff length matches: 50 = 2*25)
cars <- get_all_vars(sqrt(dist) ~ I(speed/2), data = cars, newVar = 2:3)
stopifnot(is.data.frame(ncars),
          identical(cars, ncars[, names(cars)]),
          ncol(ncars) == ncol(cars) + 1)
```

Description

`model.matrix` creates a design (or model) matrix, e.g., by expanding factors to a set of dummy variables (depending on the contrasts) and expanding interactions similarly.
Usage

model.matrix(object, ...)  

## Default S3 method:  
model.matrix(object, data = environment(object),  
contrasts.arg = NULL, xlev = NULL, ...)

Arguments

object an object of an appropriate class. For the default method, a model formula or a terms object.
data a data frame created with model.frame. If another sort of object, model.frame is called first.
contrasts.arg A list, whose entries are values (numeric matrices or character strings naming functions) to be used as replacement values for the contrasts replacement function and whose names are the names of columns of data containing factors.
xlev to be used as argument of model.frame if data is such that model.frame is called.
... further arguments passed to or from other methods.

Details

model.matrix creates a design matrix from the description given in terms(object), using the data in data which must supply variables with the same names as would be created by a call to model.frame(object) or, more precisely, by evaluating attr(terms(object), "variables"). If data is a data frame, there may be other columns and the order of columns is not important. Any character variables are coerced to factors. After coercion, all the variables used on the right-hand side of the formula must be logical, integer, numeric or factor.

If contrasts.arg is specified for a factor it overrides the default factor coding for that variable and any "contrasts" attribute set by C or contrasts.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula (and not in the term), so in ~ a + b + b:a the interaction will have a varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is dropped (with a warning), although interactions involving the term are retained.

Value

The design matrix for a regression-like model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the term.labels attribute of the terms structure corresponding to object.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.
model.tables

References

See Also
model.frame, model.extract, terms
sparse.model.matrix from package Matrix for creating sparse model matrices, which may be more efficient in large dimensions.

Examples

```r
ff <- log(Volume) ~ log(Height) + log(Girth)
utils::str(m <- model.frame(ff, trees))
mat <- model.matrix(ff, m)

dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts")
model.matrix(~ a + b, dd)
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum"))
model.matrix(~ a + b, dd, contrasts = list(a = "contr.sum", b = "contr.poly"))
m.orth <- model.matrix(~a+b, dd, contrasts = list(a = "contr.helmert"))
crossprod(m.orth) # m.orth is ALMOST orthogonal
```

---

**model.tables**

*Compute Tables of Results from an Aov Model Fit*

Description
Computes summary tables for model fits, especially complex aov fits.

Usage

```r
model.tables(x, ...) 
## S3 method for class 'aov'
model.tables(x, type = "effects", se = FALSE, cterms, ...)

## S3 method for class 'aovlist'
model.tables(x, type = "effects", se = FALSE, ...)
```

Arguments

- **x**: a model object, usually produced by aov
- **type**: type of table: currently only "effects" and "means" are implemented. Can be abbreviated.
- **se**: should standard errors be computed?
- **ctermes**: A character vector giving the names of the terms for which tables should be computed. The default is all tables.
- **...**: further arguments passed to or from other methods.
Details

For type = "effects" give tables of the coefficients for each term, optionally with standard errors.
For type = "means" give tables of the mean response for each combinations of levels of the factors in a term.
The "aov" method cannot be applied to components of a "aovlist" fit.

Value

An object of class "tables.aov", as list which may contain components

tables A list of tables for each requested term.
n The replication information for each term.
se Standard error information.

Warning

The implementation is incomplete, and only the simpler cases have been tested thoroughly.
Weighted aov fits are not supported.

See Also

aov, proj, replications, TukeyHSD, se.contrast

Examples

options(contrasts = c("contr.helmert", "contr.treatment"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
model.tables(npk.aov, "means", se = TRUE)

## as a test, not particularly sensible statistically
npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
model.tables(npk.aovE, se = TRUE)
model.tables(npk.aovE, "means")

monthplot

Plot a Seasonal or other Subseries from a Time Series

Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

Usage

monthplot(x, ...)

## S3 method for class 'stl'
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal", ...)

## S3 method for class 'StructTS'
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)

## S3 method for class 'ts'
monthplot(x, labels = NULL, times = time(x), phase = cycle(x),
ylab = deparse(substitute(x)), ...)

## Default S3 method:
monthplot(x, labels = 1L:12L,
ylab = deparse(substitute(x)),
times = seq_along(x),
phase = (times - 1L)%%length(labels) + 1L, base = mean,
axes = TRUE, type = c("l", "h"), box = TRUE,
add = FALSE,
col = par("col"), lty = par("lty"), lwd = par("lwd"),
col.base = col, lty.base = lty, lwd.base = lwd, ...)

Arguments

x        Time series or related object.
labels   Labels to use for each ‘season’.
ylab     y label.
times    Time of each observation.
phase    Indicator for each ‘season’.
base     Function to use for reference line for subseries.
choice   Which series of an stl or StructTS object?
...      Arguments to be passed to the default method or graphical parameters.
axes     Should axes be drawn (ignored if add = TRUE)?
type     Type of plot. The default is to join the points with lines, and “h” is for histogram-like vertical lines.
box      Should a box be drawn (ignored if add = TRUE)?
add      Should thus just add on an existing plot.
col, lty, lwd Graphics parameters for the series.
col.base, lty.base, lwd.base Graphics parameters for the segments used for the reference lines.

Details

These functions extract subseries from a time series and plot them all in one frame. The ts, stl, and StructTS methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the labels are not given but the phase is given, then the labels default to the unique values of the phase. If both are given, then the phase values are assumed to be indices into the labels array, i.e., they should be in the range from 1 to length(labels).

Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.
mood.test

Author(s)
Duncan Murdoch

References

```

---

mood.test

*Mood Two-Sample Test of Scale*

Description

Performs Mood's two-sample test for a difference in scale parameters.

Usage

```r
mood.test(x, ...)  
```

## Default S3 method:
```r
mood.test(x, y,  
  alternative = c("two.sided", "less", "greater"), ...)  
```

## S3 method for class 'formula'
```r
mood.test(formula, data, subset, na.action, ...)  
```
Arguments

- **x, y**: numeric vectors of data values.
- **alternative**: indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.
- **formula**: a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
- **data**: an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
- **subset**: an optional vector specifying a subset of observations to be used.
- **na.action**: a function which indicates what should happen when the data contain NAs. Defaults togetOption("na.action").
- **...**: further arguments to be passed to or from methods.

Details

The underlying model is that the two samples are drawn from \( f(x - l) \) and \( f((x - l)/s)/s \), respectively, where \( l \) is a common location parameter and \( s \) is a scale parameter.

The null hypothesis is \( s = 1 \).

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

Value

A list with class "htest" containing the following components:

- **statistic**: the value of the test statistic.
- **p.value**: the p-value of the test.
- **alternative**: a character string describing the alternative hypothesis. You can specify just the initial letter.
- **method**: the character string "Mood two-sample test of scale".
- **data.name**: a character string giving the names of the data.

References

- `ansari.test` for another rank-based two-sample test for a difference in scale parameters; `var.test` and `bartlett.test` for parametric tests for the homogeneity in variance.
Examples

```r
## Same data as for the Ansari-Bradley test:
## Serum iron determination using Hyland control sera
mood.test(ramsay, jung.parekh)
## Compare this to ansari.test(ramsay, jung.parekh)
```

### Multinom

#### The Multinomial Distribution

**Description**

Generate multinomially distributed random number vectors and compute multinomial probabilities.

**Usage**

```r
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```

**Arguments**

- `x` vector of length `K` of integers in `0:size`.
- `n` number of random vectors to draw.
- `size` integer, say `N`, specifying the total number of objects that are put into `K` boxes in the typical multinomial experiment. For `dmultinom`, it defaults to `sum(x)`.
- `prob` numeric non-negative vector of length `K`, specifying the probability for the `K` classes; is internally normalized to sum 1. Infinite and missing values are not allowed.
- `log` logical; if TRUE, log probabilities are computed.

**Details**

If `x` is a `K`-component vector, `dmultinom(x, prob)` is the probability

\[
P(X_1 = x_1, \ldots, X_K = x_K) = C \times \prod_{j=1}^{K} \pi_j^{x_j}
\]

where `C` is the ‘multinomial coefficient’ \( C = N!/(x_1! \cdots x_K! \) and \( N = \sum_{j=1}^{K} x_j \).

By definition, each component \( X_j \) is binomially distributed as \( \text{Bin}(\text{size}, \ \text{prob}[j]) \) for \( j = 1, \ldots, K \).

The `rmultinom()` algorithm draws binomials \( X_j \) from \( \text{Bin}(n_j, P_j) \) sequentially, where \( n_1 = N \) (\( N := \text{size} \)), \( P_j = \pi_j / (\pi_j x_j + \sum_{k=1}^{j-1} \pi_k) \), and for \( j \geq 2 \), recursively, \( n_j = N - \sum_{k=1}^{j-1} X_k \) and \( P_j = \pi_j / (1 - \sum_{k=1}^{j-1} \pi_k) \).
Value

For `rmultinom()`, an integer $K \times n$ matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to `size`. Whereas the transposed result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

Note

dmultinom is currently not vectorized at all and has no C interface (API); this may be amended in the future.

See Also

Distributions for standard distributions, including dbinom which is a special case conceptually.

Examples

```r
rmultinom(10, size = 12, prob = c(0.1,0.2,0.8))
pr <- c(1,3,6,10) # normalization not necessary for generation
rmultinom(10, 20, prob = pr)
## all possible outcomes of Multinom(N = 3, K = 3)
X <- t(as.matrix(expand.grid(0:3, 0:3))); X <- X[, colSums(X) <= 3]
X <- rbind(X, 3:3 - colSums(X)); dimnames(X) <- list(letters[1:3], NULL)
X
round(apply(X, 2, function(x) dmultinom(x, prob = c(1,2,5))), 3)
```

---

### na.action  

**NA Action**

Description

Extract information on the NA action used to create an object.

Usage

```r
na.action(object, ...)
```

Arguments

- `object` any object whose NA action is given.
- `...` further arguments special methods could require.

Details

`na.action` is a generic function, and `na.action.default` its default method. The latter extracts the "na.action" component of a list if present, otherwise the "na.action" attribute.

When `model.frame` is called, it records any information on NA handling in a "na.action" attribute. Most model-fitting functions return this as a component of their result.
Value

Information from the action which was applied to object if NAs were handled specially, or NULL.

References

See Also

options("na.action"); na.omit, na.fail, also for na.exclude, na.pass.

Examples

na.action(na.omit(c(1, NA)))
Handle Missing Values in Objects

Description

These generic functions are useful for dealing with NAs in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

Usage

```r
na.fail(object, ...)  
na.omit(object, ...)  
na.exclude(object, ...)  
na.pass(object, ...)
```

Arguments

- `object`: an R object, typically a data frame
- `...`: further arguments special methods could require.

Details

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the "na.action" attribute of the result, of class "omit".

`na.exclude` differs from `na.omit` only in the class of the "na.action" attribute of the result, which is "exclude". This gives different behaviour in functions making use of `naresid` and `napredict`: when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

References

See Also

- `na.action`, `options` with argument `na.action` for setting NA actions; and `lm` and `glm` for functions using these. `na.contiguous` as alternative for time series.

Examples

```r
DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))  
na.omit(DF)  
m <- as.matrix(DF)  
na.omit(m)  
stopifnot(all(na.omit(1:3) == 1:3))  # does not affect objects with no NA's  
try(na.fail(DF))  #> Error: missing values in ...  

options("na.action")
```
naprint

Adjust for Missing Values

Description

Use missing value information to report the effects of an na.action.

Usage

naprint(x, ...)

Arguments

x
An object produced by an na.action function.

... further arguments passed to or from other methods.

Details

This is a generic function, and the exact information differs by method. naprint.omit reports the number of rows omitted: naprint.default reports an empty string.

Value

A character string providing information on missing values, for example the number.

naresid

Adjust for Missing Values

Description

Use missing value information to adjust residuals and predictions.

Usage

naresid(omit, x, ...)
napredict(omit, x, ...)

Arguments

omit an object produced by an na.action function, typically the "na.action" attribute of the result of na.omit or na.exclude.

x a vector, data frame, or matrix to be adjusted based upon the missing value information.

... further arguments passed to or from other methods.
Details

These are utility functions used to allow `predict`, `fitted` and `residuals` methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, "lm", "glm" and "nls" methods, and by further methods in packages MASS, rpart and survival. Also used for the scores returned by factanal, prcomp and princomp.

The default methods do nothing. The default method for the na.exclude action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values, predictions and weights.

Value

These return a similar object to `x`.

Note

In the early 2000s, packages rpart and survival contained versions of these functions that had an na.omit action equivalent to that now used for na.exclude.

---

NegBinomial

**The Negative Binomial Distribution**

Description

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters size and prob.

Usage

```r
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

Arguments

- `x` vector of (non-negative integer) quantiles.
- `q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `size` target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive, need not be integer.
- `prob` probability of success in each trial. $0 < \text{prob} \leq 1$.
- `mu` alternative parametrization via mean: see ‘Details’.
- `log`, `log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$. 

---

NegBinomial

**The Negative Binomial Distribution**

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters size and prob.

Usage

```r
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```
The negative binomial distribution with size = n and prob = p has density

\[ p(x) = \frac{\Gamma(x + n)}{\Gamma(n)x!} p^n (1 - p)^x \]

for \( x = 0, 1, 2, \ldots, n > 0 \) and \( 0 < p \leq 1 \).

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached. The mean is \( \mu = n(1 - p)/p \) and variance \( n(1 - p)/p^2 \).

A negative binomial distribution can also arise as a mixture of Poisson distributions with mean distributed as a gamma distribution (see \texttt{pgamma}) with scale parameter \( (1 - \text{prob})/\text{prob} \) and shape parameter size. (This definition allows non-integer values of size.)

An alternative parametrization (often used in ecology) is by the mean \( \mu \) (see above), and size, the dispersion parameter, where \( \text{prob} = \text{size}/(\text{size}+\mu) \). The variance is \( \mu + \mu^2/\text{size} \) in this parametrization.

If an element of \( x \) is not integer, the result of \texttt{dnbinom} is zero, with a warning.

The case size == 0 is the distribution concentrated at zero. This is the limiting distribution for size approaching zero, even if \( \mu \) rather than \( \text{prob} \) is held constant. Notice though, that the mean of the limit distribution is 0, whatever the value of \( \mu \).

The quantile is defined as the smallest value \( x \) such that \( F(x) \geq p \), where \( F \) is the distribution function.

\texttt{dnbinom} gives the density, \texttt{pnbinom} gives the distribution function, \texttt{qnbinom} gives the quantile function, and \texttt{rnbinom} generates random deviates.

Invalid size or prob will result in return value NaN, with a warning.

The length of the result is determined by \( n \) for \texttt{rnbinom}, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

\texttt{dnbinom} computes via binomial probabilities, using code contributed by Catherine Loader (see \texttt{dbinom}).

\texttt{pnbinom} uses \texttt{pbeta}.

\texttt{qnbinom} uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

\texttt{rnbinom} uses the derivation as a gamma mixture of Poissons, see

\textbf{See Also}

\texttt{Distributions} for standard distributions, including \texttt{dbinom} for the binomial, \texttt{dpois} for the Poisson and \texttt{dgeom} for the geometric distribution, which is a special case of the negative binomial.
Examples

```r
require(graphics)
x <- 0:11
dnnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnnbinom(0:8, size = 2, prob = 1/2) #-- theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error :
summary(1 - cumsum(dnnbinom(x, size = 2, prob = 1/2)) /
        pnnbinom(x, size = 2, prob = 1/2))

x <- 0:15
size <- (1:20)/4
persp(x, size, dnb <- outer(x, size, function(x, s) dnnbinom(x, s, prob = 0.4)),
      xlab = "x", ylab = "s", zlab = "density", theta = 150)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")
image (x, size, log10(dnb), main = paste("log ", tit, ")")
contour(x, size, log10(dnb), add = TRUE)

## Alternative parametrization
x1 <- rnbinom(500, mu = 4, size = 1)
x2 <- rnbinom(500, mu = 4, size = 10)
x3 <- rnbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
        beside = TRUE, col = c("red","blue","cyan"),
        names.arg = round(h1$breaks[-length(h1$breaks)]))
```

nextn

**Highly Composite Numbers**

Description

Nextn returns the smallest integer, greater than or equal to \( n \), which can be obtained as a product of powers of the values contained in \( \text{factors} \). Nextn is intended to be used to find a suitable length to zero-pad the argument of \( \text{fft} \) so that the transform is computed quickly. The default value for \( \text{factors} \) ensures this.

Usage

```r
nextn(n, factors = c(2,3,5))
```

Arguments

- **n**: an integer.
- **factors**: a vector of positive integer factors.

See Also

- `convolve`, `fft`
Examples

nextn(1001) # 1024
table(sapply(599:630, nextn))

nlm

Non-Linear Minimization

Description

This function carries out a minimization of the function \( f \) using a Newton-type algorithm. See the references for details.

Usage

\[
\text{nlm}(f, p, \ldots, \text{hessian} = \text{FALSE}, \text{typsize} = \text{rep}(1, \text{length}(p)), \\
\text{fscale} = 1, \text{print.level} = 0, \text{ndigit} = 12, \text{gradtol} = 1e-6, \\
\text{stepmax} = \max(1000 \times \sqrt{\sum((p/\text{typsize})^2)}, 1000), \\
\text{steptol} = 1e-6, \text{iterlim} = 100, \text{check.analyicals} = \text{TRUE})
\]

Arguments

- \( f \): the function to be minimized, returning a single numeric value. This should be a function with first argument a vector of the length of \( p \) followed by any other arguments specified by the \( \ldots \) argument.
  - If the function value has an attribute called \( \text{gradient} \) or both \( \text{gradient} \) and \( \text{hessian} \) attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. \( \text{deriv} \) returns a function with suitable \( \text{gradient} \) attribute and optionally a \( \text{hessian} \) attribute.
- \( p \): starting parameter values for the minimization.
- \( \ldots \): additional arguments to be passed to \( f \).
- \( \text{hessian} \): if \text{TRUE}, the hessian of \( f \) at the minimum is returned.
- \( \text{typsize} \): an estimate of the size of each parameter at the minimum.
- \( \text{fscale} \): an estimate of the size of \( f \) at the minimum.
- \( \text{print.level} \): this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.
- \( \text{ndigit} \): the number of significant digits in the function \( f \).
- \( \text{gradtol} \): a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in \( f \) in each direction \( p[i] \) divided by the relative change in \( p[i] \).
- \( \text{stepmax} \): a positive scalar which gives the maximum allowable scaled step length. \( \text{stepmax} \) is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. \( \text{stepmax} \) would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step.
steptol  A positive scalar providing the minimum allowable relative step length.
iterlim  a positive integer specifying the maximum number of iterations to be performed
         before the program is terminated.
check.analyticals  a logical scalar specifying whether the analytic gradients and Hessians, if they
                     are supplied, should be checked against numerical derivatives at the initial pa-
                     rameter values. This can help detect incorrectly formulated gradients or Hess-
                     sians.

Details

Note that arguments after ... must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if check.analyticals = TRUE (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

The C code for the “perturbed” cholesky, choldc() has had a bug in all R versions before 3.4.1.

From the three methods available in the original source, we always use method “1” which is line

search.

The functions supplied should always return finite (including not NA and not NaN) values: for the
function value itself non-finite values are replaced by the maximum positive value with a warning.

Value

A list containing the following components:

minimum  the value of the estimated minimum of f.
estimate the point at which the minimum value of f is obtained.
gradient  the gradient at the estimated minimum of f.
hessian  the hessian at the estimated minimum of f (if requested).
code  an integer indicating why the optimization process terminated.
       1: relative gradient is close to zero, current iterate is probably solution.
       2: successive iterates within tolerance, current iterate is probably solution.
       3: last global step failed to locate a point lower than estimate. Either
          estimate is an approximate local minimum of the function or steptol
          is too small.
       4: iteration limit exceeded.
       5: maximum step size stepmax exceeded five consecutive times. Either the
          function is unbounded below, becomes asymptotic to a finite value from
          above in some direction or stepmax is too small.
iterations  the number of iterations performed.

`optim` and `nlminb`.

`constrOptim` for constrained optimization, `optimize` for one-dimensional minimization and `uniroot` for root finding. `deriv` to calculate analytical derivatives.

For nonlinear regression, `nls` may be better.

Examples

```r
f <- function(x) sum((x-1:length(x))^2)
nlm(f, c(10,10))
nlm(f, c(10,10), print.level = 2)
utils::str(nlm(f, c(5), hessian = TRUE))

f <- function(x, a) sum((x-a)^2)
nlm(f, c(10,10), a = c(3,5))
f <- function(x, a)
{
  res <- sum((x-a)^2)
  attr(res, "gradient") <- 2*(x-a)
  res
}
nlm(f, c(10,10), a = c(3,5))

## more examples, including the use of derivatives.
## Not run: demo(nlm)
```

`nlminb` *Optimization using PORT routines*

Description

Unconstrained and box-constrained optimization using PORT routines.

For historical compatibility.

Usage

```r
nlminb(start, objective, gradient = NULL, hessian = NULL, ..., scale = 1, control = list(), lower = -Inf, upper = Inf)
```
Arguments

- **start**: numeric vector, initial values for the parameters to be optimized.
- **objective**: Function to be minimized. Must return a scalar value. The first argument to objective is the vector of parameters to be optimized, whose initial values are supplied through start. Further arguments (fixed during the course of the optimization) to objective may be specified as well (see ...).
- **gradient**: Optional function that takes the same arguments as objective and evaluates the gradient of objective at its first argument. Must return a vector as long as start.
- **hessian**: Optional function that takes the same arguments as objective and evaluates the hessian of objective at its first argument. Must return a square matrix of order length(start). Only the lower triangle is used.
- **...**: Further arguments to be supplied to objective.
- **scale**: See PORT documentation (or leave alone).
- **control**: A list of control parameters. See below for details.
- **lower, upper**: vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained.

Details

Any names of start are passed on to objective and where applicable, gradient and hessian. The parameter vector will be coerced to double.

If any of the functions returns NA or NaN this is an error for the gradient and Hessian, and such values for function evaluation are replaced by +Inf with a warning.

Value

A list with components:

- **par**: The best set of parameters found.
- **objective**: The value of objective corresponding to par.
- **convergence**: An integer code. 0 indicates successful convergence.
- **message**: A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
- **iterations**: Number of iterations performed.
- **evaluations**: Number of objective function and gradient function evaluations

Control parameters

Possible names in the control list and their default values are:

- **eval.max**: Maximum number of evaluations of the objective function allowed. Defaults to 200.
- **iter.max**: Maximum number of iterations allowed. Defaults to 150.
- **trace**: The value of the objective function and the parameters is printed every trace'th iteration. Defaults to 0 which indicates no trace information is to be printed.
- **abs.tol**: Absolute tolerance. Defaults to 0 so the absolute convergence test is not used. If the objective function is known to be non-negative, the previous default of 1e-20 would be more appropriate.
rel.tol  Relative tolerance. Defaults to 1e-10.
x.tol   X tolerance. Defaults to 1.5e-8.
xf.tol  false convergence tolerance. Defaults to 2.2e-14.
step.min, step.max Minimum and maximum step size. Both default to 1..
sing.tol singular convergence tolerance; defaults to rel.tol.
scale.init ...
diff.g  an estimated bound on the relative error in the objective function value.

## Rest lifted from optim help page

```r
nls
Nonlinear Least Squares

Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

Usage

```r
nls(formula, data, start, control, algorithm, trace, subset, weights, na.action, model, lower, upper, ...)
```

Arguments

- **formula**: a nonlinear model formula including variables and parameters. Will be coerced to a formula if necessary.
- **data**: an optional data frame in which to evaluate the variables in formula and weights. Can also be a list or an environment, but not a matrix.
- **start**: a named list or named numeric vector of starting estimates. When start is missing (and formula is not a self-starting model, see **selfStart**), a very cheap guess for start is tried (if algorithm != "plinear").
- **control**: an optional list of control settings. See **nls.control** for the names of the settable control values and their effect.
algorithm | character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references. Can be abbreviated.

trace | logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.

subset | an optional vector specifying a subset of observations to be used in the fitting process.

weights | an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.

na.action | a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit. Value na.exclude can be useful.

model | logical. If true, the model frame is returned as part of the object. Default is FALSE.

lower, upper | vectors of lower and upper bounds, replicated to be as long as start. If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.

... | Additional optional arguments. None are used at present.

Details

An nls object is a type of fitted model object. It has methods for the generic functions anova, coef, confint, deviance, df.residual, fitted, formula, logLik, predict, print, profile, residuals, summary, vcov and weights.

Variables in formula (and weights if not missing) are looked for first in data, then the environment of formula and finally along the search path. Functions in formula are searched for first in the environment of formula and then along the search path.

Arguments subset and na.action are supported only when all the variables in the formula taken from data are of the same length: other cases give a warning.

Note that the anova method does not check that the models are nested: this cannot easily be done automatically, so use with care.

Value

A list of

m | an nlsModel object incorporating the model.
data | the expression that was passed to nls as the data argument. The actual data values are present in the environment of the m component.
call | the matched call with several components, notably algorithm.
na.action | the "na.action" attribute (if any) of the model frame.
dataClasses | the "dataClasses" attribute (if any) of the "terms" attribute of the model frame.
model if model = TRUE, the model frame.
weights if weights is supplied, the weights.
convInfo a list with convergence information.
control the control list used, see the control argument.
convergence, message for an algorithm = "port" fit only, a convergence code (0 for convergence) and message.
To use these is deprecated, as they are available from convInfo now.

Warning

Do not use nls on artificial "zero-residual" data.
The nls function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form
\[ y = f(x, \theta) + \epsilon \]
(with \( \text{var}(\epsilon) > 0 \)). It fails to indicate convergence on data of the form
\[ y = f(x, \theta) \]
because the criterion amounts to comparing two components of the round-off error. If you wish to test nls on artificial data please add a noise component, as shown in the example below.
The algorithm = "port" code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

Note

Setting warnOnly = TRUE in the control argument (see nls.control) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, but not for inference.

dev
}

Pur.wt.grad <- nls( ~ weighted.MM.grad(rate, conc1, conc.1, Vm, K),
data = lisTreat, start = list(Vm = 200, K = 0.1))
rbind(coef(Pur.wt), coef(Pur.wt1), coef(Pur.wt.grad))

## In this example, there seems no advantage to providing the gradient.
## In other cases, there might be.

## The two examples below show that you can fit a model to
## artificial data with noise but not to artificial data
## without noise.

x <- 1:10
y <- 2*x + 3 # perfect fit
yeps <- y + rnorm(length(y), sd = 0.01) # added noise
nls(yeps ~ a + b*x, start = list(a = 0.12345, b = 0.54321))
## terminates in an error, because convergence cannot be confirmed:
try(nls(y - a + b*x, start = list(a = 0.12345, b = 0.54321)))

## the nls() internal cheap guess for starting values can be sufficient:

x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x))

plot(x,y, main = "nls(*), data, true function and fit, n=100")
curve(100 + 10 * exp(x / 2), col = 4, add = TRUE)
The muscle dataset in MASS is from an experiment on muscle contraction on 21 animals. The observed variables are Strip (identifier of muscle), Conc (CaCl concentration) and Length (resulting length of muscle section).

```r
utils::data(muscle, package = "MASS")
```

The non linear model considered is

\[ \text{Length} = \alpha + \beta \exp(-\text{Conc}/\theta) + \text{error} \]

where \(\theta\) is constant but \(\alpha\) and \(\beta\) may vary with Strip.

```r
with(muscle, table(Strip)) # 2, 3 or 4 obs per strip
```

We first use the plinear algorithm to fit an overall model, ignoring that \(\alpha\) and \(\beta\) might vary with Strip.

```r
musc.1 <- nls(Length ~ cbind(1, exp(-Conc/th)), muscle, 
    start = list(th = 1), algorithm = "plinear")
```

Then we use nls' indexing feature for parameters in non-linear models to use the conventional algorithm to fit a model in which \(\alpha\) and \(\beta\) vary with Strip. The starting values are provided by the previously fitted model.

```r
b <- coef(musc.1)
```

```r
musc.2 <- nls(Length ~ a[Strip] + b[Strip]*exp(-Conc/th), muscle, 
    start = list(a = rep(b[2], 21), b = rep(b[3], 21), th = b[1])
```

Arguments

- **maxiter**: A positive integer specifying the maximum number of iterations allowed.
- **tol**: A positive numeric value specifying the tolerance level for the relative offset convergence criterion.

```r
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024, 
    printEval = FALSE, warnOnly = FALSE)
```
minFactor  A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.

printEval  a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.

warnOnly  a logical specifying whether \texttt{nls()} should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of \texttt{maxiter} iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below \texttt{minFactor}.

Value

A list with exactly five components:

maxiter  
tol  
minFactor  
printEval  
warnOnly

with meanings as explained under ‘Arguments’.

\begin{tabular}{ll}
\texttt{NLSstAsymptotic} & \textit{Fit the Asymptotic Regression Model} \\
\end{tabular}

Description

Fits the asymptotic regression model, in the form $b_0 + b_1 \times \exp(-\exp(lrc) \times x)$ to the \texttt{xy} data. This can be used as a building block in determining starting estimates for more complicated models.

Usage

\texttt{NLSstAsymptotic(xy)}
**Arguments**

- `xy`  
  A `sortedXyData` object

**Value**

A numeric value of length 3 with components labelled `b0`, `b1`, and `lrc`. `b0` is the estimated intercept on the y-axis, `b1` is the estimated difference between the asymptote and the y-intercept, and `lrc` is the estimated logarithm of the rate constant.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

- `SSasymp`

**Examples**

```r
Lob.329 <- Loblolly[ Loblolly$Seed == "329", ]
print(NLSstAsymptotic(sortedXyData(expression(age),
                               expression(height),
                               Lob.329)), digits = 3)
```

---

**NLSstClosestX**

**Inverse Interpolation**

**Description**

Use inverse linear interpolation to approximate the x value at which the function represented by `xy` is equal to `yval`.

**Usage**

```r
NLSstClosestX(xy, yval)
```

**Arguments**

- `xy`  
  A `sortedXyData` object
- `yval`  
  A numeric value on the y scale

**Value**

A single numeric value on the x scale.

**Author(s)**

José Pinheiro and Douglas Bates

NLSstLfAsymptote  Horizontal Asymptote on the Left Side

Description

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of \( x \)) of the graph of \( y \) versus \( x \) from the \( xy \) object. Primarily used within initial functions for self-starting nonlinear regression models.

Usage

NLSstLfAsymptote(xy)

Arguments

xy  a sortedXyData object

Value

A single numeric value estimating the horizontal asymptote for small \( x \).

```

---

**nobs**  *Extract the Number of Observations from a Fit.*

**Description**

Extract the number of ‘observations’ from a model fit. This is principally intended to be used in computing BIC (see \texttt{AIC}).

**Usage**

\[
nobs(object, ...)
\]

### Default S3 method:

\[
nobs(object, use.fallback = FALSE, ...)
\]
Arguments

object A fitted model object.
use.fallback logical: should fallback methods be used to try to guess the value?
... Further arguments to be passed to methods.

Details

This is a generic function, with an S4 generic in package stats4. There are methods in this package
for objects of classes "lm", "glm", "nls" and "logLik", as well as a default method (which throws
an error, unless use.fallback = TRUE when it looks for weights and residuals components –
use with care!).

The main usage is in determining the appropriate penalty for BIC, but nobs is also used by the
stepwise fitting methods step, add1 and drop1 as a quick check that different fits have been fitted
to the same set of data (and not, say, that further rows have been dropped because of NAs in the
new predictors).

For lm, glm and nls fits, observations with zero weight are not included.

Value

A single number, normally an integer. Could be NA.

See Also

AIC.

Normal

The Normal Distribution

Description

Density, distribution function, quantile function and random generation for the normal distribution
with mean equal to mean and standard deviation equal to sd.

Usage

dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)

Arguments

x, q vector of quantiles.
p vector of probabilities.
n number of observations. If length(n) > 1, the length is taken to be the number
required.
mean vector of means.
sd vector of standard deviations.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \) otherwise, \( P[X > x] \).
Details

If mean or sd are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

\[ f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{(x-\mu)^2}{2\sigma^2}} \]

where \( \mu \) is the mean of the distribution and \( \sigma \) the standard deviation.

Value

dnorm gives the density, pnorm gives the distribution function, qnorm gives the quantile function, and rnorm generates random deviates.

The length of the result is determined by n for rnorm, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

For sd = 0 this gives the limit as sd decreases to 0, a point mass at mu. sd < 0 is an error and returns NaN.

Source

For pnorm, based on

For qnorm, the code is a C translation of

which provides precise results up to about 16 digits.

For rnorm, see RNG for how to select the algorithm and for references to the supplied methods.

Distributions for other standard distributions, including dlnorm for the Lognormal distribution.

Examples

```r
require(graphics)

dnorm(0) == 1/sqrt(2*pi)
dnorm(1) == exp(-1/2)/sqrt(2*pi)
dnorm(1) == 1/sqrt(2*pi*exp(1))

## Using "log = TRUE" for an extended range :
```
par(mfrow = c(2,1))
plot(function(x) dnorm(x, log = TRUE), -60, 50,
     main = "log ( Normal density )")
curve(log(dnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("dnorm(x, log=TRUE)", adj = 0)
mtext("log(dnorm(x))", col = "red", adj = 1)

plot(function(x) pnorm(x, log.p = TRUE), -50, 10,
     main = "log ( Normal Cumulative )")
curve(log(pnorm(x)), add = TRUE, col = "red", lwd = 2)
mtext("pnorm(x, log=TRUE)", adj = 0)
mtext("log(pnorm(x))", col = "red", adj = 1)

## if you want the so-called 'error function'
erf <- function(x) 2 * pnorm(x * sqrt(2)) - 1
## (see Abramowitz and Stegun 29.2.29)
## and the so-called 'complementary error function'
erfc <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)
## and the inverses
erfinv <- function (x) qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function (x) qnorm(x/2, lower = FALSE)/sqrt(2)

---

**numericDeriv**

*Evaluate Derivatives Numerically*

**Description**

numericDeriv numerically evaluates the gradient of an expression.

**Usage**

numericDeriv(expr, theta, rho = parent.frame(), dir = 1.0)

**Arguments**

- **expr**
  The expression to be differentiated. The value of this expression should be a numeric vector.

- **theta**
  A character vector of names of numeric variables used in expr.

- **rho**
  An environment containing all the variables needed to evaluate expr.

- **dir**
  A numeric vector of directions to use for the finite differences.

**Details**

This is a front end to the C function numeric_deriv, which is described in *Writing R Extensions*. The numeric variables must be of type real and not integer.

**Value**

The value of eval(expr, envir = rho) plus a matrix attribute called gradient. The columns of this matrix are the derivatives of the value with respect to the variables listed in theta.
offset

Include an Offset in a Model Formula

Description
An offset is a term to be added to a linear predictor, such as in a generalised linear model, with
known coefficient 1 rather than an estimated coefficient.

Usage
offset(object)

Arguments
object
An offset to be included in a model frame

Details
There can be more than one offset in a model formula, but – is not supported for offset terms (and
is equivalent to +).

Value
The input value.

See Also
model.offset, model.frame.
For examples see glm and Insurance in package MASS.
oneway.test

Test for Equal Means in a One-Way Layout

Description

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage

oneway.test(formula, data, subset, na.action, var.equal = FALSE)

Arguments

formula a formula of the form lhs ~ rhs where lhs gives the sample values and rhs the corresponding groups.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.

na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

var.equal a logical variable indicating whether to treat the variances in the samples as equal. If TRUE, then a simple F test for the equality of means in a one-way analysis of variance is performed. If FALSE, an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Details

If the right-hand side of the formula contains more than one term, their interaction is taken to form the grouping.

Value

A list with class "htest" containing the following components:

statistic the value of the test statistic.

parameter the degrees of freedom of the exact or approximate F distribution of the test statistic.

p.value the p-value of the test.

method a character string indicating the test performed.

data.name a character string giving the names of the data.

References

See Also

The standard t-test (t.test) as the special case for two samples; the Kruskal-Wallis test kruskal.test for a nonparametric test for equal location parameters in a one-way layout.

Examples

```r
## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
```

optim

General-purpose Optimization

Description

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

Usage

```r
optim(par, fn, gr = NULL, ..., 
method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN", 
"Brent"),
lower = -Inf, upper = Inf,
control = list(), hessian = FALSE)
optimHess(par, fn, gr = NULL, ..., control = list())
```

Arguments

- **par**: Initial values for the parameters to be optimized over.
- **fn**: A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
- **gr**: A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is NULL, a finite-difference approximation will be used. For the "SANN" method it specifies a function to generate a new candidate point. If it is NULL a default Gaussian Markov kernel is used.
- **...**: Further arguments to be passed to fn and gr.
- **method**: The method to be used. See ‘Details’. Can be abbreviated.
- **lower, upper**: Bounds on the variables for the "L-BFGS-B" method, or bounds in which to search for method "Brent".
- **control**: A list of control parameters. See ‘Details’.
- **hessian**: Logical. Should a numerically differentiated Hessian matrix be returned?
Details

Note that arguments after ... must be matched exactly.

By default `optim` performs minimization, but it will maximize if `control$fnscale` is negative. `optim$Hess` is an auxiliary function to compute the Hessian at a later stage if `hessian = TRUE` was forgotten.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd et. al. (1995) which allows box constraints, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints. This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to \( \text{temp} / \log(((t-1)/\% tmax)*tmax + \exp(1)) \), where \( t \) is the current iteration step and \( \text{temp} \) and \( tmax \) are specifiable via `control`, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Method "Brent" is for one-dimensional problems only, using `optimize()`. It can be useful in cases where `optim()` is used inside other functions where only method can be specified, such as in `mle` from package `stats4`.

Function `fn` can return `NA` or `Inf` if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of `fn`. (Except for method "L-BFGS-B" where the values should always be finite.)

`optim` can be used recursively, and for a single parameter as well as many. It also accepts a zero-length `par`, and just evaluates the function with that argument.

The `control` argument is a list that can supply any of the following components:

- `trace` Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)
- `fnscale` An overall scaling to be applied to the value of `fn` and `gr` during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on `fn(par)/fnscale`. 
parscale A vector of scaling values for the parameters. Optimization is performed on \( \text{par}/\text{parscale} \) and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value. Not used (nor needed) for method = "Brent".

deeps A vector of step sizes for the finite-difference approximation to the gradient, on \( \text{par}/\text{parscale} \) scale. Defaults to \( 1e-3 \).

maxit The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder-Mead".

For "SANN" maxit gives the total number of function evaluations: there is no other stopping criterion. Defaults to 10000.

abstol The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.

reltol Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of \( \text{reltol} \times (\text{abs(val)} + \text{reltol}) \) at a step. Defaults to \( \sqrt{\text{Machine}\$\text{double}\_\text{eps}} \), typically about \( 1e-8 \).

alpha, beta, gamma Scaling parameters for the "Nelder-Mead" method. alpha is the reflection factor (default 1.0), beta the contraction factor (0.5) and gamma the expansion factor (2.0).

REPORT The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if control$trace is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or every 100 temperatures for "SANN".

lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method. It defaults to 5.

factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is \( 1e7 \), that is a tolerance of about \( 1e-8 \).

pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

temp controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

tmax is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to \text{par} will be copied to the vectors passed to \text{fn} and \text{gr}. Note that no other attributes of \text{par} are copied over.

The parameter vector passed to \text{fn} has special semantics and may be shared between calls: the function should not change or copy it.

Value

For \text{optim}, a list with components:

\begin{itemize}
  \item \text{par} The best set of parameters found.
  \item \text{value} The value of \text{fn} corresponding to \text{par}.
  \item \text{counts} A two-element integer vector giving the number of calls to \text{fn} and \text{gr} respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to \text{fn} to compute a finite-difference approximation to the gradient.
\end{itemize}
convergence  An integer code. 0 indicates successful completion (which is always the case for "SANN" and "Brent"). Possible error codes are
1 indicates that the iteration limit maxit had been reached.
10 indicates degeneracy of the Nelder–Mead simplex.
51 indicates a warning from the "L-BFGS-B" method; see component message for further details.
52 indicates an error from the "L-BFGS-B" method; see component message for further details.

message  A character string giving any additional information returned by the optimizer, or NULL.

hessian  Only if argument hessian is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.

For optimHess, the description of the hessian component applies.

Note

optim will work with one-dimensional pars, but the default method does not work well (and will warn). Method "Brent" uses optimize and needs bounds to be available; "BFGS" often works well enough if not.

Source

The code for methods "Nelder–Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file 'opt/lbfgs BCM.shar': another version is in 'toms/778').

The code for method "SANN" was contributed by A. Trapletti.

  sq2 <- embed(sq, 2)
  sum(eurodistmat[cbind(sq2[,2], sq2[,1])])
}

genseq <- function(sq) { # Generate new candidate sequence
  idx <- seq(2, NROW(eurodistmat)-1)
  changepoints <- sample(idx, size = 2, replace = FALSE)
  tmp <- sq[changepoints[1]]
  sq[changepoints[1]] <- sq[changepoints[2]]
  ...)```
optimize

The function optimize searches the interval from lower to upper for a minimum or maximum of the function f with respect to its first argument. optimise is an alias for optimize.

Usage

optimize(f, interval, ..., lower = min(interval), upper = max(interval),
        maximum = FALSE,
        tol = .Machine$double.eps^0.25)

Arguments

f the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of maximum.
interval  a vector containing the end-points of the interval to be searched for the minimum.

... additional named or unnamed arguments to be passed to \( f \).

lower  the lower end point of the interval to be searched.

upper  the upper end point of the interval to be searched.

maximum  logical. Should we maximize or minimize (the default)?

tol  the desired accuracy.

Details

Note that arguments after ... must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If \( f \) has a continuous second derivative which is positive at the minimum (which is not at \( \text{lower} \) or \( \text{upper} \)), then convergence is superlinear, and usually of the order of about 1.324.

The function \( f \) is never evaluated at two points closer together than \( \epsilon |x_0| + (\text{tol}/3) \), where \( \epsilon \) is approximately \( \text{sqrt}(.\text{Machine}::\text{double}\text{.eps}) \) and \( x_0 \) is the final abscissa \( \text{optimize()} \$\text{minimum} \).

If \( f \) is a unimodal function and the computed values of \( f \) are always unimodal when separated by at least \( \epsilon |x| + (\text{tol}/3) \), then \( x_0 \) approximates the abscissa of the global minimum of \( f \) on the interval \( \text{lower}, \text{upper} \) with an error less than \( \epsilon |x_0| + \text{tol} \).

If \( f \) is not unimodal, then \( \text{optimize()} \) may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of \( f \) is always at \( x_1 = a + (1 - \phi)(b - a) \) where \( (a,b) = (\text{lower}, \text{upper}) \) and \( \phi = (\sqrt{5} - 1)/2 = 0.61803.. \) is the golden section ratio. Almost always, the second evaluation is at \( x_2 = a + \phi(b - a) \). Note that a local minimum inside \( [x_1, x_2] \) will be found as solution, even when \( f \) is constant in there, see the last example.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to \( f \) has special semantics and used to be shared between calls. The function should not copy it.

Value

A list with components \text{minimum} (or \text{maximum}) and \text{objective} which give the location of the minimum (or maximum) and the value of the function at that point.

Source

A C translation of Fortran code \url{http://www.netlib.org/fmm/fmin.f} (author(s) unstated) based on the Algol 60 procedure \text{localmin} given in the reference.

require(graphics)

f <- function(x, a) (x - a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower = 0, upper = 10)

## "wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }
plot(f, -2,5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20)) # doesn't see the minimum
optimize(fp, c(-7, 20)) # ok
```

order.dendrogram

### Ordering or Labels of the Leaves in a Dendrogram

Theses functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

#### Usage

```r
order.dendrogram(x)
```

#### Arguments

- `x`, `object`  
  a dendrogram (see `as.dendrogram`).
- `...`  
  additional arguments

#### Details

The indices or labels for the leaves in left to right order are retrieved.

#### Value

A vector with length equal to the number of leaves in the dendrogram is returned. From `r <- order.dendrogram()`, each element is the index into the original data (from which the dendrogram was computed).

#### Author(s)

R. Gentleman (`order.dendrogram`) and Martin Maechler (`labels.dendrogram`).
p.adjust

Adjust P-values for Multiple Comparisons

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

p.adjust(p, method = p.adjust.methods, n = length(p))

p.adjust.methods
# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
#   "fdr", "none")

Arguments

p numeric vector of p-values (possibly with NAs). Any other R is coerced by as.numeric.

method correction method. Can be abbreviated.

n number of comparisons, must be at least length(p); only set this (to non-default) when you know what you are doing!

Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH" or its alias "fdr"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the p.adjust.methods vector for the benefit of methods that need to have the method as an option and pass it on to p.adjust.

Examples

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same :
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(identical(labels(d2),
    rownames(USArrests)[order.dendrogram(d2)]))
The first four methods are designed to give strong control of the family-wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm’s method, which is also valid under arbitrary assumptions.

Hochberg’s and Hommel’s methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel’s method is more powerful than Hochberg’s, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" (aka "fdr") and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others.

Note that you can set \( n \) larger than \( \text{length}(p) \) which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

**Value**

A numeric vector of corrected p-values (of the same length as \( p \), with names copied from \( p \)).

**References**

**See Also**

`pairwise.*` functions such as `pairwise.t.test`.
Examples

```r
require(graphics)
set.seed(123)
x <- rnorm(50, mean = c(rep(0, 25), rep(3, 25)))
p <- 2*pnorm(sort(-abs(x)))

round(p, 3)
round(p.adjust(p), 3)
round(p.adjust(p, "BH"), 3)

## or all of them at once (dropping the "fdr" alias):
p.adj <- sapply(p.adjust.M, function(meth) p.adjust(p, meth))
p.adj.60 <- sapply(p.adjust.M, function(meth) p.adjust(p, meth, n = 60))
stopifnot(identical(p.adj[,"none"], p), p.adj <= p.adj.60)

## or a bit nicer:
noquote(apply(p.adj, 2, format.pval, digits = 3))

## and a graphic:
matplot(p, p.adj, ylab="p.adjust(p, meth)", type = "l", asp = 1, lty = 1:6,
main = "P-value adjustments")
legend(0.7, 0.6, p.adjust.M, col = 1:6, lty = 1:6)

## Can work with NA's:
pN <- p; iN <- c(46, 47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))

## The smallest 20 P-values all affected by the NA's :
round((pN.a / p.adj)[1:20, ] , 4)
```

pairwise.prop.test

Pairwise comparisons for proportions

Description

Calculate pairwise comparisons between pairs of proportions with correction for multiple testing

Usage

```r
pairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)
```

Arguments

- `x` Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
- `n` Vector of counts of trials; ignored if `x` is a matrix.
- `...` Additional arguments to pass to `prop.test`
Value

Object of class "pairwise.htest"

See Also

prop.test, p.adjust

Examples

```r
smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
pairwise.prop.test(smokers, patients)
```

pairwise.t.test  Pairwise t tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing

Usage

```r
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
    pool.sd = !paired, paired = FALSE,
    alternative = c("two.sided", "less", "greater"),
    ...)
```

Arguments

- **x**: response vector.
- **g**: grouping vector or factor.
- **p.adjust.method**: Method for adjusting p values (see `p.adjust`).
- **pool.sd**: switch to allow/disallow the use of a pooled SD
- **paired**: a logical indicating whether you want paired t-tests.
- **alternative**: a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". Can be abbreviated.
- **...**: additional arguments to pass to `t.test`.

Details

The pool.sd switch calculates a common SD for all groups and uses that for all comparisons (this can be useful if some groups are small). This method does not actually call `t.test`, so extra arguments are ignored. Pooling does not generalize to paired tests so pool.sd and paired cannot both be TRUE.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.
Value

Object of class “pairwise.htest”

See Also

t.test, p.adjust

Examples

attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()

pairwise.table

Tabulate p values for pairwise comparisons

Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

Usage

pairwise.table(compare.levels, level.names, p.adjust.method)

Arguments

compare.levels a function to compute (raw) p value given indices i and j.
level.names names of the group levels
p.adjust.method a character string specifying the method for multiple testing adjustment; almost always one of p.adjust.methods. Can be abbreviated.

Details

Functions that do multiple group comparisons create separate compare.levels functions (assumed to be symmetrical in i and j) and passes them to this function.

Value

Table of p values in lower triangular form.

See Also

pairwise.t.test
pairwise.wilcox.test  Pairwise Wilcoxon Rank Sum Tests

Description
Calculate pairwise comparisons between group levels with corrections for multiple testing.

Usage
pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods, 
  paired = FALSE, ...)

Arguments
x  response vector.
g  grouping vector or factor.
paired  a logical indicating whether you want a paired test.
...  additional arguments to pass to wilcox.test.

Details
Extra arguments that are passed on to wilcox.test may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting alternative to anything other than "two.sided" requires that the levels of g are ordered sensibly.

Value
Object of class "pairwise.htest"

See Also
wilcox.test, p.adjust

Examples
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties:
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")
detach()
plot.acf

Plot Autocovariance and Autocorrelation Functions

Description

Plot method for objects of class "acf".

Usage

## S3 method for class 'acf'
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
     ylim = NULL, main = NULL,
     ci.col = "blue", ci.type = c("white", "ma"),
     max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
     mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
     oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
     mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
     xpd = par("xpd"),
     cex.main = if(nser > 2) 1 else par("cex.main"),
     verbose = getOption("verbose"),
     ...)  

Arguments

x an object of class "acf".

.ci coverage probability for confidence interval. Plotting of the confidence interval
     is suppressed if .ci is zero or negative.

type the type of plot to be drawn, default to histogram like vertical lines.

xlab the x label of the plot.

ylab the y label of the plot.

ylim numeric of length 2 giving the y limits for the plot.

main overall title for the plot.

.ci.col colour to plot the confidence interval lines.

.ci.type should the confidence limits assume a white noise input or for lag k an MA(k−1)
     input? Can be abbreviated.

.max.mfrow positive integer; for multivariate x indicating how many rows and columns of
     plots should be put on one page, using par(mfrow = c(m,m)).

.ask logical; if TRUE, the user is asked before a new page is started.

.mar, oma, mgp, xpd, cex.main
     graphics parameters as in par(*), by default adjusted to use smaller than default
     margins for multivariate x only.

.verbose logical. Should R report extra information on progress?

... graphics parameters to be passed to the plotting routines.

Note

The confidence interval plotted in plot.acf is based on an uncorrelated series and should be treated
with appropriate caution. Using .ci.type = "ma" may be less potentially misleading.
See Also

acf which calls plot.acf by default.

Examples

require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start = c(1961, 1), frequency = 12)
z7 <- ts(matrix(rnorm(700), 100, 7), start = c(1961, 1), frequency = 12)
acf(z4)
acf(z7, max.mfrow = 7)  # squeeze onto 1 page
acf(z7)  # multi-page

plot.density

Plot Method for Kernel Density Estimation

Description

The plot method for density objects.

Usage

## S3 method for class 'density'
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
zero.line = TRUE, ...)

Arguments

x     a "density" object.
main, xlab, ylab, type
plotting parameters with useful defaults.
...    further plotting parameters.
zero.line logical; if TRUE, add a base line at y = 0

Value

None.

See Also
density.
plot.HoltWinters  Plot function for HoltWinters objects

Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

Usage

```r
## S3 method for class 'HoltWinters'
plot(x, predicted.values = NA, intervals = TRUE, 
     separator = TRUE, col = 1, col.predicted = 2, 
     col.intervals = 4, col.separator = 1, lty = 1, 
     lty.predicted = 1, lty.intervals = 1, lty.separator = 3, 
     ylab = "Observed / Fitted", 
     main = "Holt-Winters filtering", 
     ylim = NULL, ...)  
```

Arguments

- `x` Object of class "HoltWinters"
- `predicted.values` Predicted values as returned by `predict.HoltWinters`
- `intervals` If TRUE, the prediction intervals are plotted (default).
- `separator` If TRUE, a separating line between fitted and predicted values is plotted (default).
- `col`, `lty` Color/line type of original data (default: black solid).
- `col.predicted`, `lty.predicted` Color/line type of fitted and predicted values (default: red solid).
- `col.intervals`, `lty.intervals` Color/line type of prediction intervals (default: blue solid).
- `col.separator`, `lty.separator` Color/line type of observed/predicted values separator (default: black dashed).
- `ylab` Label of the y-axis.
- `main` Main title.
- `ylim` Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any.
- `...` Other graphics parameters.

plot.isoreg

See Also
HoltWinters, predict.HoltWinters

---

**plot.isoreg**  
*Plot Method for isoreg Objects*

**Description**

The `plot` and `lines` method for R objects of class `isoreg`.

**Usage**

```r
## S3 method for class 'isoreg'
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     main2 = "Cumulative Data and Convex Minorant",
     xlab = "x0", ylab = "x$y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...)

## S3 method for class 'isoreg'
lines(x, col = "red", lwd = 1.5,
      do.points = FALSE, cex = 1.5, pch = 13, ...)
```

**Arguments**

- `x`: an `isoreg` object.
- `plot.type`: character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit. Can be abbreviated.
- `main`: main title of plot, see `title`.
- `main2`: title for second (cumulative) plot.
- `xlab`, `ylab`: x- and y- axis annotation.
- `par.fit`: a list of arguments (for `points` and `lines`) for drawing the fit.
- `mar`, `mgp`: graphical parameters, see `par`, mainly for the case of two plots.
- `grid`: logical indicating if grid lines should be drawn. If true, `grid()` is used for the first plot, where as vertical lines are drawn at ‘touching’ points for the cumulative plot.
- `do.points`: for `lines()`: logical indicating if the step points should be drawn as well (and as they are drawn in `plot()`).
- `col`, `lwd`, `cex`, `pch`: graphical arguments for `lines()`, where `cex` and `pch` are only used when `do.points` is TRUE.
- `...`: further arguments passed to and from methods.
plot.lm

Plot Diagnostics for an lm Object

Description

Six plots (selectable by which) are currently available: a plot of residuals against fitted values, a Scale-Location plot of $\sqrt{|residuals|}$ against fitted values, a Normal Q-Q plot, a plot of Cook’s distances versus row labels, a plot of residuals against leverages, and a plot of Cook’s distances against leverage/(1-leverage). By default, the first three and 5 are provided.

Usage

## S3 method for class 'lm'
plot(x, which = c(1:3, 5),
caption = list("Residuals vs Fitted", "Normal Q-Q", 
   "Scale-Location", "Cook's distance", 
   "Residuals vs Leverage",
   expression("Cook's dist vs Leverage " * h[ii] / (1 - h[ii]))),
panel = if(add.smooth) panel.smooth else points,
sub.caption = NULL, main = "",
ask = prod(par("mfcol")) < length(which) && dev.interactive(),
...
, id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qline = TRUE, cook.levels = c(0.5, 1.0),
add.smooth = getOption("add.smooth"), label.pos = c(4,2),
cex.caption = 1, cex.oma.main = 1.25)
**plot.lm**

Arguments

- **x**: `lm` object, typically result of `lm` or `glm`.
- **which**: if a subset of the plots is required, specify a subset of the numbers 1:6, see `caption` below (and the ‘Details’) for the different kinds.
- **caption**: captions to appear above the plots; `character` vector or `list` of valid graphics annotations, see `as.graphicsAnnot`, of length 6, the j-th entry corresponding to which[j]. Can be set to “” or NA to suppress all captions.
- **panel**: panel function. The useful alternative to `points`, `panel.smooth` can be chosen by `add.smooth = TRUE`.
- **sub.caption**: common title—above the figures if there are more than one; used as sub (s. `title`) otherwise. If NULL, as by default, a possible abbreviated version of `deparse(x$call)` is used.
- **main**: title to each plot—in addition to `caption`.
- **ask**: logical; if TRUE, the user is asked before each plot, see `par(ask=.)`.
- **...**: other parameters to be passed through to plotting functions.
- **id.n**: number of points to be labelled in each plot, starting with the most extreme.
- **labels.id**: vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.
- **cex.id**: magnification of point labels.
- **qqline**: logical indicating if a `qqline()` should be added to the normal Q-Q plot.
- **cook.levels**: levels of Cook’s distance at which to draw contours.
- **add.smooth**: logical indicating if a smoother should be added to most plots; see also `panel` above.
- **label.pos**: positioning of labels, for the left half and right half of the graph respectively, for plots 1-3.
- **cex.caption**: controls the size of `caption`.
- **cex oma.main**: controls the size of the `sub.caption` only if that is `above` the figures when there is more than one.

Details

`sub.caption`—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot, also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness (\(\sqrt{|E|}\)) is much less skewed than |E| for Gaussian zero-mean E).

The ‘S-L’, the Q-Q, and the Residual-Leverage plot, use standardized residuals which have identical variance (under the hypothesis). They are given as \(R_i/(s \times \sqrt{1 - h_{ii}})\) where \(h_{ii}\) are the diagonal entries of the hat matrix, `influence()`$\hat{\text{h}}$ (see also `hat`), and where the Residual-Leverage plot uses standardized Pearson residuals (`residuals.glm(type = "pearson")`) for \(R[i]\).

The Residual-Leverage plot shows contours of equal Cook’s distance, for values of `cook.levels` (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced `aov` situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook’s distance vs leverage/(1-leverage) plot, contours of standardized residuals (`rstandard(.)`) that are equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

```r
require(graphics)

## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi, data = LifeCycleSavings)
plot(lm.SR)

## 4 plots on 1 page;
## allow room for printing model formula in outer margin:
par(mfrow = c(2, 2), oma = c(0, 0, 2, 0))
plot(lm.SR)
plot(lm.SR, id.n = NULL) # no id's
plot(lm.SR, id.n = 5, labels.id = NULL) # 5 id numbers

## Was default in R <= 2.1.x:
## Cook's distances instead of Residual-Leverage plot
plot(lm.SR, which = 1:4)

## Fit a smooth curve, where applicable:
plot(lm.SR, panel = panel.smooth)
## Gives a smoother curve
plot(lm.SR, panel = function(x, y) panel.smooth(x, y, span = 1))

c <- c(2,1)
par(mfrow = c(2,1)) # same oma as above
plot(lm.SR, which = 1:2, sub.caption = "Saving Rates, n=50, p=5")
```
plot.ppr

Plot Ridge Functions for Projection Pursuit Regression Fit

Description

Plot the ridge functions for a projection pursuit regression (ppr) fit.

Usage

```r
## S3 method for class 'ppr'
plot(x, ask, type = "o", cex = 1/2,
     main = quote(bquote("term"[.(i)]*:~~\hat{beta}[.(i)] == .(bet.i))
                 ),
     xlab = quote(bquote(bold(alpha)[.(i)]^T * bold(x))),
     ylab = "", ...)```

Arguments

- `x` an R object of class "ppr" as produced by a call to ppr.
- `ask` the graphics parameter ask: see `par` for details. If set to TRUE will ask between the plot of each cross-section.
- `type` the type of line (see `plot.default`) to draw.
- `cex` plot symbol expansion factor (relative to `par("cex")`).
- `main`, `xlab`, `ylab` axis annotations, see also `title`. Can be an expression (depending on i and bet.i), as by default which will be `eval()`uated.
- `...` further graphical parameters, passed to `plot()`.

Value

None

Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

See Also

`ppr`, `par`

Examples

```r
require(graphics)
rock1 <- within(rock, { area1 <- area/10000; peri1 <- peri/10000 })
par(mfrow = c(3,2)) # maybe: , pty = "s")
rock.ppr <- ppr(log(perm) ~ area1 + peri1 + shape,
                data = rock1, nterms = 2, max.terms = 5)
plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)"
plot(update(rock.ppr, main = "update(..., bass = 5)"
plot(update(rock.ppr, main = "update(..., sm.method="gcv", gcvpen = 2),
              main = "update(..., sm.method="gcv", gcvpen=2)"
```
plot.profile.nls

Plot a profile.nls Object

Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with nls and profiled with profile.nls.

Usage

```r
## S3 method for class 'profile.nls'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100,
     absVal = TRUE, ylab = NULL, lty = 2, ...)
```

Arguments

- `x`: an object of class "profile.nls"
- `levels`: levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually `conf` is used instead of giving `levels` explicitly.
- `conf`: a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to `c(0.99, 0.95, 0.90, 0.80, 0.50)`.
- `absVal`: a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to `TRUE`.
- `lty`: the line type to be used for axis and dropped lines.
- `ylab`, `...`: other arguments to the `plot.default` function can be passed here (but not `xlab`, `xlim`, `ylim` nor `type`).

Details

The plots are produced in a set of hard-coded colours, but as these are coded by number their effect can be changed by setting the `palette`. Colour 1 is used for the axes and 4 for the profile itself. Colours 3 and 6 are used for the axis line at zero and the horizontal/vertical lines dropping to the axes.

par(opar)

plot.spec

Plotting Spectral Densities

Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

Usage

## S3 method for class 'spec'
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
   xlab = "frequency", ylab = NULL, type = "l",
   ci.col = "blue", ci.lty = 3,
   main = NULL, sub = NULL,
   plot.type = c("marginal", "coherency", "phase"),
   ...
)

plot.spec.phase(x, ci = 0.95,
   xlab = "frequency", ylab = "phase",
   ylim = c(-pi, pi), type = "l",
   main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
   xlab = "frequency",
   ylab = "squared coherency",
   ylim = c(0, 1), type = "l",
   main = NULL, ci.col = "blue", ci.lty = 3, ...)

Arguments

x     an object of class "spec".
add     logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".

Usage

ci coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.
log
If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal".

xlab
the x label of the plot.

ylab
the y label of the plot. If missing a suitable label will be constructed.

type
the type of plot to be drawn, defaults to lines.

ci.col
colour for plotting confidence bar or confidence intervals for coherency and phase.

ci.lty
line type for confidence intervals for coherency and phase.

main
overall title for the plot. If missing, a suitable title is constructed.

sub
a sub title for the plot. Only used for plot.type = "marginal". If missing, a description of the smoothing is used.

plot.type
For multivariate time series, the type of plot required. Only the first character is needed.

ylim, ...
Graphical parameters.

**plot.stepfun**

**Plot Step Functions**

**Description**
Method of the generic plot for stepfun objects and utility for plotting piecewise constant functions.

**Usage**

```r
## S3 method for class 'stepfun'
plot(x, xval, xlim, ylim = range(c(y, Fn.kn)),
     xlab = "x", ylab = "f(x)", main = NULL,
     add = FALSE, verticals = TRUE, do.points = (n < 1000),
     pch = par("pch"), col = par("col"),
     col.points = col, cex.points = par("cex"),
     col.hor = col, col.vert = col,
     lty = par("lty"), lwd = par("lwd"), ...)

## S3 method for class 'stepfun'
lines(x, ...)
```

**Arguments**

- **x**: an R object inheriting from “stepfun”.
- **xval**: numeric vector of abscissa values at which to evaluate `x`. Defaults to `knots(x)` restricted to `xlim`.
- **xlim, ylim**: limits for the plot region: see `plot.window`. Both have sensible defaults if omitted.
- **xlab, ylab**: labels for x and y axis.
- **main**: main title.
- **add**: logical; if TRUE only add to an existing plot.
- **verticals**: logical; if TRUE, draw vertical lines at steps.
- **do.points**: logical; if TRUE, also draw points at the (xlim restricted) knot locations. Default is true, for sample size < 1000.
- **pch**: character; point character if `do.points`.
- **col**: default color of all points and lines.
- **col.points**: character or integer code; color of points if `do.points`.
- **cex.points**: numeric; character expansion factor if `do.points`.
- **col.hor**: color of horizontal lines.
- **col.vert**: color of vertical lines.
- **lty, lwd**: line type and thickness for all lines.
- **...**: further arguments of `plot(.)`, or if(add) `segments(.)`.

**Value**

A list with two components

- **t**: abscissa (x) values, including the two outermost ones.
- **y**: y values ‘in between’ the t[].

**Author(s)**

**See Also**

- `ecdf` for empirical distribution functions as special step functions, `approxfun` and `splinefun`.

**Examples**

```r
require(graphics)
y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0, 3, by = 0.1)
op <- par(mfrow = c(2,2))
plot(sfun0); plot(sfun0, xval = tt, add = TRUE, col.hor = "bisque")
plot(sfun.2);plot(sfun.2, xval = tt, add = TRUE, col = "orange") # all colors
```
##-- This is revealing :
plot(sfun0, verticals = FALSE, main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = 1))[[i]], col = i)
legend(2.5, 1.9, paste("f =", c(0, 0.2, 1)), col = 1:3, lty = 1, y.intersp = 1)
par(op)

##-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df = 3), col.vert = "gray20")

---
plot.ts

### Plotting Time-Series Objects

Plotting method for objects inheriting from class "ts".

#### Usage

```r
## S3 method for class 'ts'
plot(x, y = NULL, plot.type = c("multiple", "single"), xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE, mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1), oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)
```

#### Arguments

- **x, y**: time series objects, usually inheriting from class "ts".
- **plot.type**: for multivariate time series, should the series be plotted separately (with a common time axis) or on a single plot? Can be abbreviated.
- **xy.labels**: logical, indicating if `text()` labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.
- **xy.lines**: logical, indicating if `lines` should be drawn for an x-y plot. Defaults to the value of `xy.labels` if that is logical, otherwise to TRUE.
- **panel**: a function(x, col, bg, pch, type, ...) which gives the action to be carried out in each panel of the display for `plot.type = "multiple"`. The default is `lines`.
- **nc**: the number of columns to use when `plot.type = "multiple"`. Defaults to 1 for up to 4 series, otherwise to 2.
- **yax.flip**: logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when `plot.type = "multiple"`. 

---

#### Description

Plotting method for objects inheriting from class "ts".
mar.multi, oma.multi
the (default) par settings for plot.type = "multiple". Modify with care!

axes
logical indicating if x- and y- axes should be drawn.

... additional graphical arguments, see plot, plot.default and par.

Details
If y is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on plot.type.

If y is present, both x and y must be univariate, and a scatter plot y ~ x will be drawn, enhanced by using text if xy.labels is TRUE or character, and lines if xy.lines is TRUE.

See Also
ts for basic time series construction and access functionality.

Examples
require(graphics)
## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
        start = c(1961, 1), frequency = 12)
plot(z, yax.flip = TRUE)
plot(z, axes = FALSE, ann = FALSE, frame.plot = TRUE,
     mar.multi = c(0,0,0,0), oma.multi = c(1,1,5,1))
title("plot(ts(..), axes=FALSE, ann=FALSE, frame.plot=TRUE, mar..., oma...)")

z <- window(z[,1:3], end = c(1969,12))
plot(z, type = "b")  # multiple

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")

## xy.lines and xy.labels are FALSE for large series:
plot(lag(sunspots, 1), sunspots, pch = ".")

SMI <- EuStockMarkets[, "SMI"]
plot(lag(SMI, 1), SMI, pch = ".")
plot(lag(SMI, 20), SMI, pch = ".", log = "xy",
     main = "4 weeks lagged SMI stocks -- log scale", xy.lines = TRUE)

---

Poisson

The Poisson Distribution

Description
Density, distribution function, quantile function and random generation for the Poisson distribution with parameter lambda.
Usage

dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)

Arguments

x vector of (non-negative integer) quantiles.
q vector of quantiles.
p vector of probabilities.
n number of random values to return.
lambda vector of (non-negative) means.
log, log.p logical; if TRUE, probabilities p are given as log(p).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The Poisson distribution has density

\[
p(x) = \frac{\lambda^x e^{-\lambda}}{x!}
\]

for \( x = 0, 1, 2, \ldots \). The mean and variance are \( E(X) = Var(X) = \lambda \).
Note that \( \lambda = 0 \) is really a limit case (setting \( 0^0 = 1 \)) resulting in a point mass at 0, see also the example.
If an element of \( x \) is not integer, the result of dpois is zero, with a warning. \( p(x) \) is computed using Loader’s algorithm, see the reference in dbinom.
The quantile is right continuous: qpois(p, lambda) is the smallest integer \( x \) such that \( P[X \leq x] \geq p \).
Setting lower.tail = FALSE allows to get much more precise results when the default, lower.tail = TRUE would return 1, see the example below.

Value

dpois gives the (log) density, ppois gives the (log) distribution function, qpois gives the quantile function, and rpois generates random deviates.
Invalid lambda will result in return value NaN, with a warning.
The length of the result is determined by \( n \) for rpois, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Source

dpois uses C code contributed by Catherine Loader (see dbinom).
ppois uses pgamma.
qpois uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.
rpois uses

```
poisson.test  

Exact Poisson tests

Description

Performs an exact test of a simple null hypothesis about the rate parameter in Poisson distribution, or for the ratio between two rate parameters.

Usage

```
poisson.test(x, T = 1, r = 1,
    alternative = c("two.sided", "less", "greater"),
    conf.level = 0.95)
```

Arguments

- `x` number of events. A vector of length one or two.
- `T` time base for event count. A vector of length one or two.
- `r` hypothesized rate or rate ratio
- `alternative` indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
- `conf.level` confidence level for the returned confidence interval.
Details

Confidence intervals are computed similarly to those of `binom.test` in the one-sample case, and using `binom.test` in the two sample case.

Value

A list with class "htest" containing the following components:

- **statistic**: the number of events (in the first sample if there are two.)
- **parameter**: the corresponding expected count
- **p.value**: the p-value of the test.
- **conf.int**: a confidence interval for the rate or rate ratio.
- **estimate**: the estimated rate or rate ratio.
- **null.value**: the rate or rate ratio under the null, \( r \).
- **alternative**: a character string describing the alternative hypothesis.
- **method**: the character string "Exact Poisson test" or "Comparison of Poisson rates" as appropriate.
- **data.name**: a character string giving the names of the data.

Note

The rate parameter in Poisson data is often given based on a “time on test” or similar quantity (person-years, population size, or expected number of cases from mortality tables). This is the role of the `T` argument.

The one-sample case is effectively the binomial test with a very large \( n \). The two sample case is converted to a binomial test by conditioning on the total event count, and the rate ratio is directly related to the odds in that binomial distribution.

### These are paraphrased from data sets in the ISwR package

#### SMR, Welsh Nickel workers

poisson.test(137, 24.19893)

#### eba1977, compare Fredericia to other three cities for ages 55-59

poisson.test(c(11, 6+8+7), c(800, 1083+1050+878))
Description

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points \( x \): these are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

Usage

\[
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE, simple = FALSE)
polym (..., degree = 1, coefs = NULL, raw = FALSE)
\]

## S3 method for class 'poly'
predict(object, newdata, ...)

Arguments

- \( x, \text{ newdata} \): a numeric vector at which to evaluate the polynomial. \( x \) can also be a matrix. Missing values are not allowed in \( x \).
- \( degree \): the degree of the polynomial. Must be less than the number of unique points when \( raw \) is false, as by default.
- \( coefs \): for prediction, coefficients from a previous fit.
- \( raw \): if true, use raw and not orthogonal polynomials.
- \( simple \): logical indicating if a simple matrix (with no further attributes but dimnames) should be returned. For speedup only.
- \( object \): an object inheriting from class "poly", normally the result of a call to \( \text{poly} \) with a single vector argument.
- \( ... \): \( \text{poly, polym} \): further vectors.
- \( \text{predict.poly} \): arguments to be passed to or from other methods.

Details

Although formally \( degree \) should be named (as it follows \( ... \)), an unnamed second argument of length 1 will be interpreted as the degree, such that \( \text{poly}(x, 3) \) can be used in formulas.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the predict part of the code.

\( \text{poly using } ... \) is just a convenience wrapper for \( \text{polym} \): \( \text{coefs} \) is ignored. Conversely, if \( \text{polym} \) is called with a single argument in \( ... \) it is a wrapper for \( \text{poly} \).

Value

For \( \text{poly and polym()} \) (when \( simple=FALSE \) and \( coefs=NULL \) as per default):

A matrix with rows corresponding to points in \( x \) and columns corresponding to the degree, with attributes "degree" specifying the degrees of the columns and (unless \( raw = \text{TRUE} \)) "coefs" which contains the centering and normalization constants used in constructing the orthogonal polynomials and class c("poly", "matrix").

For \( \text{poly(*, simple=TRUE)}, \text{polym(*, coefs=<non-NULL>)} \), and \( \text{predict.poly()} \): a matrix.
Note

This routine is intended for statistical purposes such as contr.poly: it does not attempt to orthogonalize to machine accuracy.

Author(s)

R Core Team. Keith Jewell (Campden BRI Group, UK) contributed improvements for correct prediction on subsets.

Examples

```r
od <- options(digits = 3) # avoid too much visual clutter
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
zapsmall(poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs")))

zm <- zapsmall(polym ( 1:4, c(1, 4:6), degree = 3)) # or just poly():
(z1 <- zapsmall(poly(cbind(1:4, c(1, 4:6)), degree = 3)))
## they are the same:
stopifnot(all.equal(zm, z1, tol = 1e-15))

## poly(<matrix>, df) --- used to fail till July 14 (vive la France!), 2017:
m2 <- cbind(1:4, c(1, 4:6))
pm2 <- zapsmall(poly(m2, 3)) # "unnamed degree = 3"
stopifnot(all.equal(pm2, zm, tol = 1e-15))

options(od)
```

---

**power**  
*Create a Power Link Object*

**Description**

Creates a link object based on the link function $\eta = \mu^\lambda$.

**Usage**

```
power(lambda = 1)
```

**Arguments**

- `lambda` a real number.
Details

If lambda is non-positive, it is taken as zero, and the log link is obtained. The default lambda = 1 gives the identity link.

Value

A list with components linkfun, linkinv, mu.eta, and valideta. See make.link for information on their meaning.

References

Examples

\[
\text{power()} \\
\text{quasi(link = power(1/3))[c("linkfun", "linkinv")]
}\]

Description

Compute power of test or determine parameters to obtain target power.

Usage

\[
\text{power.anova.test(groups = NULL, n = NULL,} \\
\quad \text{between.var = NULL, within.var = NULL,} \\
\quad \text{sig.level = 0.05, power = NULL)}
\]

Arguments

- **groups**: Number of groups
- **n**: Number of observations (per group)
- **between.var**: Between group variance
- **within.var**: Within group variance
- **sig.level**: Significance level (Type I error probability)
- **power**: Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters groups, n, between.var, power, within.var, and sig.level must be passed as NULL, and that parameter is determined from the others. Notice that sig.level has non-NULL default so NULL must be explicitly passed if you want it computed.
power.prop.test

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Claus Ekstrom

See Also

anova, lm, uniroot

Examples

power.anova.test(groups = 4, n = 5, between.var = 1, within.var = 3)
# Power = 0.3535594

power.anova.test(groups = 4, between.var = 1, within.var = 3,
                   power = .80)
# n = 11.92613

## Assume we have prior knowledge of the group means:
   groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
                 between.var = var(groupmeans),
                 within.var = 500, power = .90) # n = 15.18834

Description

Compute the power of the two-sample test for proportions, or determine parameters to obtain a target power.

Usage

power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,
                 power = NULL,
                 alternative = c("two.sided", "one.sided"),
                 strict = FALSE, tol = .Machine$double.eps^0.25)
power.prop.test

Arguments

- `n`: number of observations (per group)
- `p1`: probability in one group
- `p2`: probability in other group
- `sig.level`: significance level (Type I error probability)
- `power`: power of test (1 minus Type II error probability)
- `alternative`: one- or two-sided test. Can be abbreviated.
- `strict`: use strict interpretation in two-sided case
- `tol`: numerical tolerance used in root finding, the default providing (at least) four significant digits.

Details

Exactly one of the parameters `n`, `p1`, `p2`, `power`, and `sig.level` must be passed as NULL, and that parameter is determined from the others. Notice that `sig.level` has a non-NULL default so NULL must be explicitly passed if you want it computed.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Note that not all conditions can be satisfied, e.g., for

```r
power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8, strict=TRUE)
```

there is no proportion `p2` between `p1 = 0.9` and `1`, as you’d need a sample size of at least `n = 74` to yield the desired power for `(p1, p2) = (0.9, 1).

For these impossible conditions, currently a warning (`warning`) is signalled which may become an error (`stop`) in the future.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of `p1` and `p2` is computed, then `p1 < p2` is assumed and will hold, but if you specify both, `p2 ≤ p1` is allowed.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

power.prop.test(n = 50, p1 = .5, power = .90)  ## => p2 = 0.8026
power.prop.test(n = 50, p1 = .5, p2 = 0.9, power = .90, sig.level=NULL)  ## => sig.l = 0.00131
power.prop.test(p1 = .5, p2 = 0.501, sig.level=.001, power=0.90)  ## => n = 10451937
```

```r
try(
  power.prop.test(n=30, p1=0.90, p2=NULL, power=0.8)
)  # a warning (which may become an error)
## Reason:
power.prop.test(  p1=0.90, p2= 1.0, power=0.8)  ##-> n = 73.37
```

---

**power.t.test**  
*Power calculations for one and two sample t tests*

**Description**

Compute the power of the one- or two-sample t test, or determine parameters to obtain a target power.

**Usage**

```r
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05, 
            power = NULL, 
            type = c("two.sample", "one.sample", "paired"), 
            alternative = c("two.sided", "one.sided"), 
            strict = FALSE, tol = .Machine$double.eps^0.25)
```

**Arguments**

- `n` number of observations (per group)
- `delta` true difference in means
- `sd` standard deviation
- `sig.level` significance level (Type I error probability)
- `power` power of test (1 minus Type II error probability)
- `type` string specifying the type of t test. Can be abbreviated.
- `alternative` one- or two-sided test. Can be abbreviated.
- `strict` use strict interpretation in two-sided case
- `tol` numerical tolerance used in root finding, the default providing (at least) four significant digits.

**Details**

Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that the last two have non-NULL defaults, so `NULL` must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.
Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

uniroot is used to solve the power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

PP.test

Phillips-Perron Test for Unit Roots

Description

Computes the Phillips-Perron test for the null hypothesis that \( x \) has a unit root against a stationary alternative.

Usage

PP.test(x, lshort = TRUE)

Arguments

\( x \)

a numeric vector or univariate time series.

\( \text{lshort} \)

a logical indicating whether the short or long version of the truncation lag parameter is used.

Details

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate \( \sigma^2 \) the Newey-West estimator is used. If \( \text{lshort} \) is \( \text{TRUE} \), then the truncation lag parameter is set to \( \text{trunc}(4 \times \text{n/100})^{0.25} \), otherwise \( \text{trunc}(12 \times \text{n/100})^{0.25} \) is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee et al (1993).

Missing values are not handled.
Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic.
- parameter: the truncation lag parameter.
- p.value: the p-value of the test.
- method: a character string indicating what type of test was performed.
- data.name: a character string giving the name of the data.

x <- rnorm(1000)
PP.test(x)
y <- cumsum(x) # has unit root
PP.test(y)
```

ppoints

Ordinates for Probability Plotting

Description

Generates the sequence of probability points \((1:m - a)/(m + (1-a)\cdot a)\) where \(m\) is either \(n\), if \(\text{length}(n)==1\), or \(\text{length}(n)\).

Usage

```r
ppoints(n, a = if(n <= 10) 3/8 else 1/2)
```

Arguments

- `n`: either the number of points generated or a vector of observations.
- `a`: the offset fraction to be used; typically in \((0, 1)\).
Details

If $0 < a < 1$, the resulting values are within $(0, 1)$ (excluding boundaries). In any case, the resulting sequence is symmetric in $[0, 1]$, i.e., $p + \text{rev}(p) = 1$.

`ppoints()` is used in `qqplot` and `qqnorm` to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of $a$ follows the documentation of the function of the same name in Becker et al (1988), and appears to have been motivated by results from Blom (1958) on approximations to expect normal order statistics (see also `quantile`).

References

p.ppoints(10, a = 1/2)
p.ppoints(21)
p.ppoints(8) ; p.ppoints(8, a = 1/2, add=TRUE, col="tomato")
```
Description

Fit a projection pursuit regression model.

Usage

ppr(x, ...)

## S3 method for class 'formula'
ppr(formula, data, weights, subset, na.action,
    contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1, n),
    ww = rep(1, q), nterms, max.terms = nterms, optlevel = 2,
    sm.method = c("supsmu", "spline", "gcvspline"),
    bass = 0, span = 0, df = 5, gcvpen = 1, trace = FALSE, ...)

Arguments

formula  a formula specifying one or more numeric response variables and the explanatory variables.

x         numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.

y         numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.

nterms    number of terms to include in the final model.

data       a data frame (or similar: see model.frame) from which variables specified in formula are preferentially to be taken.

weights   a vector of weights w_i for each case.

ww        a vector of weights for each response, so the fit criterion is the sum over case i and responses j of w_i * ww_j * (y_ij - fit_ij)^2 divided by the sum of w_i.

subset    an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

na.action a function to specify the action to be taken if NAs are found. The default action is given by getOption("na.action"). (NOTE: If given, this argument must be named.)

contrasts the contrasts to be used when any factor explanatory variables are coded.

max.terms maximum number of terms to choose from when building the model.

optlevel   integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the ‘Details’ section.

sm.method  the method used for smoothing the ridge functions. The default is to use Friedman’s super smoother supsmu. The alternatives are to use the smoothing spline code underlying smooth.spline, either with a specified (equivalent) degrees of
freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.

Can be abbreviated.

bass super smoother bass tone control used with automatic span selection (see supsmu); the range of values is 0 to 10, with larger values resulting in increased smoothing.

span super smoother span control (see supsmu). The default, 0, results in automatic span selection by local cross validation. span can also take a value in (0, 1].

df if sm.method is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.

gcvpen if sm.method is "gcvspline" this is the penalty used in the GCV selection for each degree of freedom used.

trace logical indicating if each spline fit should produce diagnostic output (about lambda and df), and the supsmu fit about its steps.

... arguments to be passed to or from other methods.

model logical. If true, the model frame is returned.

Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS’s pprreg. This code is extremely sensitive to the compiler used.

The algorithm first adds up to max. terms ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until nterms terms are left.

The levels of optimization (argument optlevel) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are.

Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

Value

A list with the following components, many of which are for use by the method functions.

call the matched call
p the number of explanatory variables (after any coding)
q the number of response variables
mu the argument nterms
ml the argument max. terms
gof the overall residual (weighted) sum of squares for the selected model
gofn the overall residual (weighted) sum of squares against the number of terms, up to max. terms. Will be invalid (and zero) for less than nterms.
df the argument df
edf if sm.method is "spline" or "gcvspline" the equivalent number of degrees of freedom for each ridge term used.
xnames the names of the explanatory variables
ynames the names of the response variables
alpha a matrix of the projection directions, with a column for each ridge term
beta a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms
yb the weighted means of each response
ys the overall scale factor used: internally the responses are divided by ys to have unit total weighted sum of squares.
fitted.values the fitted values, as a matrix if q > 1.
residuals the residuals, as a matrix if q > 1.
smod internal work array, which includes the ridge functions evaluated at the training set points.
model (only if model = TRUE) the model frame.

Source

Friedman (1984): converted to double precision and added interface to smoothing splines by B. D. Ripley, originally for the MASS package.

prcomp

**Principal Components Analysis**

**Description**

Performs a principal components analysis on the given data matrix and returns the results as an object of class *prcomp*.

**Usage**

```r
prcomp(x, ...)  
```

## S3 method for class 'formula'

```r
prcomp(formula, data = NULL, subset, na.action, ...)
```

## Default S3 method:

```r
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,  
      tol = NULL, rank. = NULL, ...)
```

## S3 method for class 'prcomp'

```r
predict(object, newdata, ...)
```

**Arguments**

- **formula**: a formula with no response variable, referring only to numeric variables.
- **data**: an optional data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from `environment(formula)`.
- **subset**: an optional vector used to select rows (observations) of the data matrix `x`.
- **na.action**: a function which indicates what should happen when the data contain NAs. The default is set by the `na.action` setting of `options`, and is `na.fail` if that is unset. The ‘factory-fresh’ default is `na.omit`.
- **...**: arguments passed to or from other methods. If `x` is a formula one might specify `scale.` or `tol`.

---

par(mfrow = c(3,2))  # maybe: , pty = "s")
plot(rock.ppr, main = "ppr(log(perm)~ ., nterms=2, max.terms=5)"
plot(update(rock.ppr, bass = 5), main = "update(..., bass = 5)"
plot(update(rock.ppr, sm.method = "gcv", gcvpen = 2),
     main = "update(..., sm.method="gcv", gcvpen=2)")
cbind(perm = rock$perm, prediction = round(exp(predict(rock.ppr)), 1))
detach()
prcomp

x a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.

retx a logical value indicating whether the rotated variables should be returned.

center a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of x can be supplied. The value is passed to scale.

scale a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is FALSE for consistency with S, but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of x can be supplied. The value is passed to scale.

tol a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to tol times the standard deviation of the first component.) With the default null setting, no components are omitted (unless rank. is specified less than min(dim(x))). Other settings for tol could be tol = 0 or tol = sqrt(.Machine$double.eps), which would omit essentially constant components.

rank optionally, a number specifying the maximal rank, i.e., maximal number of principal components to be used. Can be set as alternative or in addition to tol, useful notably when the desired rank is considerably smaller than the dimensions of the matrix.

object object of class inheriting from "prcomp"

newdata An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, newdata must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using eigen on the covariance matrix. This is generally the preferred method for numerical accuracy. The print method for these objects prints the results in a nice format and the plot method produces a scree plot.

Unlike princomp, variances are computed with the usual divisor \( N - 1 \).

Note that scale = TRUE cannot be used if there are zero or constant (for center = TRUE) variables.

Value

prcomp returns a list with class "prcomp" containing the following components:

sdev the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).

rotation the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function princomp returns this in the element loadings.

x if retx is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the rotation matrix) is returned. Hence, cov(x) is the diagonal matrix diag(sdev^2). For the formula method, na.predict() is applied to handle the treatment of values omitted by the na.action.

center, scale the centering and scaling used, or FALSE.
Note
The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

predict

Model Predictions

Description
predict is a generic function for predictions from the results of various model fitting functions. The function invokes particular methods which depend on the class of the first argument.
predict (object, ...)  

Arguments  
object  a model object for which prediction is desired.  
...  additional arguments affecting the predictions produced.  

Details  
Most prediction methods which are similar to those for linear models have an argument newdata specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in newdata to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).  
 Time series prediction methods in package stats have an argument n.ahead specifying how many time steps ahead to predict.  
Many methods have a logical argument se.fit saying if standard errors are to returned.  

Value  
The form of the value returned by predict depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.  

References

  }, silent = TRUE)  
## IGNORE_RDIFF_END
predict.Arima

**Forecast from ARIMA fits**

**Description**
Forecast from models fitted by `arima`.

**Usage**

```r
## S3 method for class 'Arima'
predict(object, n.ahead = 1, newxreg = NULL,
        se.fit = TRUE, ...)
```

**Arguments**

- `object`: The result of an `arima` fit.
- `n.ahead`: The number of steps ahead for which prediction is required.
- `newxreg`: New values of `xreg` to be used for prediction. Must have at least `n.ahead` rows.
- `se.fit`: Logical: should standard errors of prediction be returned?
- `...`: arguments passed to or from other methods.

**Details**
Finite-history prediction is used, via `KalmanForecast`. This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

**Value**
A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

`arima`
Examples

od <- options(digits = 5) # avoid too much spurious accuracy
predict(arima(lh, order = c(3,0,0)), n.ahead = 12)

(fit <- arima(USAccDeaths, order = c(0,1,1),
seasonal = list(order = c(0,1,1))))
predict(fit, n.ahead = 6)
options(od)

predict.glm

Predict Method for GLM Fits

Description

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

Usage

## S3 method for class 'glm'
predict(object, newdata = NULL,
type = c("link", "response", "terms"),
se.fit = FALSE, dispersion = NULL, terms = NULL,
na.action = na.pass, ...)

Arguments

object a fitted object of class inheriting from "glm".
newdata optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
type the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale. The value of this argument can be abbreviated.
se.fit logical switch indicating if standard errors are required.
dispersion the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by summary applied to the object is used.
terms with type = "terms" by default all terms are returned. A character vector specifies which terms are to be returned
na.action function determining what should be done with missing values in newdata. The default is to predict NA.
... further arguments passed to or from other methods.
Details

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value NA. See also `napredict`.

Value

If `se.fit = FALSE`, a vector or matrix of predictions. For `type = "terms"` this is a matrix with a column per term, and may have an attribute "constant".

If `se.fit = TRUE`, a list with components

- `fit` Predictions, as for `se.fit = FALSE`.
- `se.fit` Estimated standard errors.
- `residual.scale` A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

```
predict.HoltWinters  Prediction Function for Fitted Holt-Winters Models

Description
Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

Usage

## S3 method for class 'HoltWinters'
predict(object, n.ahead = 1, prediction.interval = FALSE,
          level = 0.95, ...)

Arguments

object  An object of class HoltWinters.
n.ahead Number of future periods to predict.
prediction.interval
          logical. If TRUE, the lower and upper bounds of the corresponding prediction
          intervals are computed.
level  Confidence level for the prediction interval.
...  arguments passed to or from other methods.

Value
A time series of the predicted values. If prediction intervals are requested, a multiple time series is
returned with columns fit, lwr and upr for the predicted values and the lower and upper bounds
respectively.

p <- predict(m, 50, prediction.interval = TRUE)
plot(m, p)
predict.lm

**Predict method for Linear Model Fits**

**Description**

Predicted values based on linear model object.

**Usage**

```r
## S3 method for class 'lm'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, type = c("response", "terms"),
        terms = NULL, na.action = na.pass,
        pred.var = res.var/weights, weights = 1, ...)
```

**Arguments**

- **object**: Object of class inheriting from "lm"
- **newdata**: An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
- **se.fit**: A switch indicating if standard errors are required.
- **scale**: Scale parameter for std.err. calculation.
- **df**: Degrees of freedom for scale.
- **interval**: Type of interval calculation. Can be abbreviated.
- **level**: Tolerance/confidence level.
- **type**: Type of prediction (response or model term). Can be abbreviated.
- **terms**: If `type = "terms"`, which terms (default is all terms), a character vector.
- **na.action**: function determining what should be done with missing values in `newdata`. The default is to predict NA.
- **pred.var**: the variance(s) for future observations to be assumed for prediction intervals. See ‘Details’.
- **weights**: variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in `newdata`.
- **...**: further arguments passed to or from other methods.

**Details**

`predict.lm` produces predicted values, obtained by evaluating the regression function in the frame `newdata` (which defaults to `model.frame(object)`). If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified `level`, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if `newdata` is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.
If newdata is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit are handled is determined by the na.action argument of that fit. If na.action = na.omit omitted cases will not appear in the predictions, whereas if na.action = na.exclude they will appear (in predictions, standard errors or interval limits), with value NA. See also napredict.

The prediction intervals are for a single observation at each case in newdata (or by default, the data used for the fit) with error variance(s) pred.var. This can be a multiple of res.var, the estimated value of \( \sigma^2 \): the default is to assume that future observations have the same error variance as those used for fitting. If weights is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, weights defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and newdata is given, the default is to assume constant prediction variance, with a warning.

**Value**

predict.lm produces a vector of predictions or a matrix of predictions and bounds with column names fit, lwr, and upr if interval is set. For type = "terms" this is a matrix with a column per term and may have an attribute "constant".

If se.fit is TRUE, a list with the following components is returned:

- fit: vector or matrix as above
- se.fit: standard error of predicted means
- residual.scale: residual standard deviations
- df: degrees of freedom for residual

**Note**

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

Notice that prediction variances and prediction intervals always refer to future observations, possibly corresponding to the same predictors as used for the fit. The variance of the residuals will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if res.var is not obtained from the fit.

**See Also**

The model fitting function lm, predict.

SafePrediction for prediction from (univariable) polynomial and spline fits.

**Examples**

```r
require(graphics)

## Predictions
x <- rnorm(15)
y <- x + rnorm(15)
predict(lm(y ~ x))
new <- data.frame(x = seq(-3, 3, 0.5))
predict(lm(y ~ x), new, se.fit = TRUE)
```

## S3 method for class 'loess'
predict(object, newdata = NULL, se = FALSE, na.action = na.pass, ...)

### Arguments

- **object**: an object fitted by loess.
- **newdata**: an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needs for prediction. If missing, the original data points are used.
- **se**: should standard errors be computed?
- **na.action**: function determining what should be done with missing values in data frame newdata. The default is to predict NA.
- **...**: arguments passed to or from other methods.

### Details

The standard errors calculation is slower than prediction.
When the fit was made using surface = “interpolate” (the default), predict.loess will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.
predict.nls

Predicting from Nonlinear Least Squares Fits

Description

predict.nls produces predicted values, obtained by evaluating the regression function in the frame newdata. If the logical se.fit is TRUE, standard errors of the predictions are calculated. If the numeric argument scale is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting intervals specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present se.fit and interval are ignored.
predict.nls

Usage

## S3 method for class 'nls'
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, ...)

Arguments

object An object that inherits from class nls.
newdata A named list or data frame in which to look for variables with which to predict.
If newdata is missing the fitted values at the original data points are returned.
se.fit A logical value indicating if the standard errors of the predictions should be calculated. Defaults to FALSE. At present this argument is ignored.
scale A numeric scalar. If it is set (with optional df), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.
df A positive numeric scalar giving the number of degrees of freedom for the scale estimate. At present this argument is ignored.
interval A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.
level A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.
... Additional optional arguments. At present no optional arguments are used.

Value

predict.nls produces a vector of predictions. When implemented, interval will produce a matrix of predictions and bounds with column names fit, lwr, and upr. When implemented, if se.fit is TRUE, a list with the following components will be returned:

fit vector or matrix as above
se.fit standard error of predictions
residual.scale residual standard deviations
df degrees of freedom for residual

Note

Variables are first looked for in newdata and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in newdata if it was supplied.

par(opar)
```

**predict.smooth.spline**  
*Predict from Smoothing Spline Fit*

Description

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

Usage

```r
## S3 method for class 'smooth.spline'
predict(object, x, deriv = 0, ...)
```

Arguments

- `object`  
a fit from `smooth.spline`.
- `x`  
the new values of x.
- `deriv`  
integer; the order of the derivative required.
- `...`  
further arguments passed to or from other methods.

Value

A list with components

- `x`  
The input x.
- `y`  
The fitted values or derivatives at x.

See Also

`smooth.spline`
Examples

```r

cars.spl <- smooth.spline(speed, dist, df = 6.4)

## "Proof" that the derivatives are okay, by comparing with approximation
diff.quot <- function(x, y) {
  ## Difference quotient (central differences where available)
  n <- length(x); i1 <- 1:2; i2 <- (n-1):n
  c(diff(y[i1]) / diff(x[i1]), (y[-i1] - y[-i2]) / (x[-i1] - x[-i2]),
     diff(y[i2]) / diff(x[i2]))
}

xx <- unique(sort(c(seq(0, 30, by = .2), kn <- unique(speed))))
i.kn <- match(kn, xx) # indices of knots within xx
op <- par(mfrow = c(2,2))
plot(speed, dist, xlim = range(xx), main = "Smooth.spline & derivatives")
lines(pp <- predict(cars.spl, xx), col = "red")
points(kn, pp$y[i.kn], pch = 3, col = "dark red")
mtext("s(x)", col = "red")
for(d in 1:3){
  n <- length(pp$x)
  plot(pp$x, diff.quot(pp$x,pp$y), type = "l", xlab = "x", ylab = "",
       col = "blue", col.main = "red",
       main = paste0("s", paste(rep("/"Var", d), collapse = ", "), "(x)"))
  mtext("Difference quotient approx.(last)", col = "blue")
  lines(pp <- predict(cars.spl, xx, deriv = d), col = "red")
  points(kn, pp$y[i.kn], pch = 3, col = "dark red")
  abline(h = 0, lty = 3, col = "gray")
}
detach(); par(op)
```

preplot

---

**Pre-computations for a Plotting Object**

Description

Compute an object to be used for plots relating to the given model object.

Usage

```r
preplot(object, ...)
```

Arguments

- `object` a fitted model object.
- `...` additional arguments for specific methods.
princomp

Details

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

Value

An object set up to make a plot that describes object.

princomp  Principal Components Analysis

Description

princomp performs a principal components analysis on the given numeric data matrix and returns the results as an object of class princomp.

Usage

princomp(x, ...)

## S3 method for class 'formula'
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
    subset = rep_len(TRUE, nrow(as.matrix(x))), fix_sign = TRUE, ...)

## S3 method for class 'princomp'
predict(object, newdata, ...)

Arguments

formula  a formula with no response variable, referring only to numeric variables.
data  an optional data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset  an optional vector used to select rows (observations) of the data matrix x.
na.action  a function which indicates what should happen when the data contain NAs. The default is set by the na.action setting of options, and is na.fail if that is unset. The ‘factory-fresh’ default is na.omit.
x  a numeric matrix or data frame which provides the data for the principal components analysis.
cor  a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
scores  a logical value indicating whether the score on each principal component should be calculated.
princomp

covmat  a covariance matrix, or a covariance list as returned by `cov.wt` (and `cov.mve` or `cov.mcd` from package `MASS`). If supplied, this is used rather than the covariance matrix of \( x \).

fix_sign  Should the signs of the loadings and scores be chosen so that the first element of each loading is non-negative?

...  arguments passed to or from other methods. If \( x \) is a formula one might specify `cor` or `scores`.

object  Object of class inheriting from "princomp".

newdata  An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, `newdata` must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

princomp is a generic function with "formula" and "default" methods.

The calculation is done using `eigen` on the correlation or covariance matrix, as determined by `cor`. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use `svd` on \( x \), as is done in `prcomp`.

Note that the default calculation uses divisor \( N \) for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (`screeplot`). There is also a `biplot` method.

If \( x \) is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

princomp only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

Value

princomp returns a list with class "princomp" containing the following components:

- `sdev`  the standard deviations of the principal components.
- `loadings`  the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see `loadings` for its print method.
- `center`  the means that were subtracted.
- `scale`  the scalings applied to each variable.
- `n.obs`  the number of observations.
- `scores`  if `scores = TRUE`, the scores of the supplied data on the principal components. These are non-null only if \( x \) was supplied, and if `covmat` was also supplied if it was a covariance list. For the formula method, `napredict()` is applied to handle the treatment of values omitted by the `na.action`.
- `call`  the matched call.
- `na.action`  If relevant.
Note
The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R. fix_sign = TRUE alleviates that.

print.power.htest  Print Methods for Hypothesis Tests and Power Calculation Objects

Description
Printing objects of class "htest" or "power.htest", respectively, by simple print methods.
Usage

```r
## S3 method for class 'htest'
print(x, digits = getOption("digits"), prefix = "\t", ...)

## S3 method for class 'power.htest'
print(x, digits = getOption("digits"), ...)
```

Arguments

- `x`: object of class "htest" or "power.htest".
- `digits`: number of significant digits to be used.
- `prefix`: string, passed to `strwrap` for displaying the method component of the `htest` object.
- `...`: further arguments to be passed to or from methods.

Details

Both `print` methods traditionally have not obeyed the `digits` argument properly. They now do, the `htest` method mostly in expressions like `max(1, digits - 2)`.

A `power.htest` object is just a named list of numbers and character strings, supplemented with `method` and `note` elements. The `method` is displayed as a title, the `note` as a footnote, and the remaining elements are given in an aligned `name = value` format.

Value

the argument `x`, invisibly, as for all `print` methods.

Author(s)

Peter Dalgaard

See Also

`power.t.test`, `power.prop.test`

Examples

```r
(ptt <- power.t.test(n = 20, delta = 1))
print(ptt, digits = 4) # using less digits than default
print(ptt, digits = 12) # using more "      "
```

Description

Notably for calendar related time series objects, `format` and `print` methods showing years, months and or quarters respectively.
## S3 method for class 'ts'
print(x, calendar, ...)

Arguments

- **x**: a time series object.
- **calendar**: enable/disable the display of information about month names, quarter names or year when printing. The default is `TRUE` for a frequency of 4 or 12, `FALSE` otherwise.
- **...**: additional arguments to `print` (or `format` methods).

Details

The `print` method for "ts" objects prints a header (basically of `tsp(x)`), if calendar is false, and then prints the result of `.preformat.ts(x, *)`, which is typically a matrix with rownames built from the calendar times where applicable.

See Also

`print`, `ts`.

Examples

```r
print(ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)

print(sunsp.1 <- window(sunspot.month, end=c(1756, 12)))
m <- .preformat.ts(sunsp.1) # a character matrix
```

---

### Description

Utility function to be used in higher-level `print` methods, such as those for `summary.lm`, `summary.glm` and `anova`. The goal is to provide a flexible interface with smart defaults such that often, only `x` needs to be specified.

Usage

```r
printCoefmat(x, digits = max(3, getOption("digits") - 2),
  signif.stars = getOption("show.signif.stars"),
  signif.legend = signif.stars,
  dig.tst = max(1, min(5, digits - 1)),
  cs.ind = 1L:k, tst.ind = k + 1L,
  zap.ind = integer(), P.values = NULL,
  has.Pvalue = nc >= 4L && length(cn <- colnames(x)) &&
    substr(cn[nc], 1L, 3L) %in% c("Pr", "p-v"),
  eps.Pvalue = .Machine$double.eps,
  na.print = "NA", ...)
```
Arguments

x  a numeric matrix like object, to be printed.
digits  minimum number of significant digits to be used for most numbers.
signif.stars  logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the show.signif.stars slot of options.
signif.legend  logical; if TRUE, a legend for the ‘significance stars’ is printed provided signif.stars = TRUE.
dig.tst  minimum number of significant digits for the test statistics, see tst.ind.
cs.ind  indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.
tst.ind  indices (integer) of column numbers for test statistics.
zap.ind  indices (integer) of column numbers which should be formatted by zapsmall, i.e., by ‘zapping’ values close to 0.
P.values  logical or NULL; if TRUE, the last column of x is formatted by format.pval as P values. If P.values = NULL, the default, it is set to TRUE only if options("show.coef.Pvalue") is TRUE and x has at least 4 columns and the last column name of x starts with "Pr(".
has.Pvalue  logical; if TRUE, the last column of x contains P values; in that case, it is printed if and only if P.values (above) is true.
eps.Pvalue  number, ...
na.print  a character string to code NA values in printed output.
...  further arguments for print.

Value

Invisibly returns its argument, x.

cmat <- cbind(cmat, 2*pnorm(-cmat[, 3]))
colnames(cmat) <- c("Estimate", "Std.Err", "Z value", "Pr(>z)")
printCoefmat(cmat[, 1:3])
printCoefmat(cmat)
op <- options(show.coef.Pvalues = FALSE)
printCoefmat(cmat, digits = 2)
printCoefmat(cmat, digits = 2, P.values = TRUE)
options(op) # restore
**profile**

**Generic Function for Profiling Models**

**Description**
Investigates behavior of objective function near the solution represented by fitted. See documentation on method functions for further details.

**Usage**

`profile(fitted, ...)`

**Arguments**

- `fitted`: the original fitted model object.
- `...`: additional parameters. See documentation on individual methods.

**Value**

A list with an element for each parameter being profiled. See the individual methods for further details.

**See Also**

`profile.nls`, `profile.glm` in package `MASS`, ...
For profiling R code, see `Rprof`.

---

**profile.nls**

**Method for Profiling nls Objects**

**Description**

Investigates the profile log-likelihood function for a fitted model of class "nls".

**Usage**

```r
## S3 method for class 'nls'
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
        delta.t = cutoff/5, ...)
```

**Arguments**

- `fitted`: the original fitted model object.
- `which`: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.
- `maxpts`: maximum number of points to be used for profiling each parameter.
- `alphamax`: highest significance level allowed for the profile t-statistics.
- `delta.t`: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `...`: further arguments passed to or from other methods.
Details

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list with an element for each parameter being profiled. The elements are data-frames with two variables

par.vals a matrix of parameter values for each fitted model.
tau the profile t-statistics.

proj

Projections of Models

Description

proj returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for aov models.
Usage

proj(object, ...)

## S3 method for class 'aov'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## S3 method for class 'aovlist'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm'
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

Arguments

object     An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components qr and effects.
onedf      A logical flag. If TRUE, a projection is returned for all the columns of the model matrix. If FALSE, the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table).
unweighted.scale If the fit producing object used weights, this determines if the projections correspond to weighted or unweighted observations.
...        Swallow and ignore any other arguments.

Details

A projection is given for each stratum of the object, so for aov models with an Error term the result is a list of projections.

Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (onedf = FALSE) or for each coefficient (onedf = TRUE). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the Q matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for lm and aov models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when onedf = FALSE the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

Author(s)

The design was inspired by the S function of the same name described in Chambers et al (1992).

```

---

**prop.test**  
*Test of Equal or Given Proportions*

**Description**

*prop.test* can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

**Usage**

```r
prop.test(x, n, p = NULL, 
  alternative = c("two.sided", "less", "greater"),
  conf.level = 0.95, correct = TRUE)
```

**Arguments**

- `x` a vector of counts of successes, a one-dimensional table with two entries, or a two-dimensional table (or matrix) with 2 columns, giving the counts of successes and failures, respectively.
- `n` a vector of counts of trials; ignored if `x` is a matrix or a table.
- `p` a vector of probabilities of success. The length of `p` must be the same as the number of groups specified by `x`, and its elements must be greater than 0 and less than 1.
alternative  a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

conf.level  confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.

correct  a logical indicating whether Yates' continuity correction should be applied where possible.

Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If p is NULL and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by alternative. A confidence interval for the difference of proportions with confidence level as specified by conf.level and clipped to \([-1,1]\) is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is p, or .5 if p is not given. The alternative is that the probability of success is less than, not equal to, or greater than p or 0.5, respectively, as specified by alternative. A confidence interval for the underlying proportion with confidence level as specified by conf.level and clipped to [0,1] is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if p is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by p. The alternative is always "two.sided", the returned confidence interval is NULL, and continuity correction is never used.

Value

A list with class "htest" containing the following components:

- statistic  the value of Pearson's chi-squared test statistic.
- parameter  the degrees of freedom of the approximate chi-squared distribution of the test statistic.
- p.value  the p-value of the test.
- estimate  a vector with the sample proportions x/n.
- conf.int  a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and p is not given, or NULL otherwise. In the cases where it is not NULL, the returned confidence interval has an asymptotic confidence level as specified by conf.level, and is appropriate to the specified alternative hypothesis.
- null.value  the value of p if specified by the null, or NULL otherwise.
- alternative  a character string describing the alternative.
prop.trend.test

Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

Usage

prop.trend.test(x, n, score = seq_along(x))

Arguments

x Number of events
n Number of trials
score Group score

method a character string indicating the method used, and whether Yates’ continuity correction was applied.
data.name a character string giving the names of the data.

References

prop.trend.test(smokers, patients)
prop.trend.test(smokers, patients, c(0,0,0,1))
```

---

**qqnorm**

**Quantile-Quantile Plots**

Description

qqnorm is a generic function the default method of which produces a normal QQ plot of the values in `y`. `qqline` adds a line to a “theoretical”, by default normal, quantile-quantile plot which passes through the probs quantiles, by default the first and third quartiles.

`qqplot` produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to `qqnorm`, `qqplot` and `qqline`.

Usage

```r
qqnorm(y, ...)

## Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, distribution = qnorm,
probs = c(0.25, 0.75), qtype = 7, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),
ylab = deparse(substitute(y)), ...)
```
**Arguments**

- `x`: The first sample for `qqplot`.
- `y`: The second or only data sample.
- `xlab, ylab, main`: plot labels. The `xlab` and `ylab` refer to the y and x axes respectively if `datax = TRUE`.
- `plot.it`: logical. Should the result be plotted?
- `datax`: logical. Should data values be on the x-axis?
- `distribution`: quantile function for reference theoretical distribution.
- `probs`: numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
- `qtype`: the type of quantile computation used in `quantile`.
- `ylim, ...`: graphical parameters.

**Value**

For `qqnorm` and `qqplot`, a list with components

- `x`: The x coordinates of the points that were/would be plotted
- `y`: The original y vector, i.e., the corresponding y coordinates including NAs.

**References**

**See Also**

`ppoints`, used by `qqnorm` to generate approximations to expected order statistics for a normal distribution.

**Examples**

```r
require(graphics)
y <- rt(200, df = 5)
qqnorm(y); qqline(y, col = 2)
qqplot(y, rt(300, df = 5))
qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")
```

```r
## "QQ-Chisquare" : -----------------------------
y <- rchisq(500, df = 3)
## Q-Q plot for Chi^2 data against true theoretical distribution:
qqplot(qchisq(ppoints(500), df = 3), y,
      main = expression("Q-Q plot for" ~ {chi^2}[nu == 3]))
qqline(y, distribution = function(p) qchisq(p, df = 3),
       prob = c(0.1, 0.6), col = 2)
mtext("qqline(*, dist = qchisq(. , df=3), prob = c(0.1, 0.6))")
```
quade.test

Quade Test

Description

Performs a Quade test with unreplicated blocked data.

Usage

quade.test(y, ...)

## Default S3 method:
quade.test(y, groups, blocks, ...)

## S3 method for class 'formula'
quade.test(formula, data, subset, na.action, ...)

Arguments

y
  either a numeric vector of data values, or a data matrix.
groups
  a vector giving the group for the corresponding elements of y if this is a vector;
  ignored if y is a matrix. If not a factor object, it is coerced to one.
blocks
  a vector giving the block for the corresponding elements of y if this is a vector;
  ignored if y is a matrix. If not a factor object, it is coerced to one.
formula
  a formula of the form a ~ b | c, where a, b and c give the data values and
  corresponding groups and blocks, respectively.
data
  an optional matrix or data frame (or similar: see model.frame) containing
  the variables in the formula formula. By default the variables are taken from
  environment(formula).
subset
  an optional vector specifying a subset of observations to be used.
na.action
  a function which indicates what should happen when the data contain NAs. De-
 faults togetOption("na.action").
...  further arguments to be passed to or from methods.

Details

quade.test can be used for analyzing unreplicated complete block designs (i.e., there is exactly
one observation in y for each combination of levels of groups and blocks) where the normality
assumption may be violated.

The null hypothesis is that apart from an effect of blocks, the location parameter of y is the same
in each of the groups.

If y is a matrix, groups and blocks are obtained from the column and row indices, respectively.
NA’s are not allowed in groups or blocks; if y contains NA’s, corresponding blocks are removed.
quantile

Value

A list with class "htest" containing the following components:

statistic  the value of Quade’s F statistic.
parameter  a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
p.value   the p-value of the test.
method    the character string "Quade test".
data.name  a character string giving the names of the data.

quade.test(y)

quantile

Sample Quantiles

Description

The generic function quantile produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.
Usage

quantile(x, ...)

## Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE, 
    names = TRUE, type = 7, ...)

Arguments

x numeric vector whose sample quantiles are wanted, or an object of a class for 
which a method has been defined (see also ‘details’). NA and NaN values are not 
allowed in numeric vectors unless na.rm is TRUE.

probs numeric vector of probabilities with values in [0, 1]. (Values up to ‘2e-14’ out-
side that range are accepted and moved to the nearby endpoint.)

na.rm logical; if true, any NA and NaN’s are removed from x before the quantiles are 
computed.

names logical; if true, the result has a names attribute. Set to FALSE for speedup with 
many probs.

type an integer between 1 and 9 selecting one of the nine quantile algorithms detailed 
below to be used.

... further arguments passed to or from other methods.

Details

A vector of length length(probs) is returned; if names = TRUE, it has a names attribute.

NA and NaN values in probs are propagated to the result.

The default method works with classed objects sufficiently like numeric vectors that sort and (not 
needed by types 1 and 3) addition of elements and multiplication by a number work correctly. Note 
that as this is in a namespace, the copy of sort in base will be used, not some S4 generic of that 
name. Also note that that is no check on the ‘correctly’, and so e.g. quantile can be applied to 
complex vectors which (apart from ties) will be ordered on their real parts.

There is a method for the date-time classes (see "POSIXt"). Types 1 and 3 can be used for class 
"Date" and for ordered factors.

Types

quantile returns estimates of underlying distribution quantiles based on one or two order statistics 
from the supplied elements in x at probabilities in probs. One of the nine quantile algorithms 
discussed in Hyndman and Fan (1996), selected by type, is employed.

All sample quantiles are defined as weighted averages of consecutive order statistics. Sample quan-
tiles of type \( i \) are defined by:

\[
Q_i(p) = (1 - \gamma) x_j + \gamma x_{j+1}
\]

where \( 1 \leq i \leq 9 \), \( \frac{i - m}{n} \leq p < \frac{i - m + 1}{n} \), \( x_j \) is the \( j \)th order statistic, \( n \) is the sample size, the value 
of \( \gamma \) is a function of \( j = \lceil np + m \rceil \) and \( g = np + m - j \), and \( m \) is a constant determined by the 
example quantile type.

Discontinuous sample quantile types 1, 2, and 3

For types 1, 2 and 3, \( Q_i(p) \) is a discontinuous function of \( p \), with \( m = 0 \) when \( i = 1 \) and \( i = 2 \), and 
\( m = -1/2 \) when \( i = 3 \).
Type 1 Inverse of empirical distribution function. $\gamma = 0$ if $g = 0$, and 1 otherwise.
Type 2 Similar to type 1 but with averaging at discontinuities. $\gamma = 0.5$ if $g = 0$, and 1 otherwise.
Type 3 SAS definition: nearest even order statistic. $\gamma = 0$ if $g = 0$ and $j$ is even, and 1 otherwise.

Continuous sample quantile types 4 through 9
For types 4 through 9, $Q_i(p)$ is a continuous function of $p$ with $\gamma = g$ and $m$ given below. The sample quantiles can be obtained equivalently by linear interpolation between the points $(p_k, x_k)$ where $x_k$ is the $k$th order statistic. Specific expressions for $p_k$ are given below.

Type 4 $m = 0$. $p_k = k/n$. That is, linear interpolation of the empirical cdf.
Type 5 $m = 1/2$. $p_k = k - 0.5/n$. That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.
Type 6 $m = p$. $p_k = k/n$. Thus $p_k = E[F(x_k)]$. This is used by Minitab and by SPSS.
Type 7 $m = 1 - p$. $p_k = k/n - 1$. In this case, $p_k = \text{mode}[F(x_k)]$. This is used by S.
Type 8 $m = (p + 1)/3$. $p_k = k - 1/3/n + 1/3$. Then $p_k \approx \text{median}[F(x_k)]$. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of $x$.
Type 9 $m = p/4 + 3/8$. $p_k = k - 3/8/n + 1/4$. The resulting quantile estimates are approximately unbiased for the expected order statistics if $x$ is normally distributed.

Further details are provided in Hyndman and Fan (1996) who recommended type 8. The default method is type 7, as used by S and by R < 2.0.0.

Author(s)
of the version used in R >= 2.0.0, Ivan Frohne and Rob J Hyndman.

### Compare different types
quantAll <- function(x, prob, ...)
 t(vapply(1:9, function(typ) quantile(x, prob=prob, type = typ, ...), quantile(x, prob, type=1)))
p <- c(0.1, 0.5, 1, 2, 5, 10, 50)/100
signif(quantAll(x, p), 4)

### for complex numbers:
z <- complex(re=x, im = -10*x)
signif(quantAll(z, p), 4)
**r2dtable**  
*Random 2-way Tables with Given Marginals*

**Description**

Generate random 2-way tables with given marginals using Patefield’s algorithm.

**Usage**

```r
r2dtable(n, r, c)
```

**Arguments**

- `n`: a non-negative numeric giving the number of tables to be drawn.
- `r`: a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as `c`.
- `c`: a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

**Value**

A list of length `n` containing the generated tables as its components.

**References**

**Examples**

```r
## Fisher's Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
nrow = 2,
dimnames = list(Guess = c("Milk", "Tea"),
               Truth = c("Milk", "Tea")))
## Simulate permutation test for independence based on the maximum Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)
expected <- outer(rowTotals, colTotals, "*") / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...
```
Manipulate Flat Contingency Tables

Description

Read, write and coerce 'flat' contingency tables.

Usage

read.ftable(file, sep = "", quote = "\"",
             row.var.names, col.vars, skip = 0)

write.ftable(x, file = "", quote = TRUE, append = FALSE,
             digits = getOption("digits"), ...)

## S3 method for class 'ftable'
format(x, quote = TRUE, digits = getOption("digits"),
       method = c("non.compact", "row.compact",
                  "col.compact", "compact"),
       lsep = " | ", ...)

## S3 method for class 'ftable'
print(x, digits = getOption("digits"), ...)

Arguments

file

either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.

sep

the field separator string. Values on each line of the file are separated by this string.

quote

a character string giving the set of quoting characters for read.ftable; to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.

row.var.names

a character vector with the names of the row variables, in case these cannot be determined automatically.

col.vars

a list giving the names and levels of the column variables, in case these cannot be determined automatically.

skip

the number of lines of the data file to skip before beginning to read data.

x

an object of class "ftable".

append

logical. If TRUE and file is the name of a file (and not a connection or "|cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.

digits

an integer giving the number of significant digits to use for (the cell entries of) x.

method

string specifying how the "ftable" object is formatted (and printed if used as in write.ftable() or the print method). Can be abbreviated. Available methods are (see the examples):

"non.compact" the default representation of an "ftable" object.
"row.compact" a row-compact version without empty cells below the column labels.
"col.compact" a column-compact version without empty cells to the right of the row labels.
"compact" a row- and column-compact version. This may imply a row and a column label sharing the same cell. They are then separated by the string lsep.

lsep only for method = "compact", the separation string for row and column labels.

... further arguments to be passed to or from methods; for write() and print(), notably arguments such as method, passed to format().

Details
read.ftable reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using skip, and providing the names of the row variables and the names and levels of the column variable using row.var.names and col.vars, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use read.table to read in the data, and create the contingency table from this using xtabs.

write.ftable writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables. Different versions are available via the method argument, which may be useful, for example, for constructing LaTeX tables.

References

See Also
ftable for more information on flat contingency tables.

Examples

```r
## Agresti (1990), page 157, Table 5.8.
## Not in ftable standard format, but o.k.
file <- tempfile()
cat("Intercourse\n", "Race Gender Yes No\n", "White Male 43 134\n", " Female 26 149\n", "Black Male 29 23\n", " Female 22 36\n", file = file)
file.show(file)
ft1 <- read.ftable(file)
ft1 unlink(file)

## Agresti (1990), page 297, Table 8.16.
```

## Almost o.k., but misses the name of the row variable.

```r
defile <- tempfile()
cat(" "
    "Tonsil Size"
    "Not Enl." "Enl." "Greatly Enl." 
    "Noncarriers 497 560 269"
    "Carriers 19 29 24"
  file = file
file.show(file)
ft <- read.ftable(file, skip = 2,
  row.var.names = "Status",
  col.vars = list("Tonsil Size" = 
      c("Not Enl.", "Enl.", "Greatly Enl.")))  
ft
unlink(file)

ft22 <- ftable(Titanic, row.vars = 2:1, col.vars = 4:3)
write.ftable(ft22, quote = FALSE)
write.ftable(ft22, quote = FALSE, method="row.compact")
write.ftable(ft22, quote = FALSE, method="col.compact")
write.ftable(ft22, quote = FALSE, method="compact")
```

---

### rect.hclust

**Draw Rectangles Around Hierarchical Clusters**

**Description**

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

**Usage**

```r
rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
        border = 2, cluster = NULL)
```

**Arguments**

- **tree**: an object of the type produced by `hclust`.
- **k, h**: Scalar. Cut the dendrogram such that either exactly k clusters are produced or by cutting at height h.
- **which, x**: A vector selecting the clusters around which a rectangle should be drawn. which selects clusters by number (from left to right in the tree), x selects clusters containing the respective horizontal coordinates. Default is which = 1:k.
- **border**: Vector with border colors for the rectangles.
- **cluster**: Optional vector with cluster memberships as returned by `cutree(hclust.obj, k = k)`, can be specified for efficiency if already computed.

**Value**

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.)
See Also

\texttt{hclust}, \texttt{identify.hclust}.

Examples

```r
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k = 3, border = "red")
x <- rect.hclust(hca, h = 50, which = c(2,7), border = 3:4)
x
```

relevel

\textit{Reorder Levels of Factor}

Description

The levels of a factor are re-ordered so that the level specified by \texttt{ref} is first and the others are moved down. This is useful for \texttt{contr.treatment} contrasts which take the first level as the reference.

Usage

```r
relevel(x, ref, ...)
```

Arguments

- \texttt{x} an unordered factor.
- \texttt{ref} the reference level, typically a string.
- \texttt{...} additional arguments for future methods.

Details

This, as \texttt{reorder()}, is a special case of simply calling \texttt{factor(x, levels = levels(x)[....]).}

Value

A factor of the same length as \texttt{x}.

See Also

\texttt{factor, contr.treatment, levels, reorder}.

Examples

```r
warpbreaks$tension <- relevel(warpbreaks$tension, ref = "M")
summary(lm(breaks ~ wool + tension, data = warpbreaks))
```
reorder.default  Reorder Levels of a Factor

Description

reorder is a generic function. The "default" method treats its first argument as a categorical variable, and reorders its levels based on the values of a second variable, usually numeric.

Usage

reorder(x, ...)

## Default S3 method:
reorder(x, X, FUN = mean, ...,
       order = is.ordered(x))

Arguments

- `x` an atomic vector, usually a factor (possibly ordered). The vector is treated as a categorical variable whose levels will be reordered. If `x` is not a factor, its unique values will be used as the implicit levels.
- `X` a vector of the same length as `x`, whose subset of values for each unique level of `x` determines the eventual order of that level.
- `FUN` a function whose first argument is a vector and returns a scalar, to be applied to each subset of `X` determined by the levels of `x`.
- `...` optional: extra arguments supplied to `FUN`
- `order` logical, whether return value will be an ordered factor rather than a factor.

Details

This, as `relevel()`, is a special case of simply calling `factor(x, levels = levels(x)[....])`.

Value

A factor or an ordered factor (depending on the value of `order`), with the order of the levels determined by `FUN` applied to `X` grouped by `x`. The levels are ordered such that the values returned by `FUN` are in increasing order. Empty levels will be dropped.

Additionally, the values of `FUN` applied to the subsets of `X` (in the original order of the levels of `x`) is returned as the "scores" attribute.

Deepayan Sarkar <deepayan.sarkar@r-project.org>

See Also

`reorder.dendrogram, levels, relevel.`
Examples

```r
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
       xlab = "Type of spray", ylab = "Insect count",
       main = "InsectSprays data", varwidth = TRUE,
       col = "lightgray")
```

reorder.dendrogram

Reorder a Dendrogram

Description

A method for the generic function `reorder`.

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

Usage

```r
reorder(x, wts, agglo.FUN = sum, ...)
```

Arguments

- `x`: the (dendrogram) object to be reordered
- `wts`: numeric weights (arbitrary values) for reordering.
- `agglo.FUN`: a function for weights agglomeration, see below.
- `...`: additional arguments

Details

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as $f(w_j)$ where $f$ is `agglo.FUN` and $w_j$ is the weight of the $j$-th sub branch).

Value

A dendrogram where each node has a further attribute `value` with its corresponding weight.

Author(s)

R. Gentleman and M. Maechler

See Also

- `reorder`
- `rev.dendrogram` which simply reverses the nodes’ order; `heatmap`, `cophenetic`. 
Examples

```r
require(graphics)

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN = mean), main = "reorder(dd, 10:1, mean)")
par(op)
```

---

replications

<table>
<thead>
<tr>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns a vector or a list of the number of replicates for each term in the formula.</td>
</tr>
</tbody>
</table>

Usage

```r
replications(formula, data = NULL, na.action)
```

Arguments

- `formula`: a formula or a terms object or a data frame.
- `data`: a data frame used to find the objects in `formula`.
- `na.action`: function for handling missing values. Defaults to a `na.action` attribute of `data`, then a setting of the option `na.action`, or `na.fail` if that is not set.

Details

If `formula` is a data frame and `data` is missing, `formula` is used for `data` with the formula `~ ..`. Any character vectors in the formula are coerced to factors.

Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula, data))`.

Author(s)

The design was inspired by the S function of the same name described in Chambers *et al* (1992).
reshape

Description

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

Usage

```
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
        idvar = "id", ids = 1:NROW(data),
        times = seq_along(varying[[1]]),
        drop = NULL, direction, new.row.names = NULL,
        sep = ".",
        split = if (sep == "") {
            list(regexp = "[A-Za-z][0-9]", include = TRUE)
        } else {
            list(regexp = sep, include = FALSE, fixed = TRUE)
        })
```

Arguments

- `data`: a data frame
- `varying`: names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indices which are interpreted as referring to `names(data)`. See ‘Details’ for more details and options.

Examples

```r
N <- c(0,1,0,1,1,1,0,0,1,1,0,0,1,0,1,0,1,0,1,1,1,0,1,1,0,1,0)
P <- c(1,1,0,0,0,1,0,1,1,1,0,0,0,1,0,1,1,0,0,1,1,1,0,1,0,1,0)
K <- c(1,0,0,1,0,1,0,1,0,1,1,0,0,1,0,1,1,0,0,1,1,1,0,1,0,1,0)
yield <- c(49.5,62.8,46.8,57.0,59.8,58.5,55.5,56.0,62.8,55.8,69.5,
          55.0, 62.0,48.8,45.5,44.2,52.0,51.5,49.8,48.8,57.2,59.0,53.2,56.0)
npk <- data.frame(block = gl(6,4), N = factor(N), P = factor(P),
                   K = factor(K), yield = yield)
replications(~ . - yield, npk)
```
v.names
names of variables in the long format that correspond to multiple variables in the wide format. See 'Details'.
timevar
the variable in long format that differentiates multiple records from the same group or individual. If more than one record matches, the first will be taken (with a warning).
idvar
Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format.
ids
the values to use for a newly created idvar variable in long format.
times
the values to use for a newly created timevar variable in long format. See ‘Details’.
drop
a vector of names of variables to drop before reshaping.
direction
character string, partially matched to either "wide" to reshape to wide format, or "long" to reshape to long format.
new.row.names
character or NULL: a non-null value will be used for the row names of the result.
sep
A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing v.names and times arguments based on the names in varying. If sep == "", the split is just before the first numeral that follows an alphabetic character. This is also used to create variable names when reshaping to wide format.
split
A list with three components, regexp, include, and (optionally) fixed. This allows an extended interface to variable name splitting. See ‘Details’.

Details
The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A ‘wide’ longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In ‘long’ format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A ‘long’ format dataset also needs a ‘time’ variable identifying which time point each record comes from and an ‘id’ variable showing which records refer to the same person.

If the data frame resulted from a previous reshape then the operation can be reversed simply by reshape(a). The direction argument is optional and the other arguments are stored as attributes on the data frame.

If direction = "wide" and no varying or v.names arguments are supplied it is assumed that all variables except idvar and timevar are time-varying. They are all expanded into multiple variables in wide format.

If direction = "long" the varying argument can be a vector of column names (or a corresponding index). The function will attempt to guess the v.names and times from these names. The default is variable names like x.1, x.2, where sep = "." specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use sep = "".

Variable name splitting as described above is only attempted in the case where varying is an atomic vector, if it is a list or a matrix, v.names and times will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if v.names is given explicitly. Notice that the order of variables in varying is like x.1.y.1.x.2.y.2.

The split argument should not usually be necessary. The split$regexp component is passed to either strsplit or regexpr, where the latter is used if split$include is TRUE, in which case the
splitting occurs after the first character of the matched string. In the `strsplit` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

**Value**

The reshaped data frame with added attributes to simplify reshaping back to the original form.

**See Also**

`stack`, `aperm`, `relist` for reshaping the result of `unlist`.

**Examples**

```r
summary(Indometh)
wide <- reshape(Indometh, v.names = "conc", idvar = "Subject",
               timevar = "time", direction = "wide")
wide

reshape(wide, direction = "long")
reshape(wide, idvar = "Subject", varying = list(2:12),
        v.names = "conc", direction = "long")

## times need not be numeric
df <- data.frame(id = rep(1:4, rep(2,4)),
                  visit = I(rep(c("Before","After"), 4)),
                  x = rnorm(4), y = runif(4))
df
reshape(df, timevar = "visit", idvar = "id", direction = "wide")
## warns that y is really varying
reshape(df, timevar = "visit", idvar = "id", direction = "wide", v.names = "x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7, ]
df2
reshape(df2, timevar = "visit", idvar = "id", direction = "wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id = 1:4, age = c(40,50,60,50), dose1 = c(1,2,1,2),
                  dose2 = c(2,1,2,1), dose4 = c(3,3,3,3))
reshape(df3, direction = "long", varying = 3:5, sep = "")

## an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar = "state", ids = row.names(state.x77),
                times = names(state.x77), timevar = "Characteristic",
                varying = list(names(state.x77)), direction = "long")
reshape(long, direction = "wide")
reshape(long, direction = "wide", new.row.names = unique(long$state))

## multiple id variables
df3 <- data.frame(school = rep(1:3, each = 4), class = rep(9:10, 6),
                  time = rep(c(1,1,2,2), 3), score = rnorm(12))
wide <- reshape(df3, idvar = c("school","class"), direction = "wide")
```
residuals

wide
## transform back
reshape(wide)

residuals Extract Model Residuals

Description
residuals is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form resid is an alias for residuals. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a residuals method. (Note that the method is for 'residuals' and not 'resid'.)

Methods can make use of naresid methods to compensate for the omission of missing values. The default, nls and smooth.spline methods do.

Usage
residuals(object, ...)
resid(object, ...)

Arguments

object an object for which the extraction of model residuals is meaningful.
...
other arguments.

Value
Residuals extracted from the object object.

References

coefficients, fitted.values, glm, lm.
influence.measures for standardized (rstandard) and studentized (rstudent) residuals.
runmed

Running Medians – Robust Scatter Plot Smoothing

Description

Compute running medians of odd span. This is the ‘most robust’ scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

Usage

runmed(x, k, endrule = c("median", "keep", "constant"),
algorithm = NULL, print.level = 0)

Arguments

x numeric vector, the ‘dependent’ variable to be smoothed.

k integer width of median window; must be odd. Turlach had a default of
k <- 1 + 2 * min((n-1)%/% 2, ceiling(0.1*n)). Use k = 3 for ‘minimal’
robust smoothing eliminating isolated outliers.

derule character string indicating how the values at the beginning and the end (of the
data) should be treated. Can be abbreviated. Possible values are:
"keep" keeps the first and last k2 values at both ends, where k2 is the half-
bandwidth k2 = k %/% 2, i.e., y[j] = x[j] for j ∈ {1,...,k2; n−k2 + 1,...,n};
"constant" copies median(y[1:k2]) to the first values and analogously for
the last ones making the smoothed ends constant;
"median" the default, smooths the ends by using symmetrical medians of sub-
sequently smaller bandwidth, but for the very first and last value where
Tukey’s robust end-point rule is applied, see smoothEnds.

algorithm character string (partially matching "Turlach" or "Stuetzle") or the default NULL, specifying which algorithm should be applied. The default choice depends
on n = length(x) and k where “Turlach” will be used for larger problems.

print.level integer, indicating verboseness of algorithm; should rarely be changed by average users.

Details

Apart from the end values, the result y = runmed(x, k) simply has
y[j] = median(x[(j−k2):(j+k2)]) (k = 2*k2+1), computed very efficiently.

The two algorithms are internally entirely different:

"Turlach" is the Härdle–Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A
tree algorithm is used, ensuring performance O(n log k) where n = length(x) which is
asymptotically optimal.

"Stuetzle" is the (older) Stuetzle–Friedman implementation which makes use of median updating
when one observation enters and one leaves the smoothing window. While this performs as
O(n × k) which is slower asymptotically, it is considerably faster for small k or n.

Currently long vectors are only supported for algorithm = "Steutzle".
runmed

Value
vector of smoothed values of the same length as x with an attribute k containing (the ‘oddified’) k.

Author(s)
Martin Maechler <maechler@stat.math.ethz.ch>, based on Fortran code from Werner Stuetzle and S-PLUS and C code from Berwin Turlach.

References

See Also
smoothEnds which implements Tukey’s end point rule and is called by default from runmed(*, endrule = ”median”). smooth uses running medians of 3 for its compound smoothers.

Examples
require(graphics)

y [c(1,10,21,41)] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighborhood <=> interpolation
plot(y) ## lines(y, lwd = .1, col = "light gray")
lines(lowess(seq(y), y, f = 0.3), col = "brown")
lines(runmed(y, 7), lwd = 2, col = "blue")
lines(runmed(y, 11), lwd = 2, col = "red")

## Lowess is not robust
y <- ys ; y[21] <- 6666 ; x <- seq(y)
col <- c("black", "brown","blue")
plot(y, col = col[1])
lines(lowess(x, y, f = 0.3), col = col[2])
Description

Generate $n$ random matrices, distributed according to the Wishart distribution with parameters $\Sigma$ and $df$, $W_p(\Sigma, m)$, $m = df$, $\Sigma = \text{Sigma}$.

Usage

```r
rWishart(n, df, Sigma)
```

Arguments

- **n**: integer sample size.
- **df**: numeric parameter, “degrees of freedom”.
- **Sigma**: positive definite ($p \times p$) “scale” matrix, the matrix parameter of the distribution.

Details

If $X_1, \ldots, X_m, X_i \in \mathbb{R}^p$ is a sample of $m$ independent multivariate Gaussians with mean (vector) 0, and covariance matrix $\Sigma$, the distribution of $M = X'X$ is $W_p(\Sigma, m)$.

Consequently, the expectation of $M$ is

$$E[M] = m \times \Sigma.$$ 

Further, if $\text{Sigma}$ is scalar ($p = 1$), the Wishart distribution is a scaled chi-squared ($\chi^2$) distribution with $df$ degrees of freedom, $W_1(\sigma^2, m) = \sigma^2 \chi_m^2$.

The component wise variance is

$$\text{Var}(M_{ij}) = m(\Sigma_{ij}^2 + \Sigma_{ii} \Sigma_{jj}).$$

Value

A numeric array, say $R$, of dimension $p \times p \times n$, where each $R[,,i]$ is a positive definite matrix, a realization of the Wishart distribution $W_p(\Sigma, m)$, $m = df$, $\Sigma = \text{Sigma}$.

vR <- apply(R, 1:2, var)
stopifnot(all.equal(vR, Va, tolerance = 1/16))

scatter.smooth

Scatter Plot with Smooth Curve Fitted by Loess

Description

Plot and add a smooth curve computed by loess to a scatter plot.

Usage

scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
family = c("symmetric", "gaussian"),
xlab = NULL, ylab = NULL,
ylim = range(y, pred$y, na.rm = TRUE),
evaluation = 50, ..., lpars = list())

loess.smooth(x, y, span = 2/3, degree = 1,
family = c("symmetric", "gaussian"), evaluation = 50, ...)

Arguments

x, y the x and y arguments provide the x and y coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details.

span smoothness parameter for loess.

degree degree of local polynomial used.

family if "gaussian" fitting is by least-squares, and if family = "symmetric" a re-descending M estimator is used. Can be abbreviated.

xlab label for x axis.

ylab label for y axis.

ylim the y limits of the plot.

evaluation number of points at which to evaluate the smooth curve.

... For scatter.smooth(), graphical parameters, passed to plot() only. For loess.smooth, control parameters passed to loess.control.

lpars a list of arguments to be passed to lines().
Details

loess.smooth is an auxiliary function which evaluates the loess smooth at evaluation equally spaced points covering the range of x.

Value

For scatter.smooth, none.

For loess.smooth, a list with two components, x (the grid of evaluation points) and y (the smoothed values at the grid points).

See Also

loess; smoothScatter for scatter plots with smoothed density color representation.

Examples

require(graphics)

with(cars, scatter.smooth(speed, dist))
## or with dotted thick smoothed line results :
with(cars, scatter.smooth(speed, dist, lpars =
    list(col = "red", lwd = 3, lty = 3)))

Description

screeplot.default plots the variances against the number of the principal component. This is also the plot method for classes "princomp" and "prcomp".

Usage

## Default S3 method:
screeplot(x, npcs = min(10, length(x$sdev)),
    type = c("barplot", "lines"),
    main = deparse(substitute(x)), ...)

Arguments

x an object containing a sdev component, such as that returned by princomp() and prcomp().
npcs the number of components to be plotted.
type the type of plot. Can be abbreviated.
main, ... graphics parameters.

References

See Also

princomp and prcomp.

Examples

```r
require(graphics)

## The variances of the variables in the
## USArrests data vary by orders of magnitude, so scaling is appropriate
(pc.cr <- princomp(USArrests, cor = TRUE)) # inappropriate
screeplot(pc.cr)

fit <- princomp(covmat = Harman74.cor)
screeplot(fit)
screeplot(fit, npcs = 24, type = "lines")
```

---

### sd

**Standard Deviation**

This function computes the standard deviation of the values in `x`. If `na.rm` is `TRUE` then missing values are removed before computation proceeds.

**Usage**

```r
sd(x, na.rm = FALSE)
```

**Arguments**

- `x` a numeric vector or an R object which is coercible to one by `as.double(x)`.
- `na.rm` logical. Should missing values be removed?

**Details**

Like `var` this uses denominator \( n - 1 \).

The standard deviation of a zero-length vector (after removal of NAs if `na.rm = TRUE`) is not defined and gives an error. The standard deviation of a length-one vector is NA.

**See Also**

- `var` for its square, and `mad`, the most robust alternative.

**Examples**

```r
sd(1:2) ^ 2
```
se.contrast

Standard Errors for Contrasts in Model Terms

Description

Returns the standard errors for one or more contrasts in an aov object.

Usage

se.contrast(object, ...)
## S3 method for class 'aov'
se.contrast(object, contrast.obj,
            coef = contr.helmert(ncol(contrast))[, 1],
            data = NULL, ...)

Arguments

object A suitable fit, usually from aov.
contrast.obj The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
coef used when contrast.obj is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.
data The data frame used to evaluate contrast.obj.
... further arguments passed to or from other methods.

Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use se.contrast than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for aov about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with coef can be found by calling contrasts and indexing the columns by a factor.

Value

A vector giving the standard errors for each contrast.

selfStart  

Construct Self-starting Nonlinear Models

Description

Construct self-starting nonlinear models to be used in nls, etc. Via function initial to compute approximate parameter values from data, such models are “self-starting”, i.e., do not need a start argument in, e.g., nls().

Usage

selfStart(model, initial, parameters, template)

Arguments

model  
a function object defining a nonlinear model or a nonlinear formula object of the form ~ expression.

initial  
a function object, taking three arguments: mCall, data, and LHS, representing, respectively, a matched call to the function model, a data frame in which to interpret the variables in mCall, and the expression from the left-hand side of the model formula in the call to nls. This function should return initial values for the parameters in model.

parameters  
a character vector specifying the terms on the right hand side of model for which initial estimates should be calculated. Passed as the namevec argument to the deriv function.

template  
an optional prototype for the calling sequence of the returned object, passed as the function.arg argument to the deriv function. By default, a template is generated with the covariates in model coming first and the parameters in model coming last in the calling sequence.

Details

nls() calls getInitial and the initial function for these self-starting models.

This function is generic; methods functions can be written to handle specific classes of objects.

Value

a function object of class "selfStart", for the formula method obtained by applying deriv to the right hand side of the model formula. An initial attribute (defined by the initial argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

Author(s)

José Pinheiro and Douglas Bates

See Also

nls, getInitial.

Each of the following are "selfStart" models (with examples) SSasymp, SSasympOff, SSasympOrig, SSbiexp, SSfol, SSfpl, SSgompertz, SSlogis, SSmicmen, SSweibull.

Further, package nlme’s nlsList.
Examples

### self-starting logistic model

```r
## The "initializer" (finds initial values for parameters from data):
initLogis <- function(mCall, data, LHS) {
  xy <- data.frame(sortedXyData(mCall[["input"]], LHS, data))
  if(nrow(xy) < 4)
    stop("too few distinct input values to fit a logistic model")
  z <- xy["y"]
  ## transform to proportion, i.e. in (0,1):
  rng <- range(z); dz <- diff(rng)
  z <- (z - rng[1L] + 0.05 * dz)/(1.1 * dz)
  xy["z"] <- log(z/(1 - z)) # logit transformation
  aux <- coef(lm(x ~ z, xy))
  pars <- coef(nls(y ~ 1/(1 + exp((xmid - x)/scal)),
                   data = xy,
                   start = list(xmid = aux[[1L]], scal = aux[[2L]]),
                   algorithm = "plinear"))
  setNames(pars[c(".lin", "xmid", "scal")], nm = mCall[c("Asym", "xmid", "scal")])
}

SSlogis <- selfStart(~ Asym/(1 + exp((xmid - x)/scal)),
                      initial = initLogis,
                      parameters = c("Asym", "xmid", "scal"))
```

First-order logistic model

```r
SSfol <- selfStart(first.order.log.model, first.order.log.initial)
```

Explore the self-starting models already available in R's `stats`:

```r
pos.st <- which("package:stats" == search())
msS <- apropos("^SS..", where = TRUE, ignore.case = FALSE)
(msS <- unname(msS[names(msS) == pos.st]))
fS <- sapply(msS, get, pos = pos.st, mode = "function")
all(sapply(fS, inherits, "selfStart")) # -> TRUE
```

Show the argument list of each self-starting function:

```r
str(fS, give.attr = FALSE)
```

---

### setNames

**Set the Names in an Object**

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.
Usage

setNames(object = nm, nm)

Arguments

  object      an object for which a names attribute will be meaningful
  nm          a character vector of names to assign to the object

Value

  An object of the same sort as object with the new names assigned.

Author(s)

  Douglas M. Bates and Saikat DebRoy

See Also

  unname for removing names.

Examples

  setNames( 1:3, c("foo", "bar", "baz") )
  # this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp

  ## special case of character vector, using default
setNames(nm = c("First", "2nd"))

shapiro.test  Shapiro-Wilk Normality Test

Description

  Performs the Shapiro-Wilk test of normality.

Usage

  shapiro.test(x)

Arguments

  x          a numeric vector of data values. Missing values are allowed, but the number of
             non-missing values must be between 3 and 5000.
Value

A list with class "htest" containing the following components:

- **statistic**: the value of the Shapiro-Wilk statistic.
- **p.value**: an approximate p-value for the test. This is said in Royston (1995) to be adequate for \( p \text{.value} < 0.1 \).
- **method**: the character string "Shapiro-Wilk normality test".
- **data.name**: a character string giving the name(s) of the data.

Source

The algorithm used is a C translation of the Fortran code described in Royston (1995). The calculation of the p value is exact for \( n = 3 \), otherwise approximations are used, separately for \( 4 \leq n \leq 11 \) and \( n \geq 12 \).

References

See Also

- `qqnorm` for producing a normal quantile-quantile plot.

Examples

```r
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

### sigma

**Extract Residual Standard Deviation 'Sigma'**

**Description**

Extract the estimated standard deviation of the errors, the “residual standard deviation” (misnomed also “residual standard error”, e.g., in `summary.lm()`’s output, from a fitted model).

Many classical statistical models have a *scale parameter*, typically the standard deviation of a zero-mean normal (or Gaussian) random variable which is denoted as \( \sigma \). `sigma(.)` extracts the *estimated* parameter from a fitted model, i.e., \( \hat{\sigma} \).

**Usage**

```r
sigma(object, ...)  # Default S3 method:
sigma(object, use.fallback = TRUE, ...)
```
Arguments

- **object**: an R object, typically resulting from a model fitting function such as `lm`.
- **use.fallback**: logical, passed to `nobs`.
- **...**: potentially further arguments passed to and from methods. Passed to `deviance(*, ...)` for the default method.

Details

The `stats` package provides the S3 generic and a default method. The latter is correct typically for (asymptotically / approximately) generalized gaussian (“least squares”) problems, since it is defined as

\[
\text{sigma.default} <- \text{function (object, use.fallback = TRUE, ...)}
\]

\[
\textrm{sqrt( deviance(object, ...) / (NN - PP) )}
\]

where \( NN \) <- `nobs(object, use.fallback = use.fallback)` and \( PP \) <- `sum(!is.na(coef(object)))` – where in older R versions this was `length(coef(object))` which is too large in case of undetermined coefficients, e.g., for rank deficient model fits.

Value

Typically a number, the estimated standard deviation of the errors (“residual standard deviation”) for Gaussian models, and—less interpretably—the square root of the residual deviance per degree of freedom in more general models. In some generalized linear modelling (glm) contexts, \( \text{sigma}^2 \) (\( \text{sigma}(.)^2 \)) is called “dispersion (parameter)”. Consequently, for well-fitting binomial or Poisson GLMs, \( \text{sigma} \) is around 1.

Very strictly speaking, \( \hat{\sigma} \) (“\( \sigma \) hat”) is actually \( \sqrt{\hat{\sigma}^2} \).

For multivariate linear models (class "mlm"), a vector of sigmas is returned, each corresponding to one column of \( Y \).

Note

The misnomer “Residual standard error” has been part of too many R (and S) outputs to be easily changed there.

See Also

`deviance`, `nobs`, `vcov`.

Examples

```r
## -- lm() ------------------------------
lm1 <- lm(Fertility ~ . , data = swiss)
sigma(lm1) # ~= 7.165 = "Residual standard error" printed from summary(lm1)
stopifnot(all.equal(sigma(lm1), summary(lm1)$sigma, tol=1e-15))
## -- nls() -----------------------------
DNase1 <- subset(DNase, Run == 1)
fm.DN1 <- nls(density ~ SSlogis(log(conc), Asym, xmid, scal), DNase1)
sigma(fm.DN1) # ~= 0.01919 as from summary(..)
```
SignRank

Distribution of the Wilcoxon Signed Rank Statistic

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size \( n \).

Usage

\[
\text{dsignrank}(x, n, \text{log} = \text{FALSE}) \\
\text{psignrank}(q, n, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \\
\text{qsignrank}(p, n, \text{lower.tail} = \text{TRUE}, \text{log.p} = \text{FALSE}) \\
\text{rsignrank}(nn, n)
\]

Arguments

\( x, q \)  
vector of quantiles.

\( p \)  
vector of probabilities.

\( nn \)  
number of observations. If \( \text{length}(nn) > 1 \), the length is taken to be the number required.

\( n \)  
number(s) of observations in the sample(s). A positive integer, or a vector of such integers.
log, log.p logical; if TRUE, probabilities p are given as \( \log(p) \).
lower.tail logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

This distribution is obtained as follows. Let \( x \) be a sample of size \( n \) from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values \( x[i] \) for which \( x[i] \) is positive. This statistic takes values between 0 and \( n(n+1)/2 \), and its mean and variance are \( n(n+1)/4 \) and \( n(n+1)(2n+1)/24 \), respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

Value
dsignrank gives the density, psignrank gives the distribution function, qsignrank gives the quantile function, and rsignrank generates random deviates.

The length of the result is determined by \( nn \) for rsignrank, and is the maximum of the lengths of the numerical arguments for the other functions.
The numerical arguments other than \( nn \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Author(s)
Kurt Hornik; efficiency improvement by Ivo Ugrina.

See Also
wilcox.test to calculate the statistic from data, find p values and so on.
Distributions for standard distributions, including dwilcox for the distribution of two-sample Wilcoxon rank sum statistic.

Examples

```r
require(graphics)
par(mfrow = c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length = 501)
  plot(x, dsignrank(x, n = n), type = "l",
       main = paste0("dsignrank(x, n = ", n, ", ")")
}
```

simulate

### Simulate Responses

**Description**

Simulate one or more responses from the distribution corresponding to a fitted model object.
Usage

simulate(object, nsim = 1, seed = NULL, ...)

Arguments

- **object**: an object representing a fitted model.
- **nsim**: number of response vectors to simulate. Defaults to 1.
- **seed**: an object specifying if and how the random number generator should be initialized ("seeded"). For the "lm" method, either NULL or an integer that will be used in a call to `set.seed` before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return `.Random.seed` as the "seed" attribute, see 'Value'.
- **...**: additional optional arguments.

Details

This is a generic function. Consult the individual modeling functions for details on how to use this function.

Package **stats** has a method for "lm" objects which is used for `lm` and `glm` fits. There is a method for fits from `glm.nb` in package **MASS**, and hence the case of negative binomial families is not covered by the "lm" method.

The methods for linear models fitted by `lm` or `glm(family = "gaussian")` assume that any weights which have been supplied are inversely proportional to the error variance. For other GLMs the (optional) `simulate` component of the `family` object is used—there is no appropriate simulation method for 'quasi' models as they are specified only up to two moments.

For binomial and Poisson GLMs the dispersion is fixed at one. Integer prior weights $w_i$ can be interpreted as meaning that observation $i$ is an average of $w_i$ observations, which is natural for binomials specified as proportions but less so for a Poisson, for which prior weights are ignored with a warning.

For a gamma GLM the shape parameter is estimated by maximum likelihood (using function `gamma.shape` in package **MASS**). The interpretation of weights is as multipliers to a basic shape parameter, since dispersion is inversely proportional to shape.

For an inverse gaussian GLM the model assumed is $IG(\mu_i, \lambda w_i)$ (see [https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution](https://en.wikipedia.org/wiki/Inverse_Gaussian_distribution)) where $\lambda$ is estimated by the inverse of the dispersion estimate for the fit. The variance is $\mu_i^3/(\lambda w_i)$ and hence inversely proportional to the prior weights. The simulation is done by function `rinvGauss` from the **SuppDists** package, which must be installed.

Value

Typically, a list of length `nsim` of simulated responses. Where appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed". If argument `seed` is `NULL`, the attribute is the value of `.Random.seed` before the simulation was started; otherwise it is the value of the argument with a "kind" attribute with value `as.list(RNGkind())`.

smooth Tukey’s (Running Median) Smoothing

Description

Tukey’s smoothers, 3RS3R, 3RSS, 3R, etc.

Usage

smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
       twiceit = FALSE, endrule = c(\"Tukey\", \"copy\"), do.ends = FALSE)
smooth

Arguments

x a vector or time series
kind a character string indicating the kind of smoother required; defaults to "3RS3R".
twiceit logical, indicating if the result should be ‘twiced’. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$, i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance).
endrule a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".
do.ends logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for kind = "S".

Details

3 is Tukey’s short notation for running medians of length 3, 3R stands for Repeated 3 until convergence, and S for Splitting of horizontal stretches of length 2 or 3. Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then (S and 3) Repeated until convergence – which can be bad.

Value

An object of class "tukeysmooth" (which has print and summary methods) and is a vector or time series containing the smoothed values with additional attributes.

Note

S and S-PLUS use a different (somewhat better) Tukey smoother in smooth(*). Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.
Since R version 1.2, smooth does really implement Tukey’s end-point rule correctly (see argument endrule).
kind = "3RSR" has been the default till R-1.1, but it can have very bad properties, see the examples.
Note that repeated application of smooth(*) does smooth more, for the "3RS*" kinds.

smooth.spline  

*Fit a Smoothing Spline*

**Description**

Fits a cubic smoothing spline to the supplied data.

**Usage**

```r
smooth.spline(x, y = NULL, w = NULL, df, spar = NULL, lambda = NULL, cv = FALSE,  
  all.knots = FALSE, nknots = .nknots.smspl,  
  keep.data = TRUE, df.offset = 0, penalty = 1,  
  control.spar = list(), tol = 1e-6 * IQR(x), keep.stuff = FALSE)
```

**Arguments**

- **x**
  - a vector giving the values of the predictor variable, or a list or a two-column matrix specifying x and y.
- **y**
  - responses. If y is missing or NULL, the responses are assumed to be specified by x, with x the index vector.
- **w**
  - optional vector of weights of the same length as x; defaults to all 1.
- **df**
  - the desired equivalent number of degrees of freedom (trace of the smoother matrix). Must be in \([1, n_x]\), \(n_x\) the number of unique x values, see below.
- **spar**
  - smoothing parameter, typically (but not necessarily) in \((0, 1]\). When spar is specified, the coefficient \(\lambda\) of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of spar, see the
smooth.spline

details below. Alternatively lambda may be specified instead of the scale free spar=s.

lambda
if desired, the internal (design-dependent) smoothing parameter \( \lambda \) can be specified instead of spar. This may be desirable for resampling algorithms such as cross validation or the bootstrap.

cv
ordinary leave-one-out (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE; is used for smoothing parameter computation only when both spar and df are not specified; it is used however to determine cv.crit in the result. Setting it to NA for speedup skips the evaluation of leverages and any score.

all.knots
if TRUE, all distinct points in x are used as knots. If FALSE (default), a subset of x[] is used, specifically x[j] where the nknots indices are evenly spaced in 1:n, see also the next argument nknots. Alternatively, a strictly increasing numeric vector specifying “all the knots” to be used; must be rescaled to [0,1] already such that it corresponds to the ans $ fit$knots sequence returned, not repeating the boundary knots.

nknots
integer or function giving the number of knots to use when all.knots = FALSE. If a function (as by default), the number of knots is nknots(nx). By default for \( n_x > 49 \) this is less than \( n_x \), the number of unique x values, see the Note.

keep.data
logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.

df.offset
allows the degrees of freedom to be increased by df.offset in the GCV criterion.

penalty
the coefficient of the penalty for degrees of freedom in the GCV criterion.

control.spar
optional list with named components controlling the root finding when the smoothing parameter spar is computed, i.e., missing or NULL, see below.

Note that this is partly experimental and may change with general spar computation improvements!

low:
lower bound for spar; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).

high:
upper bound for spar; defaults to +1.5.

tol:
the absolute precision (tolerance) used; defaults to 1e-4 (formerly 1e-3).

eps:
the relative precision used; defaults to 2e-8 (formerly 0.00244).

trace:
logical indicating if iterations should be traced.

maxit:
integer giving the maximal number of iterations; defaults to 500.

Note that spar is only searched for in the interval \([low, high]\).

tol:
a tolerance for same-ness or uniqueness of the x values. The values are binned into bins of size tol and values which fall into the same bin are regarded as the same. Must be strictly positive (and finite).

keep.stuff
an experimental logical indicating if the result should keep extras from the internal computations. Should allow to reconstruct the \( X \) matrix and more.

Details

Neither x nor y are allowed to containing missing or infinite values.
The x vector should contain at least four distinct values. ‘Distinct’ here is controlled by tol: values which are regarded as the same are replaced by the first of their values and the corresponding y and w are pooled accordingly.
Unless lambda has been specified instead of spar, the computational \( \lambda \) used (as a function of \( s = \text{spar} \)) is \( \lambda = r \ast 2563^{s-1} \) where \( r = \text{tr}(X'WX)/\text{tr}(\Sigma) \), \( \Sigma \) is the matrix given by \( \Sigma_{ij} = \int B_i''(t)B_j''(t)dt \), \( X \) is given by \( X_{ij} = B_j(x_i) \), \( W \) is the diagonal matrix of weights (scaled such that its trace is \( n \), the original number of observations) and \( B_k(\cdot) \) is the \( k \)-th B-spline.

Note that with these definitions, \( f = Xc \) (i.e., \( c \) is the vector of spline coefficients), the penalized log likelihood is only if data
\[ L = (y - f)'W(y - f) + \lambda c'\Sigma c, \]
and hence \( c \) is the solution of the (ridge regression) \( (X'WX + \lambda\Sigma)c = X'Wy \).

If spar and lambda are missing or NULL, the value of df is used to determine the degree of smoothing. If df is missing as well, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by cv) is used to determine \( \lambda \).

Note that from the above relation, spar is \( s = s0 + 0.0601 \ast \log \lambda \), which is intentionally different from the S-PLUS implementation of smooth.spline (where spar is proportional to \( \lambda \)). In R’s (log \( \lambda \)) scale, it makes more sense to vary spar linearly.

Note however that currently the results may become very unreliable for spar values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting spar or the controls low and high outside such a safe range, unless you know what you are doing! Similarly, specifying lambda instead of spar is delicate, notably as the range of “safe” values for lambda is not scale-invariant and hence entirely data dependent.

The ‘generalized’ cross-validation method GCV will work correctly when there are duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. cv = TRUE is best avoided in that case.

### Value

An object of class ”smooth.spline” with components

- \( x \): the distinct \( x \) values in increasing order, see the ‘Details’ above.
- \( y \): the fitted values corresponding to \( x \).
- \( w \): the weights used at the unique values of \( x \).
- \( yin \): the \( y \) values used at the unique \( y \) values.
- \( tol \): the tol argument (whose default depends on \( x \)).
- \( data \): only if keep.data = TRUE: itself a list with components \( x \), \( y \), and \( w \) of the same length. These are the original \( (x_i,y_i,w_i), i = 1, \ldots, n \), values where data \( x \) may have repeated values and hence be longer than the above \( x \) component; see details.
- \( lev \): (when cv was not NA) leverages, the diagonal values of the smoother matrix.
- \( cv.crit \): cross-validation score, ‘generalized’ or true, depending on cv. The CV score is often called “PRESS” (and labeled on print()), for ‘PREdiction Sum of Squares’.
- \( pen.crit \): the penalized criterion, a non-negative number; simply the (weighted) residual sum of squares (RSS), \( \text{sum}(\cdot w \ast \text{residuals(\cdot)}^2) \).
- \( crit \): the criterion value minimized in the underlying Fortran routine ‘sslvrg’. When df has been specified, the criterion is \( 3 + (\text{tr}(S_\lambda) - df)^2 \), where the 3+ is there for numerical (and historical) reasons.
- \( df \): equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true df is between 1 and 2.
spar
the value of spar computed or given, unless it has been given as c(lambda = *), when it set to NA here.

ratio
(the value r, the ratio of two matrix traces.

lambda
the value of λ corresponding to spar, see the details above.

iparms
named integer(3) vector where ..$ipars["iter"] gives number of spar computing iterations used.

auxMat
experimental; when keep.stuff was true, a “flat” numeric vector containing parts of the internal computations.

fit
list for use by predict.smooth.spline, with components

knot: the knot sequence (including the repeated boundary knots), scaled into [0, 1] (via min and range).

nk: number of coefficients or number of ‘proper’ knots plus 2.

coef: coefficients for the spline basis used.

min, range: numbers giving the corresponding quantities of x.

call
the matched call.

method(class = "smooth.spline") shows a hatvalues() method based on the lev vector above.

Note
The number of unique x values, nx = nx, are determined by the tol argument, equivalently to

\[ nx \leftarrow \text{length}(x) - \sum(\text{duplicated}(\text{round}((x - \text{mean}(x)) / \text{tol})) ) \]

The default all.knots = FALSE and nknots = .nknots.smpl, entails using only \( O(n_x^{0.2}) \) knots instead of \( n_x \) for \( n_x > 49 \). This cuts speed and memory requirements, but not drastically anymore since \( R \) version 1.5.1 where it is only \( O(n_k) + O(n) \) where \( n_k \) is the number of knots.

In this case where not all unique x values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large df) is used.

Author(s)
R implementation by B. D. Ripley and Martin Maechler (spar/lambda, etc).

Source
This function is based on code in the GAMFIT Fortran program by T. Hastie and R. Tibshirani (originally taken from http://lib.stat.cmu.edu/general/gamfit) which makes use of spline code by Finbarr O’Sullivan. Its design parallels the smooth.spline function of Chambers & Hastie (1992).

Examples

```r
require(graphics)
plot(dist ~ speed, data = cars, main = "data(cars) & smoothing splines")
cars.spl <- with(cars, smooth.spline(speed, dist))
cars.spl
## This example has duplicate points, so avoid cv = TRUE

lines(cars.spl, col = "blue")
ss10 <- smooth.spline(cars[,"speed"], cars[,"dist"], df = 10)
lines(ss10, lty = 2, col = "red")
legend(5,120,c(paste("default \[C.V.\] => df =",round(cars.spl$df,1)),
   "s( * , df = 10)"), col = c("blue","red"), lty = 1:2,
   bg = 'bisque')

## Residual (Tukey Anscombe) plot:
plot(residuals(cars.spl) ~ fitted(cars.spl))
abline(h = 0, col = "gray")

## consistency check:
stopifnot(all.equal(cars$dist,
   fitted(cars.spl) + residuals(cars.spl)))

## The chosen inner knots in original x-scale :
with(cars.spl$fit, min + range * knot[-c(1:3, nk+1 +1:3)]) # == unique(cars$speed)

## Visualize the behavior of .nknots.smspl()

nKnots <- Vectorize(.nknots.smspl) ; c.. <- adjustcolor("gray20",.5)
curve(nKnots, 1, 250, n=250)
abline(0,1, lty=2, col=c..); text(90,90,"y = x", col=c.., adj=-.25)
abline(h=100,lty=2); abline(v=200, lty=2)

n <- c(1:799, seq(800, 3400, by=10), seq(3500, 10000, by = 50))
plot(n, nKnots(n), type="l", main = "Vectorize(.nknots.smspl) (n)"
abline(0,1, lty=2, col=c..); text(180,180,"y = x", col=c..)

n0 <- c(50, 200, 800, 3200); c0 <- adjustcolor("blue3", .5)
lines(n0, nKnots(n0), type="h", col=c0)
axis(1, at=n0, line=-2, col.ticks=c0, col=NA, col.axis=c0)
axis(4, at=.nknots.smspl(10000), line=-.5, col=c..,col.axis=c.., las=1)

##-- artificial example
y18 <- c(1:3, 5, 4, 7:3, 2*(2:5), rep(10, 4))
xx <- seq(1, length(y18), len = 201)
(s2 <- smooth.spline(y18)) # GCV
(s02 <- smooth.spline(y18, spar = 0.2))
(s02. <- smooth.spline(y18, spar = 0.2, cv = NA))
plot(y18, main = deparse(s2$call), col.main = 2)
lines(s2, col = "gray"); lines(predict(s2, xx), col = 2)
lines(predict(s02, xx), col = 3); mtext(deparse(s02$call), col = 3)

## Specifying 'lambda' instead of usual spar :
(s2. <- smooth.spline(y18, lambda = s2$lambda, tol = s2$tol))
```
## The following shows the problematic behavior of 'spar' searching:

```r
(s2 <- smooth.spline(y18, control =
    list(trace = TRUE, tol = 1e-6, low = -1.5)))
(s2m <- smooth.spline(y18, cv = TRUE, control =
    list(trace = TRUE, tol = 1e-6, low = -1.5)))
## both above do quite similarly (Df = 8.5 +- 0.2)
```

---

### smoothEnds

#### Description

Smooth end points of a vector `y` using subsequently smaller medians and Tukey’s end point rule at the very end. (of odd span),

#### Usage

```r
smoothEnds(y, k = 3)
```

#### Arguments

- `y`: dependent variable to be smoothed (vector).
- `k`: width of largest median window; must be odd.

#### Details

`smoothEnds` is used to only do the ‘end point smoothing’, i.e., change at most the observations closer to the beginning/end than half the window `k`. The first and last value are computed using *Tukey's end point rule*, i.e., `sm[1] = median(y[1], sm[2], 3*sm[2] - 2*sm[3])`.

#### Value

vector of smoothed values, the same length as `y`.

#### Author(s)

Martin Maechler

#### References

#### See Also

`runmed(*, endrule = "median")` which calls `smoothEnds()`.
Examples

```r
require(graphics)

y <- ys <- (-20:20)^2
y[c(1, 10, 21, 41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue", "blue", "steelblue")
plot(y, main = "Running Medians -- runmed(\(x, k=7, \) end.rule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7., s7m), lwd = 1.5, lty = 1, col = col3)
legend(1, 470, paste("endrule", c("keep", "constant", "median"), sep = " = "),
  col = col3, lwd = 1.5, lty = 1)
stopifnot(identical(s7m, smoothEnds(s7k, 7)))
```

---

sortedXyData  
Create a sortedXyData Object

Description

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the initial function for a self-starting nonlinear regression model, which will be of the selfStart class.

Usage

```r
sortedXyData(x, y, data)
```

Arguments

- `x`  
a numeric vector or an expression that will evaluate in `data` to a numeric vector
- `y`  
a numeric vector or an expression that will evaluate in `data` to a numeric vector
- `data`  
an optional data frame in which to evaluate expressions for `x` and `y`, if they are given as expressions

Value

A sortedXyData object. This is a data frame with exactly two numeric columns, named `x` and `y`. The rows are sorted so the `x` column is in increasing order. Duplicate `x` values are eliminated by averaging the corresponding `y` values.

Author(s)

José Pinheiro and Douglas Bates

- `NLSstRtAsymptote`
spec.ar

Examples

DNase.2 <- DNase[ DNase$Run == "2", ]
sortedXyData( expression(log(conc)), expression(density), DNase.2 )

Description

Fits an AR model to x (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

Usage

spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail, 
method = "yule-walker", ...)

Arguments

x A univariate (not yet: or multivariate) time series or the result of a fit by ar.
n.freq The number of points at which to plot.
order The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
plot Plot the periodogram?
na.action NA action function.
method method for ar fit.
... Graphical arguments passed to plot.spec.

Value

An object of class "spec". The result is returned invisibly if plot is true.

Warning

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

Note

The multivariate case is not yet implemented.

References

See Also

ar, spectrum.
Examples

```r
require(graphics)

spec.ar(lh)
spec.ar(ldeaths)
spec.ar(ldeaths, method = "burg")

spec.ar(log(lynx))
spec.ar(log(lynx), method = "burg", add = TRUE, col = "purple")
spec.ar(log(lynx), method = "mle", add = TRUE, col = "forest green")
spec.ar(log(lynx), method = "ols", add = TRUE, col = "blue")
```

**spec.pgram**

*Estimate Spectral Density of a Time Series by a Smoothed Periodogram*

**Description**

`spec.pgram` calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

**Usage**

```r
spec.pgram(x, spans = NULL, kernel, taper = 0.1, pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE, plot = TRUE, na.action = na.fail, ...)
```

**Arguments**

- `x`: univariate or multivariate time series.
- `spans`: vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.
- `kernel`: alternatively, a kernel smoother of class "tskernel".
- `taper`: specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.
- `pad`: proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion `pad`.
- `fast`: logical; if `TRUE`, pad the series to a highly composite length.
- `demean`: logical. If `TRUE`, subtract the mean of the series.
- `detrend`: logical. If `TRUE`, remove a linear trend from the series. This will also remove the mean.
- `plot`: plot the periodogram?
- `na.action`: NA action function.
- `...`: graphical arguments passed to `plot.spec`.
**Details**

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the `fast` and not the `pad` argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

**Value**

A list object of class "spec" (see `spectrum`) with the following additional components:

- `kernel`: The kernel argument, or the kernel constructed from `spans`.
- `df`: The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with `df` degrees of freedom.
- `bandwidth`: The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).
- `taper`: The value of the `taper` argument.
- `pad`: The value of the `pad` argument.
- `detrend`: The value of the `detrend` argument.
- `demean`: The value of the `demean` argument.

The result is returned invisibly if `plot` is true.

**Author(s)**

Originally Martyn Plummer; kernel smoothing by Adrian Trapletti, synthesis by B.D. Ripley

**References**

**See Also**

`spectrum, spec.taper, plot.spec, fft`

**Examples**

require(graphics)

## Examples from Venables & Ripley
spectrum(ldeaths)
spectrum(ldeaths, spans = c(3,5))
spectrum(ldeaths, spans = c(5,7))
spectrum(mdeaths, spans = c(3,3))
```
spec.taper

Taper a Time Series by a Cosine Bell

Description

Apply a cosine-bell taper to a time series.

Usage

spec.taper(x, p = 0.1)

Arguments

x A univariate or multivariate time series

p The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series.).

Details

The cosine-bell taper is applied to the first and last p[1] observations of time series x[, 1].

Value

A new time series object.

See Also

spec.pgram, cpgram
spectrum

Spectral Density Estimation

Description
The spectrum function estimates the spectral density of a time series.

Usage
spectrum(x, ..., method = c("pgram", "ar"))

Arguments
x A univariate or multivariate time series.
method String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar". Can be abbreviated.
... Further arguments to specific spec methods or plot.spec.

Details
spectrum is a wrapper function which calls the methods spec.pgram and spec.ar.
The spectrum here is defined with scaling \(1/frequency(x)\), following S-PLUS. This makes the spectral density a density over the range \((-frequency(x)/2, +frequency(x)/2]\), whereas a more common scaling is \(2\pi\) and range \((-0.5, 0.5]\) (e.g., Bloomfield) or 1 and range \((-\pi, \pi]\).

If available, a confidence interval will be plotted by plot.spec: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

Value
An object of class "spec", which is a list containing at least the following components:

freq vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see ‘Details’ below.
spec Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to freq.
coh NULL for univariate series. For multivariate time series, a matrix containing the squared coherency between different series. Column \(i + (j - 1) \times (j - 2)/2\) of coh contains the squared coherency between columns \(i\) and \(j\) of \(x\), where \(i < j\).
phase NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as coh.
series The name of the time series.
snames For multivariate input, the names of the component series.
method The method used to calculate the spectrum.

The result is returned invisibly if plot is true.
splinefun

Interpolating Splines

Description

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a function performing the interpolation.
splinefun

Usage

splinefun(x, y = NULL,
      method = c("fmm", "periodic", "natural", "monoH.FC", "hyman"),
      ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm",
      xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)

Arguments

x, y vectors giving the coordinates of the points to be interpolated. Alternatively a
single plotting structure can be specified: see xy.coords.
y must be increasing or decreasing for method = "hyman".

m (for splinefunH()): vector of slopes \( m_i \) at the points \( (x_i, y_i) \); these together
determine the Hermite “spline” which is piecewise cubic, (only) once differentiable continuously.

method specifies the type of spline to be used. Possible values are "fmm", "natural",
"periodic", "monoH.FC" and "hyman". Can be abbreviated.

n if xout is left unspecified, interpolation takes place at \( n \) equally spaced points
spanning the interval \([\text{xmin}, \text{xmax}]\).

xmin, xmax left-hand and right-hand endpoint of the interpolation interval (when xout is
unspecified).

xout an optional set of values specifying where interpolation is to take place.

ties handling of tied x values. Either a function with a single vector argument returning
a single number result or the string "ordered"; note that the latter is the fastest for large length(x).

Details

The inputs can contain missing values which are deleted, so at least one complete \((x, y)\) pair is
required. If method = "fmm", the spline used is that of Forsythe, Malcolm and Moler (an exact
cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when method = "natural", and periodic splines when method = "periodic".

The method "monoH.FC" computes a monotone Hermite spline according to the method of Fritsch
and Carlson. It does so by determining slopes such that the Hermite spline, determined by
\((x_i, y_i, m_i)\), is monotone (increasing or decreasing) iff the data are.

Method "hyman" computes a monotone cubic spline using Hyman filtering of an method = "fmm"
fit for strictly monotonic inputs.

These interpolation splines can also be used for extrapolation, that is prediction at points outside
the range of \(x\). Extrapolation makes little sense for method = "fmm"; for natural splines it is linear
using the slope of the interpolating curve at the nearest data point.

Value

spline returns a list containing components x and y which give the ordinates where interpolation
took place and the interpolated values.
splinefun returns a function with formal arguments `x` and `deriv`, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (`deriv = 0`), or its derivatives (`deriv = 1, 2, 3`) at the points `x`, where the spline function interpolates the data points originally specified. It uses data stored in its environment when it was created, the details of which are subject to change.

Warning

The value returned by `splinefun` contains references to the code in the current version of R; it is not intended to be saved and loaded into a different R session. This is safer in R >= 3.0.0.

Author(s)

R Core Team.

Simon Wood for the original code for Hyman filtering.

SSasymp

Self-Starting Nls Asymptotic Regression Model

Description

This selfStart model evaluates the asymptotic regression function and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, R0, and lrc for a given set of data.

Note that SSweibull() generalizes this asymptotic model with an extra parameter.

Usage

SSasymp(input, Asym, R0, lrc)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
R0 a numeric parameter representing the response when input is zero.
lrc a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as input. It is the value of the expression Asym+(R0-Asym)*exp(-exp(lrc)*input). If all of the arguments Asym, R0, and lrc are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSasympOff

Self-Starting Nls Asymptotic Regression Model with an Offset

Description

This selfStart model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an initial attribute that creates initial estimates of the parameters Asym, lrc, and c0.
Usage

SSasympOff(input, Asym, lrc, c0)

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the horizontal asymptote on the right side (very large values of input).
lrc a numeric parameter representing the natural logarithm of the rate constant.
c0 a numeric parameter representing the input for which the response is zero.

Value

a numeric vector of the same length as input. It is the value of the expression Asym*(1 - exp(-exp(lrc)*(input - c0))). If all of the arguments Asym, lrc, and c0 are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSasympOrig

Self-Starting Nls Asymptotic Regression Model through the Origin

Description

This `selfStart` model evaluates the asymptotic regression function through the origin and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters `Asym` and `lrc` for a given set of data.

Usage

`SSasympOrig(input, Asym, lrc)`

Arguments

- **input**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the horizontal asymptote.
- **lrc**: a numeric parameter representing the natural logarithm of the rate constant.

Value

A numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*input))`. If all of the arguments `Asym` and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp

Self-Starting Nls Biexponential model

Description

This selfStart model evaluates the biexponential model function and its gradient. It has an initial attribute that creates initial estimates of the parameters A1, lrc1, A2, and lrc2.

Usage

SSbiexp(input, A1, lrc1, A2, lrc2)
**SSbiexp**

**Arguments**

- **input**: a numeric vector of values at which to evaluate the model.
- **A1**: a numeric parameter representing the multiplier of the first exponential.
- **lrc1**: a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
- **A2**: a numeric parameter representing the multiplier of the second exponential.
- **lrc2**: a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

**Value**

A numeric vector of the same length as `input`. It is the value of the expression \( A1 \cdot \exp(-\exp(lrc1) \cdot \text{input}) + A2 \cdot \exp(-\exp(lrc2) \cdot \text{input}) \). If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

```
Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

Usage

```r
# S3 method for class 'mlm'
SSD(object, ...)  
# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)
```

Arguments

- `object`: object of class "mlm", or "SSD" in the case of `estVar`.
- `...`: Unused

Value

`SSD()` returns a list of class "SSD" containing the following components

- `SSD`: The residual sums of squares and products matrix
- `df`: Degrees of freedom
- `call`: Copied from `object`

`estVar` returns a matrix with the estimated variances and covariances.

\textbf{SSfol} \quad \textit{Self-Starting Nls First-order Compartment Model}

\textbf{Description}

This selfStart model evaluates the first-order compartment function and its gradient. It has an initial attribute that creates initial estimates of the parameters l\( \text{Ke} \), l\( \text{Ka} \), and l\( \text{Cl} \).

\textbf{Usage}

\texttt{SSfol(Dose, input, lKe, lKa, lCl)}

\textbf{Arguments}

- \texttt{Dose}: a numeric value representing the initial dose.
- \texttt{input}: a numeric vector at which to evaluate the model.
- \texttt{lKe}: a numeric parameter representing the natural logarithm of the elimination rate constant.
- \texttt{lKa}: a numeric parameter representing the natural logarithm of the absorption rate constant.
- \texttt{lCl}: a numeric parameter representing the natural logarithm of the clearance.

\textbf{Value}

a numeric vector of the same length as \texttt{input}, which is the value of the expression

\begin{equation}
\text{Dose} \times \exp(lKe+lKa-lCl) \times (\exp(-exp(lKe)*input) - \exp(-exp(lKa)*input)) / (\exp(lKa) - \exp(lKe))
\end{equation}

If all of the arguments l\( \text{Ke} \), l\( \text{Ka} \), and l\( \text{Cl} \) are names of objects, the gradient matrix with respect to these names is attached as an attribute named \texttt{gradient}.

**SSfpl**  
Self-Starting Nls Four-Parameter Logistic Model

**Description**

This *selfStart* model evaluates the four-parameter logistic function and its gradient. It has an initial attribute computing initial estimates of the parameters A, B, xmid, and scal for a given set of data.

**Usage**

`SSfpl(input, A, B, xmid, scal)`

**Arguments**

- `input` a numeric vector of values at which to evaluate the model.
- `A` a numeric parameter representing the horizontal asymptote on the left side (very small values of `input`).
- `B` a numeric parameter representing the horizontal asymptote on the right side (very large values of `input`).
- `xmid` a numeric parameter representing the input value at the inflection point of the curve. The value of `SSfpl` will be midway between `A` and `B` at `xmid`.
- `scal` a numeric scale parameter on the input axis.

**Value**

A numeric vector of the same length as `input`. It is the value of the expression `A+(B-A)/(1+exp((xmid-input)/scal))`. If all of the arguments `A`, `B`, `xmid`, and `scal` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSgompertz

Self-Starting Nls Gompertz Growth Model

Description

This selfStart model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters Asym, b2, and b3.

Usage

SSgompertz(x, Asym, b2, b3)
Arguments

- **x**: a numeric vector of values at which to evaluate the model.
- **Asym**: a numeric parameter representing the asymptote.
- **b2**: a numeric parameter related to the value of the function at \( x = 0 \)
- **b3**: a numeric parameter related to the scale the \( x \) axis.

Value

A numeric vector of the same length as \( input \). It is the value of the expression \( Asym \times \exp(-b2 \times b3^x) \). If all of the arguments \( Asym, b2, \) and \( b3 \) are names of objects the gradient matrix with respect to these names is attached as an attribute named \( gradient \).

```

**SSlogis**

**Self-Starting Nls Logistic Model**

**Description**

This selfStart model evaluates the logistic function and its gradient. It has an initial attribute that creates initial estimates of the parameters \( Asym, xmid, \) and \( scal \). In R 3.4.2 and earlier, that init function failed when \( \min(input) \) was exactly zero.

**Usage**

`SSlogis(input, Asym, xmid, scal)`
SSlogis

Arguments

input a numeric vector of values at which to evaluate the model.
Asym a numeric parameter representing the asymptote.
xmid a numeric parameter representing the x value at the inflection point of the curve.
The value of SSlogis will be Asym/2 at xmid.
scal a numeric scale parameter on the input axis.

Value

a numeric vector of the same length as input. It is the value of the expression
Asym/(1+exp((xmid-input)/scal)). If all of the arguments Asym, xmid, and scal are names of
objects the gradient matrix with respect to these names is attached as an attribute named gradient.

SSmicmen

Self-Starting Nls Michaelis-Menten Model

Description

This selfStart model evaluates the Michaelis-Menten model and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Vm and K.

Usage

SSmicmen(input, Vm, K)

Arguments

input  
a numeric vector of values at which to evaluate the model.

Vm  
a numeric parameter representing the maximum value of the response.

K  
a numeric parameter representing the input value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.

Value

a numeric vector of the same length as input. It is the value of the expression \( Vm \times input / (K + input) \). If both the arguments Vm and K are names of objects, the gradient matrix with respect to these names is attached as an attribute named gradient.

SSweibull

Self-Starting Nls Weibull Growth Curve Model

Description

This selfStart model evaluates the Weibull model for growth curve data and its gradient. It has an initial attribute that will evaluate initial estimates of the parameters Asym, Drop, lrc, and pwr for a given set of data.

Usage

```r
SSweibull(x, Asym, Drop, lrc, pwr)
```
Arguments

\texttt{x} \hspace{1cm} \text{a numeric vector of values at which to evaluate the model.}

\texttt{Asym} \hspace{1cm} \text{a numeric parameter representing the horizontal asymptote on the right side (very small values of x).}

\texttt{Drop} \hspace{1cm} \text{a numeric parameter representing the change from Asym to the y intercept.}

\texttt{lrc} \hspace{1cm} \text{a numeric parameter representing the natural logarithm of the rate constant.}

\texttt{pwr} \hspace{1cm} \text{a numeric parameter representing the power to which x is raised.}

Details

This model is a generalization of the \texttt{SSasymp} model in that it reduces to \texttt{SSasymp} when \texttt{pwr} is unity.

Value

\text{a numeric vector of the same length as \texttt{x}. It is the value of the expression Asym-Drop*exp(-exp(lrc)*x^pwr).}\n
If all of the arguments Asym, Drop, lrc, and pwr are names of objects, the gradient matrix with respect to these names is attached as an attribute named \texttt{gradient}.

Author(s)

Douglas Bates

\end{verbatim}
**start**  
*Encode the Terminal Times of Time Series*

**Description**

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

**Usage**

```r
start(x, ...)  
end(x, ...)
```

**Arguments**

- `x` a univariate or multivariate time-series, or a vector or matrix.
- `...` extra arguments for future methods.

**Details**

These are generic functions, which will use the `tsp` attribute of `x` if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency `f`, time `n+i/f` is presented as `c(n, i+1)` (even for `i = 0` and `f = 1`).

**Warning**

The representation used by `start` and `end` has no meaning unless the frequency is supplied.

**See Also**

`ts`, `time`, `tsp`.

---

**stat.anova**  
*GLM Anova Statistics*

**Description**

This is a utility function, used in `lm` and `glm` methods for `anova(..., test != NULL)` and should not be used by the average user.

**Usage**

```r
stat.anova(table, test = c("Rao", "LRT", "Chisq", "F", "Cp"),  
           scale, df.scale, n)
```
Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>table</code></td>
<td>numeric matrix as results from <code>anova.glm(..., test = NULL)</code>.</td>
</tr>
<tr>
<td><code>test</code></td>
<td>a character string, partially matching one of &quot;Rao&quot;, &quot;LRT&quot;, &quot;Chisq&quot;, &quot;F&quot; or &quot;Cp&quot;.</td>
</tr>
<tr>
<td><code>scale</code></td>
<td>a residual mean square or other scale estimate to be used as the denominator in an F test.</td>
</tr>
<tr>
<td><code>df.scale</code></td>
<td>degrees of freedom corresponding to <code>scale</code>.</td>
</tr>
<tr>
<td><code>n</code></td>
<td>number of observations.</td>
</tr>
</tbody>
</table>

Value

A matrix which is the original `table`, augmented by a column of test statistics, depending on the `test` argument.

References

See Also

`anova.lm`, `anova.glm`.

Examples

```r
###-- Continued from '?glm':

print(ag <- anova(glm.D93))
stat.anova(ag$table, test = "Cp",
  scale = sum(resid(glm.D93, "pearson")^2)/4,
  df.scale = 4, n = 9)
```

stats-deprecated

**Deprecated Functions in Package stats**

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

Usage

```r
plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0, square = TRUE, labels = NULL, plot. = TRUE,
  axes = TRUE, frame.plot = FALSE, ann = TRUE,
  main = "", sub = NULL, xlab = NULL, ylab = "Height")
```
Arguments

- **tree**: an object of the type produced by `hclust`.
- **hang**: The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
- **unit**: logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.
- **labels**: A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If `labels = FALSE` no labels at all are plotted.
- **axes, frame.plot, ann**: logical flags as in `plot.default`.
- **main, sub, xlab, ylab**: character strings for `title`. `sub` and `xlab` have a non-NULL default when there’s a `tree$call`.
- **...**: Further graphical arguments. E.g., `cex` controls the size of the labels (if plotted) in the same way as `text`.
- **hmin**: numeric. All heights less than `hmin` are regarded as being `hmin`: this can be used to suppress detail at the bottom of the tree.
- **level, square, plot**: unimplemented arguments for S-PLUS compatibility.

Details

`plcust` is a deprecated wrapper for the `plot` method for `hclust`, provided long ago for S-PLUS compatibility.

- **Deprecated**

---

**step**

*Choose a model by AIC in a Stepwise Algorithm*

**Description**

Select a formula-based model by AIC.

**Usage**

```r
step(object, scope, scale = 0,
    direction = c("both", "backward", "forward"),
    trace = 1, keep = NULL, steps = 1000, k = 2, ...)```
Arguments

object  
an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.

scope  
defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components `upper` and `lower`, both formulae. See the details for how to specify the formulae and how they are used.

scale  
used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. The default value, 0, indicates the scale should be estimated: see `extractAIC`.

direction  
the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the scope argument is missing the default for `direction` is "backward". Values can be abbreviated.

trace  
if positive, information is printed during the running of `step`. Larger values may give more detailed information.

keep  
a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically `keep` will select a subset of the components of the object and return them. The default is not to keep anything.

steps  
the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.

k  
the multiple of the number of degrees of freedom used for the penalty. Only k = 2 gives the genuine AIC: k = log(n) is sometimes referred to as BIC or SBC.

...  
any additional arguments to `extractAIC`.

Details

`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows’ $C_p$, this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the `lower` model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`. So using . in a `scope` formula means 'what is already there', with .^2 indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).
Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package MASS for a wider range of object classes.

Author(s)

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package MASS (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

```
stepfun

Step Functions - Creation and Class

Description

Given the vectors \((x_1, \ldots, x_n)\) and \((y_0, y_1, \ldots, y_n)\) (one value more!), `stepfun(x, y, ...)` returns an interpolating 'step' function, say \(fn\). I.e., \(fn(t) = c_i\) (constant) for \(t \in (x_i, x_{i+1})\) and at the abscissa values, if (by default) \(right = \text{FALSE}\), \(fn(x_i) = y_i\) and for \(right = \text{TRUE}\), \(fn(x_i) = y_{i-1}\) for \(i = 1, \ldots, n\).

The value of the constant \(c_i\) above depends on the 'continuity' parameter \(f\). For the default, \(right = \text{FALSE}, f = 0\), \(fn\) is a \textit{cadlag} function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their left endpoint. In general, \(c_i\) is interpolated in between the neighbouring \(y\) values, \(c_i = (1 - f)y_i + f \cdot y_{i+1}\). Therefore, for non-0 values of \(f\), \(fn\) may no longer be a proper step function, since it can be discontinuous from both sides, unless \(right = \text{TRUE}, f = 1\) which is left-continuous (i.e., constant pieces contain their right endpoint).

Usage

```
stepfun(x, y, f = as.numeric(right), ties = "ordered",
        right = FALSE)
```

is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)

## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'stepfun'
summary(object, ...)

Arguments

- **x**: numeric vector giving the knots or jump locations of the step function for `stepfun()`. For the other functions, \(x\) is as `object` below.
- **y**: numeric vector one longer than \(x\), giving the heights of the function values between the \(x\) values.
- **f**: a number between 0 and 1, indicating how interpolation outside the given \(x\) values should happen. See `approxfun`.
- **ties**: Handling of tied \(x\) values. Either a function or the string "ordered". See `approxfun`.
- **right**: logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
- **Fn, object**: an \(R\) object inheriting from "stepfun".
- **digits**: number of significant digits to use, see `print`.
- **...**: potentially further arguments (required by the generic).
Value

A function of class "stepfun", say \texttt{fn}.

There are methods available for summarizing ("summary(.)"), representing ("print(.)") and plotting ("plot(.)", see \texttt{plot.stepfun}) "stepfun" objects.

The \texttt{environment} of \texttt{fn} contains all the information needed;

"x","y" the original arguments

"n" number of knots (x values)

"f" continuity parameter

"yleft", "yright" the function values outside the knots

"method" (always = "constant", from \texttt{approxfun(.)}).

The knots are also available via \texttt{knots(fn)}.

Note

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of \texttt{R} (and did at \texttt{R} 3.0.0). They can usually be re-created by

\begin{verbatim}
  eval(attr(old_obj, "call"), environment(old_obj))
\end{verbatim}

since the data used is stored as part of the object’s environment.

y0 <- c(1., 2., 4., 3.)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = 0.2)
sfun1 <- stepfun(1:3, y0, f = 1)
sfun1c <- stepfun(1:3, y0, right = TRUE) # hence f=1
sfun0
summary(sfun0)
summary(sfun.2)

## look at the internal structure:
unclass(sfun0)
ls(envir = environment(sfun0))

x0 <- seq(0.5, 3.5, by = 0.25)
rbind(x = x0, f.f0 = sfun0(x0), f.f02 = sfun.2(x0),
     f.f1 = sfun1(x0), f.f1c = sfun1c(x0))

## Identities :
stopifnot(identical(y0[-1], sfun0(1:3)), # right = FALSE
          identical(y0[-4], sfun1c(1:3))) # right = TRUE
\end{verbatim}
Seasonal Decomposition of Time Series by Loess

Description

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.

Usage

```r
stl(x, s.window, s.degree = 0,
t.window = NULL, t.degree = 1,
l.window = nextodd(period), l.degree = t.degree,
s.jump = ceiling(s.window/10),
t.jump = ceiling(t.window/10),
l.jump = ceiling(l.window/10),
robust = FALSE,
inner = if(robust) 1 else 2,
outer = if(robust) 15 else 0,
na.action = na.fail)
```

Arguments

- **x**: univariate time series to be decomposed. This should be an object of class “ts” with a frequency greater than one.
- **s.window**: either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd and at least 7, according to Cleveland et al. This has no default.
- **s.degree**: degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.
- **t.window**: the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, `nextodd(ceiling((1.5*period) / (1-(1.5/s.window))))`, is taken.
- **t.degree**: degree of locally-fitted polynomial in trend extraction. Should be zero or one.
- **l.window**: the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to `frequency(x)` which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one.
- **l.degree**: degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.
- **s.jump**, **t.jump**, **l.jump**: integers at least one to increase speed of the respective smoother. Linear interpolation happens between every *jump*th value.
- **robust**: logical indicating if robust fitting be used in the loess procedure.
- **inner**: integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iterations suffice.
- **outer**: integer; the number of ‘outer’ robustness iterations.
- **na.action**: action on missing values.
Details

The seasonal component is found by loess smoothing the seasonal sub-series (the series of all January values, ...); if s.window = "periodic" smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The remainder component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, plot.stl.

Value

stl returns an object of class "stl" with components

time.series a multiple time series with columns seasonal, trend and remainder.
weights the final robust weights (all one if fitting is not done robustly).
call the matched call.
win integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.
deg integer (length 3 vector) with the polynomial degrees for these smoothers.
jump integer (length 3 vector) with the 'jumps' (skips) used for these smoothers.
ini number of inner iterations
no number of outer robustness iterations

Note

This is similar to but not identical to the stl function in S-PLUS. The remainder component given by S-PLUS is the sum of the trend and remainder series from this function.

plot(stmd, set.pars = NULL, labels = NULL,
     main = "stl(mdeaths, s.w = "per", robust = FALSE / TRUE )")
plot(stmR, set.pars = NULL)
# mark the 'outliers':
(iO <- which(stmR$weights < 1e-8))  # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[iO], 0.8* sts[,"remainder"][iO], pch = 4, col = "red")
par(op)  # reset
```

---

### stlmethods

**Methods for STL Objects**

**Description**

Methods for objects of class `stl`, typically the result of `stl`. The plot method does a multiple figure plot with some flexibility.

There are also (non-visible) `print` and `summary` methods.

**Usage**

```r
## S3 method for class 'stl'
plot(x, labels = colnames(X),
     set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                    tck = -0.01, mfrow = c(nplot, 1)),
     main = NULL, range.bars = TRUE, ...
     col.range = "light gray")
```

**Arguments**

- `x` **stl** object.
- `labels` character of length 4 giving the names of the component time-series.
- `set.pars` settings for `par(.)` when setting up the plot.
- `main` plot main title.
- `range.bars` logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.
- `...` further arguments passed to or from other methods.
- `col.range` colour to be used for the range bars, if plotted. Note this appears after `...` and so cannot be abbreviated.

**See Also**

`plot.ts` and `stl`, particularly for examples.
StructTS Fit Structural Time Series

Description

Fit a structural model for a time series by maximum likelihood.

Usage

StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
fixed = NULL, optim.control = NULL)

Arguments

x a univariate numeric time series. Missing values are allowed.
type the class of structural model. If omitted, a BSM is used for a time series with frequency(x) > 1, and a local trend model otherwise. Can be abbreviated.
init initial values of the variance parameters.
fixed optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in fixed will be varied. Probably most useful for setting variances to zero.
optim.control List of control parameters for optim. Method "L-BFGS-B" is used.

Details

Structural time series models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the local level model specified by type = "level". This has an underlying level $\mu_t$ which evolves by

$$
\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
$$

The observations are

$$
x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
$$

There are two parameters, $\sigma_\xi^2$ and $\sigma_\epsilon^2$. It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The local linear trend model, type = "trend", has the same measurement equation, but with a time-varying slope in the dynamics for $\mu_t$, given by

$$
\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)
$$

$$
\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)
$$

with three variance parameters. It is not uncommon to find $\sigma_\zeta^2 = 0$ (which reduces to the local level model) or $\sigma_\xi^2 = 0$, which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The basic structural model, type = "BSM", is a local trend model with an additional seasonal component. Thus the measurement equation is

$$
x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)
$$
where $\gamma_t$ is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \cdots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma^2_\omega)$$

The boundary case $\sigma^2_\omega = 0$ corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

**Value**

A list of class "StructTS" with components:

- **coef**: the estimated variances of the components.
- **loglik**: the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to arima nor different types of structural models.
- **loglik0**: the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.
- **data**: the time series $x$.
- **residuals**: the standardized residuals.
- **fitted**: a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).
- **call**: the matched call.
- **series**: the name of the series $x$.
- **code**: the convergence code returned by optim.
- **model, model0**: Lists representing the Kalman Filter used in the fitting. See KalmanLike. model0 is the initial state of the filter, model its final state.
- **xtsp**: the tsp attributes of $x$.

**Note**

Optimization of structural models is a lot harder than many of the references admit. For example, the AirPassengers data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by StructTS. It is quite common to find fits with one or more variances zero, and this can include $\sigma^2_\epsilon$.

summary.aov

---

Summarize an Analysis of Variance Model

Description

Summarize an analysis of variance model.

Usage

## S3 method for class 'aov'
summary(object, intercept = FALSE, split,
         expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)

Arguments

object An object of class "aov" or "aovlist".
intercept logical: should intercept terms be included?
split an optional named list, with names corresponding to terms in the model. Each
       component is itself a list with integer components giving contrasts whose con-
       tributions are to be summed.
expand.split logical: should the split apply also to interactions involving the factor?
keep.zero.df logical: should terms with no degrees of freedom be included?
... Arguments to be passed to or from other methods, for summary.aovlist in-
       cluding those for summary.aov.
Value

An object of class c("summary.aov", "listof") or "summary.aovlist" respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class "anova" inheriting from class "data.frame". They have columns "Df", "Sum Sq", "Mean Sq", as well as "F value" and "Pr(>F)" if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for "Residuals" if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

Note

The use of expand.split = TRUE is little tested: it is always possible to set it to FALSE and specify exactly all the splits required.

Examples

### For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
  y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
  P = ordered(gl(3, 3)), N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
  P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)), expand.split = FALSE)
Usage

## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3),
symbolic.cor = x$symbolic.cor,
signif.stars = getOption("show.signif.stars"), ...)

Arguments

object an object of class "glm", usually, a result of a call to glm.

x an object of class "summary.glm", usually, a result of a call to summary.glm.

dispersion the dispersion parameter for the family used. Either a single numerical value or NULL (the default), when it is inferred from object (see 'Details').

correlation logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.

digits the number of significant digits to use when printing.

symbolic.cor logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.

signif.stars logical. If TRUE, 'significance stars' are printed for each coefficient.

... further arguments passed to or from other methods.

Details

print.summary.glm tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if signif.stars is TRUE. The coefficients component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled t ratio if the dispersion is estimated, and z ratio if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the t or z ratio based on a Student t or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the print method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If dispersion is not supplied or NULL, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

summary can be used with Gaussian glm fits to handle the case of a linear regression with known error variance, something not handled by summary.lm.

Value

summary.glm returns an object of class "summary.glm", a list with components

call the component from object.
family the component from object.
deviance the component from object.
contrasts the component from object.
df.residual the component from object.
null.deviance the component from object.
df.null the component from object.
deviance.resid the deviance residuals: see residuals.glm.
coefficients the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.
aliased named logical vector showing if the original coefficients are aliased.
dispersion either the supplied argument or the inferred/estimated dispersion if the latter is NULL.
df a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones).
cov.unscaled the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.
cov.scaled ditto, scaled by dispersion.
correlation (only if correlation is true.) The estimated correlations of the estimated coefficients.
symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

```
summary.lm

Summary of linear models

Description

summary method for class "lm".

Usage

### S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

### S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
Arguments

object
x
correlation
digits
symbolic.cor
signif.stars
...

Arguments:
object: an object of class "lm", usually, a result of a call to lm.
x: an object of class "summary.lm", usually, a result of a call to summary.lm.
correlation: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits: the number of significant digits to use when printing.
symbolic.cor: logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
signif.stars: logical. If TRUE, ‘significance stars’ are printed for each coefficient.
...: further arguments passed to or from other methods.

Details

print.summary.lm tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if signif.stars is TRUE.

Aliased coefficients are omitted in the returned object but restored by the print method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print summary(object)$correlation directly.

Value

The function summary.lm computes and returns a list of summary statistics of the fitted linear model given in object, using the components (list elements) "call" and "terms" from its argument, plus

residuals: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to lm.
coefficients: a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, $t$-statistic and corresponding (two-sided) $p$-value. Aliased coefficients are omitted.
aliased: named logical vector showing if the original coefficients are aliased.
sigma: the square root of the estimated variance of the random error
\[
\sigma^2 = \frac{1}{n - p} \sum_i w_i R_i^2,
\]
where $R_i$ is the $i$-th residual, residuals[i].
df: degrees of freedom, a 3-vector ($p, n - p, p^*$), the first being the number of non-aliased coefficients, the last being the total number of coefficients.
fstatistic: (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.
r.squared: $R^2$, the ‘fraction of variance explained by the model’,
\[
R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i(y_i - \bar{y})^2},
\]
where $\bar{y}$ is the mean of $y_i$ if there is an intercept and zero otherwise.
adj.r.squared: the above $R^2$ statistic ‘adjusted’, penalizing for higher $p$.
cov.unscaled: a $p \times p$ matrix of (unscaled) covariances of the $\hat{\beta}_j, j = 1, \ldots, p$.
correlation: the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified.
symbolic.cor: (only if correlation is true.) The value of the argument symbolic.cor.
na.action: from object, if present there.
See Also

The model fitting function \texttt{lm}, \texttt{summary}.

Function \texttt{coef} will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```r
##-- Continuing the \texttt{lm(.)} example:
coef(lm.D90) # the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
coef(sld90) # much more

## model with *aliased* coefficient:
lm.D9. <- lm(weight ~ group + I(group != "Ctl"))
Sm.D9. <- summary(lm.D9.)
Sm.D9. # shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D9.)) == 3, is.na(cc[3]),
dim(coef(Sm.D9.)) == c(2,4), Sm.D9.$df == c(2, 18, 3))
```

### Summary Method for Multivariate Analysis of Variance

**Description**

A summary method for class "manova".

**Usage**

```r
## S3 method for class 'manova'
summary(object, test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"), intercept = FALSE, tol = 1e-7, ...) 
```

**Arguments**

- **object**: An object of class "manova" or an \texttt{aov} object with multiple responses.
- **test**: The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
- **intercept**: logical. If TRUE, the intercept term is included in the table.
- **tol**: tolerance to be used in deciding if the residuals are rank-deficient: see \texttt{qr}.
- **...**: further arguments passed to or from other methods.

**Details**

The \texttt{summary.manova} method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and
Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

**Value**

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

- `row.names`: The names of the terms, the row names of the `stats` table if present.
- `SS`: A named list of sums of squares and product matrices.
- `Eigenvalues`: A matrix of eigenvalues.
- `stats`: A matrix of the statistics, approximate F value, degrees of freedom and P value.

otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).

**References**

**See Also**

**Examples**

```r
# Example on producing plastic film from Krzanowski (1998, p. 381)
tear <- c(6.5, 6.2, 5.8, 6.5, 6.5, 6.9, 7.2, 6.9, 6.1, 6.3,
          6.7, 6.6, 7.2, 7.1, 6.8, 7.1, 7.0, 7.2, 7.5, 7.6)
gloss <- c(9.5, 9.9, 9.6, 9.6, 9.2, 9.1, 10.0, 9.9, 9.5, 9.4,
          9.1, 9.3, 8.3, 8.4, 8.5, 9.2, 8.8, 9.7, 10.1, 9.2)
opacity <- c(4.4, 6.4, 3.0, 4.1, 0.8, 5.7, 2.0, 3.9, 1.9, 5.7,
            2.8, 4.1, 3.8, 1.6, 3.4, 8.4, 5.2, 6.9, 2.7, 1.9)
Y <- cbind(tear, gloss, opacity)
rate <- gl(2,10, labels = c("Low", "High"))
additive <- gl(2, 5, length = 20, labels = c("Low", "High"))

fit <- manova(Y ~ rate * additive)
summary.aov(fit) # univariate ANOVA tables
summary(fit, test = "Wilks") # ANOVA table of Wilks' lambda
summary(fit) # same F statistics as single-df terms
```
summarizing Non-Linear Least-Squares Model Fits

**Description**

summary method for class "nls".

**Usage**

```r
## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)
## S3 method for class 'summary.nls'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

- **object**: an object of class "nls".
- **x**: an object of class "summary.nls", usually the result of a call to `summary.nls`.
- **correlation**: logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
- **digits**: the number of significant digits to use when printing.
- **symbolic.cor**: logical. If TRUE, print the correlations in a symbolic form (see `symnum`) rather than as numbers.
- **signif.stars**: logical. If TRUE, 'significance stars' are printed for each coefficient.
- **...**: further arguments passed to or from other methods.

**Details**

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

`print.summary.nls` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

**Value**

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component "formula" from its argument, plus

- **residuals**: the weighted residuals, the usual residuals rescaled by the square root of the weights specified in the call to `nls`.
- **coefficients**: a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
sigma the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n - p} \sum_i R_i^2,$$

where $R_i$ is the $i$-th weighted residual.

df degrees of freedom, a 2-vector $(p, n - p)$. (Here and elsewhere $n$ omits observations with zero weights.)

cov.unscaled a $p \times p$ matrix of (unscaled) covariances of the parameter estimates.

correlation the correlation matrix corresponding to the above cov.unscaled, if correlation = TRUE is specified and there are a non-zero number of residual degrees of freedom.

symbolic.cor (only if correlation is true.) The value of the argument symbolic.cor.

See Also
The model fitting function nls, summary.

Function coef will extract the matrix of coefficients with standard errors, t-statistics and p-values.

---

**summary.princomp**

*Summary method for Principal Components Analysis*

**Description**

The summary method for class "princomp".

**Usage**

```r
## S3 method for class 'princomp'
summary(object, loadings = FALSE, cutoff = 0.1, ...)  
## S3 method for class 'summary.princomp'
print(x, digits = 3, loadings = x$print.loadings,  
      cutoff = x$cutoff, ...)
```

**Arguments**

- `object` an object of class "princomp", as from princomp().
- `loadings` logical. Should loadings be included?
- `cutoff` numeric. Loadings below this cutoff in absolute value are shown as blank in the output.
- `x` an object of class "summary.princomp".
- `digits` the number of significant digits to be used in listing loadings.
- `...` arguments to be passed to or from other methods.

**Value**

object with additional components cutoff and print.loadings.
See Also
princomp

Examples

summary(pc.cr <- princomp(USArrests, cor = TRUE))
## The signs of the loading columns are arbitrary
print(summary(princomp(USArrests, cor = TRUE),
loadings = TRUE, cutoff = 0.2), digits = 2)

supsmu

Friedman’s SuperSmoother

Description
Smooth the (x, y) values by Friedman’s ‘super smoother’.

Usage

supsmu(x, y, wt =, span = "cv", periodic = FALSE, bass = 0, trace = FALSE)

Arguments

x x values for smoothing
y y values for smoothing
wt case weights, by default all equal
span the fraction of the observations in the span of the running lines smoother, or “cv” to choose this by leave-one-out cross-validation.
periodic if TRUE, the x values are assumed to be in [0, 1] and of period 1.
bass controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.
trace logical, if true, prints one line of info “per spar”, notably useful for "cv".

Details

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with k/2 data points each side of the predicted point, and values of k as 0.5 × n, 0.2 × n and 0.05 × n, where n is the number of data points. If span is specified, a single smoother with span span × n is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples (n < 40) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother (span > 0) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of x, y or wt are dropped, with a warning.
Value

A list with components

x the input values in increasing order with duplicates removed.
y the corresponding y values on the fitted curve.

References

See Also

ppr

Examples

require(graphics)

with(cars, {
  plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})

Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
    symbols = if(numeric.x) c(" ", ".", ",", "+", "*", "B")
    else c(" ", ",", "|
    legend = length(symbols) >= 3,
    na = "?", eps = 1e-5, numeric.x = is.numeric(x),
    corr = missing(cutpoints) && numeric.x,
    show.max = if(corr) "1", show.min = NULL,
    abbr.colnames = has.colnames,
    lower.triangular = corr && is.numeric(x) && is.matrix(x),
    diag.lower.tri = corr && !is.null(show.max))
Arguments

- **x**: numeric or logical vector or array.
- **cutpoints**: numeric vector whose values cutpoints[j] = c_j (after augmentation, see corr below) are used for intervals.
- **symbols**: character vector, one shorter than (the augmented, see corr below) cutpoints. symbols[j] = s_j are used as 'code' for the (half open) interval (c_j, c_{j+1}]. When numeric.x is FALSE, i.e., by default when argument x is logical, the default is c(".", ") (graphical 0 / 1 s).
- **legend**: logical indicating if a "legend" attribute is desired.
- **na**: character or logical. How NAs are coded. If na == FALSE, NAs are coded invisibly, including the "legend" attribute below, which otherwise mentions NA coding.
- **eps**: absolute precision to be used at left and right boundary.
- **numeric.x**: logical indicating if x should be treated as numbers, otherwise as logical.
- **corr**: logical. If TRUE, x contains correlations. The cutpoints are augmented by 0 and 1 and abs(x) is coded.
- **show.max**: if TRUE, or of mode character, the maximal cutpoint is coded especially.
- **show.min**: if TRUE, or of mode character, the minimal cutpoint is coded especially.
- **abbr.colnames**: logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and x has no column names), the column names will all be empty, i.e., ""; otherwise if abbr.colnames is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to abbreviate(*, minlength = abbr.colnames).
- **lower.triangular**: logical. If TRUE and x is a matrix, only the lower triangular part of the matrix is coded as non-blank.
- **diag.lower.tri**: logical. If lower.triangular and this are TRUE, the diagonal part of the matrix is shown.

Value

An atomic character object of class noquote and the same dimensions as x.

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

\[ c_1 \text{s}_1 c_2 \text{s}_2 \ldots s_n c_{n+1} \]

where \( c_j = \text{cutpoints}[j] \) and \( s_j = \text{symbols}[j] \).

Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

## NA's:
Cm <- cor(matrix(rnorm(60), 10, 6)); Cm[,2] <- NA
symnum(Cm, show.max = NULL)
```

```r
## Graphical P-values (aka "significance stars"):
pval <- rev(sort(c(outer(1:6, 10^-(1:3)))))
sym <- symnum(pval, corr = FALSE,
cutpoints = c(0, .001,.01,.05, .1, 1),
symbols = c("***","**","*",".", " "))
noquote(cbind(P.val = format(pval), Signif = sym))
```

---

**t.test**  
**Student’s t-Test**

### Description

Performs one and two sample t-tests on vectors of data.

### Usage

```r
t.test(x, 
```

```r
## Default S3 method:
t.test(x, y = NULL,
```

---

**See Also**

*as.character; image*
alternative = c("two.sided", "less", "greater"),
mu = 0, paired = FALSE, var.equal = FALSE,
conf.level = 0.95, ...)

## S3 method for class 'formula'
t.test(formula, data, subset, na.action, ...)

Arguments

x 
  a (non-empty) numeric vector of data values.

y 
  an optional (non-empty) numeric vector of data values.

alternative 
  a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

mu 
  a number indicating the true value of the mean (or difference in means if you are performing a two sample test).

paired 
  a logical indicating whether you want a paired t-test.

var.equal 
  a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.

conf.level 
  confidence level of the interval.

formula 
  a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.

data 
  an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset 
  an optional vector specifying a subset of observations to be used.

na.action 
  a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").

... 
  further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

alternative = "greater" is the alternative that x has a larger mean than y.

If paired is TRUE then both x and y must be specified and they must be the same length. Missing values are silently removed (in pairs if paired is TRUE). If var.equal is TRUE then the pooled estimate of the variance is used. By default, if var.equal is FALSE then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

Value

A list with class "htest" containing the following components:

statistic 
  the value of the t-statistic.

parameter 
  the degrees of freedom for the t-statistic.

p.value 
  the p-value for the test.
The Student t Distribution

Density, distribution function, quantile function and random generation for the t distribution with df degrees of freedom (and optional non-centrality parameter ncp).

Usage

\[
\begin{align*}
\text{dt}(x, df, ncp, \log = \text{FALSE}) \\
\text{pt}(q, df, ncp, \text{lower.tail = TRUE, log.p = FALSE}) \\
\text{qt}(p, df, ncp, \text{lower.tail = TRUE, log.p = FALSE}) \\
\text{rt}(n, df, ncp)
\end{align*}
\]

Arguments

- \(x, q\) vector of quantiles.
- \(p\) vector of probabilities.
- \(n\) number of observations. If \(\text{length}(n) > 1\), the length is taken to be the number required.
- \(df\) degrees of freedom (> 0, maybe non-integer). \(df = \text{Inf}\) is allowed.
ncp  non-centrality parameter \( \delta \); currently except for \( \text{rt()} \), only for \( \text{abs(ncp)} \leq 37.62 \). If omitted, use the central t distribution.

log, log.p  logical; if TRUE, probabilities p are given as \( \log(p) \).

lower.tail  logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).

Details

The \( t \) distribution with \( df = \nu \) degrees of freedom has density

\[
f(x) = \frac{\Gamma((\nu+1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)} (1 + x^2/\nu)^{-(\nu+1)/2}
\]

for all real \( x \). It has mean 0 (for \( \nu > 1 \)) and variance \( \nu/(\nu-2) \) (for \( \nu > 2 \)).

The general non-central \( t \) with parameters \((\nu, \delta) = (df, ncp)\) is defined as the distribution of \( T_{\nu}(\delta) := (U + \delta)/\sqrt{V/\nu} \) where \( U \) and \( V \) are independent random variables, \( U \sim N(0,1) \) and \( V \sim \chi^2_\nu \) (see Chisquare).

The most used applications are power calculations for \( t \)-tests:

Let \( T = \frac{\overline{X} - \mu_0}{S/\sqrt{n}} \) where \( \overline{X} \) is the mean and \( S \) the sample standard deviation (sd) of \( X_1, X_2, \ldots, X_n \) which are i.i.d. \( N(\mu, \sigma^2) \). Then \( T \) is distributed as non-central \( t \) with \( df = n - 1 \) degrees of freedom and non-centrality parameter \( ncp = (\mu - \mu_0)\sqrt{n}/\sigma \).

Value

dt gives the density, pt gives the distribution function, qt gives the quantile function, and rt generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rt, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

Supplying \( ncp = 0 \) uses the algorithm for the non-central distribution, which is not the same algorithm used if \( ncp \) is omitted. This is to give consistent behaviour in extreme cases with values of \( ncp \) very near zero.

The code for non-zero \( ncp \) is principally intended to be used for moderate values of \( ncp \): it will not be highly accurate, especially in the tails, for large values.

Source

The central dt is computed via an accurate formula provided by Catherine Loader (see the reference in dbinom).

For the non-central case of dt, C code contributed by Claus Ekstrøm based on the relationship (for \( x \neq 0 \)) to the cumulative distribution.

For the central case of pt, a normal approximation in the tails, otherwise via pbeta.

For the non-central case of pt based on a C translation of

This computes the lower tail only, so the upper tail suffers from cancellation and a warning will be given when this is likely to be significant.

For central qt, a C translation of

altered to take account of

The non-central case is done by inversion.

Examples

```r
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10, 20, 50, 100, 1000))

tt <- seq(0, 10, len = 21)
cp <- seq(0, 6, len = 31)
ptn <- outer(tt, cp, function(t, d) pt(t, df = 3, ncp = d))
t.tit <- "Non-central t - Probabilities"
image(tt, cp, ptn, zlim = c(0, 1), main = t.tit)
persp(tt, cp, ptn, zlim = 0:1, r = 2, phi = 20, theta = 200, main = t.tit,
xlab = "t", ylab = "non-centrality parameter",
zb = "Pr(T <= t)"

plot(function(x) dt(x, df = 3, ncp = 2), -3, 11, ylim = c(0, 0.32),
main = "Non-central t - Density", yaxs = "i")
```

**termplot**

Plot Regression Terms

Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.
termplot

Usage

```r
termplot(model, data = NULL, envir = environment(formula(model)),
  partial.resid = FALSE, rug = FALSE,
  terms = NULL, se = FALSE,
  xlabs = NULL, ylabs = NULL, main = NULL,
  col.term = 2, lwd.term = 1.5,
  col.se = "orange", lty.se = 2, lwd.se = 1,
  col.res = "gray", cex = 1, pch = par("pch"),
  col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
  ask = dev.interactive() && nb.fig < n.tms,
  use.factor.levels = TRUE, smooth = NULL, ylim = "common",
  plot = TRUE, transform.x = FALSE, ...)
```

Arguments

- `model`: fitted model object
- `data`: data frame in which variables in `model` can be found
- `envir`: environment in which variables in `model` can be found
- `partial.resid`: logical; should partial residuals be plotted?
- `rug`: add rugplots (jittered 1-d histograms) to the axes?
- `terms`: which terms to plot (default NULL means all terms); a vector passed to `predict(.., type = "terms", terms = *)`.
- `se`: plot pointwise standard errors?
- `xlabs`: vector of labels for the x axes
- `ylabs`: vector of labels for the y axes
- `main`: logical, or vector of main titles; if TRUE, the model's call is taken as main title, NULL or FALSE mean no titles.
- `col.term`, `lwd.term`: color and line width for the 'term curve', see `lines`.
- `col.se`, `lty.se`, `lwd.se`: color, line type and line width for the 'twice-standard-error curve' when `se = TRUE`.
- `col.res`, `cex`, `pch`: color, plotting character expansion and type for partial residuals, when `partial.resid = TRUE`, see `points`.
- `ask`: logical; if TRUE, the user is asked before each plot, see `par(ask=.)`.
- `use.factor.levels`: Should x-axis ticks use factor levels or numbers for factor terms?
- `smooth`: NULL or a function with the same arguments as `panel.smooth` to draw a smooth through the partial residuals for non-factor terms
- `lty.smth`, `col.smth`, `span.smth`: Passed to `smooth`
- `ylim`: an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot.
- `plot`: if set to FALSE plots are not produced: instead a list is returned containing the data that would have been plotted.
transform.x logical vector; if an element (recycled as necessary) is TRUE, partial residuals for the corresponding term are plotted against transformed values. The model response is then a straight line, allowing a ready comparison against the data or against the curve obtained from smooth-pan.smooth.

... other graphical parameters.

Details

The model object must have a predict method that accepts type = "terms", e.g., glm in the stats package, coxph and survreg in the survival package.

For the partial.resid = TRUE option model must have a residuals method that accepts type = "partial", which lm and glm do.

The data argument should rarely be needed, but in some cases termplot may be unable to reconstruct the original data frame. Using na.action=na.exclude makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The plot = FALSE option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

Value

For plot = FALSE, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables x, y, and optionally the pointwise standard errors se. For continuous predictors x will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute "constant" copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

Examples

require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call)," ...)"))
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

## requires recommended package MASS
hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS::hills)
termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth, terms = "log(dist)", main = "Original")
```r
termplot(hills.lm, transform.x = TRUE,
    partial.resid = TRUE, smooth = panel.smooth,
    terms = "log(dist)", main = "Transformed")
```

<table>
<thead>
<tr>
<th>terms</th>
<th>Model Terms</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Description**

The function `terms` is a generic function which can be used to extract `terms` objects from various kinds of R data objects.

**Usage**

```r
terms(x, ...)
```

**Arguments**

- `x`: object used to select a method to dispatch.
- `...`: further arguments passed to or from other methods.

**Details**

There are methods for classes "aovlist", and "terms" "formula" (see `terms.formula`): the default method just extracts the terms component of the object, or failing that a "terms" attribute (as used by `model.frame`).

There are `print` and `labels` methods for class "terms": the latter prints the term labels (see `terms.object`).

**Value**

An object of class `c("terms", "formula")` which contains the `terms` representation of a symbolic model. See `terms.object` for its structure.

**References**

**See Also**

`terms.object`, `terms.formula`, `lm`, `glm`, `formula`. 
Construct a terms Object from a Formula

Description
This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a model.matrix.

Usage
```r
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, \ldots,
      allowDotAsName = FALSE)
```

Arguments
- `x` a formula.
- `specials` which functions in the formula should be marked as special in the terms object? A character vector or NULL.
- `abb` Not implemented in R.
- `data` a data frame from which the meaning of the special symbol . can be inferred. It is unused if there is no . in the formula.
- `neg.out` Not implemented in R.
- `keep.order` a logical value indicating whether the terms should keep their positions. If FALSE the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
- `simplify` should the formula be expanded and simplified, the pre-1.7.0 behaviour?
- `\ldots` further arguments passed to or from other methods.
- `allowDotAsName` normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.

Details
Not all of the options work in the same way that they do in S and not all are implemented.

Value
A terms.object object is returned. The object itself is the re-ordered (unless keep.order = TRUE) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

See Also
terms, terms.object
Description

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

Value

The object itself is simply the formula supplied to the call of `terms.formula`. The object has a number of attributes and they are used to construct the model frame:

- **factors**: A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing). Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is `numeric(0)`.
- **term.labels**: A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms. Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.
- **variables**: A call to `list` of the variables in the model.
- **intercept**: Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.
- **order**: A vector of the same length as `term.labels` indicating the order of interaction for each term.
- **response**: The index of the variable (in variables) of the response (the left hand side of the formula). Zero, if there is no response.
- **offset**: If the model contains `offset` terms there is an `offset` attribute indicating which variable(s) are offsets.
- **specials**: If a `specials` argument was given to `terms.formula` there is a `specials` attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the `variables` attribute which contain these special functions.
- **dataClasses**: Optional. A named character vector giving the classes (as given by `.MFclass`) of the variables used in a fit.
- **predvars**: Optional. An expression to help in computing predictions at new covariate values; see `makepredictcall`.

The object has class `c("terms", "formula")`.

Note

These objects are different from those found in S. In particular there is no `formula` attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the `specials` argument can be seen in the `aov` and `coxph` functions, the latter from package `survival`.
### Examples

```r
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")  # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

---

**time**

**Sampling Times of Time Series**

#### Description

time creates the vector of times at which a time series was sampled.
cycle gives the positions in the cycle of each observation.
frequency returns the number of samples per unit time and deltat the time interval between observations (see ts).

#### Usage

```r
time(x, ...)
## Default S3 method:
time(x, offset = 0, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

#### Arguments

- **x**: a univariate or multivariate time-series, or a vector or matrix.
- **offset**: can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.
- **...**: extra arguments for future methods.

#### Details

These are all generic functions, which will use the tsp attribute of x if it exists. time and cycle have methods for class ts that coerce the result to that class.

#### References

See Also

ts, start, tsp, window.
date for clock time, system.time for CPU usage.

Examples

```r
require(graphics)
cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

toeplitz  

*Form Symmetric Toeplitz Matrix*

Description

Forms a symmetric Toeplitz matrix given its first row.

Usage

toeplitz(x)

Arguments

x  the first row to form the Toeplitz matrix.

Value

The Toeplitz matrix.

Author(s)

A. Trapletti

Examples

```r
x <- 1:5
toeplitz (x)
```
**ts**  
*Time-Series Objects*

**Description**

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

**Usage**

```r
ts(data = NA, start = 1, end = numeric(), frequency = 1,
    deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )
as.ts(x, ...)
is.ts(x)
```

**Arguments**

- `data`: a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via `data.matrix`. (See also `Details`.)
- `start`: the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.
- `end`: the time of the last observation, specified in the same way as `start`.
- `frequency`: the number of observations per unit of time.
- `deltat`: the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of `frequency` or `deltat` should be provided.
- `ts.eps`: time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than `ts.eps`.
- `class`: class to be given to the result, or none if `NULL` or "none". The default is "ts" for a single series, c("mts", "ts", "matrix") for multiple series.
- `names`: a character vector of names for the series in a multiple series: defaults to the colnames of `data`, or `Series 1`, `Series 2`, ....
- `x`: an arbitrary R object.
- `...`: arguments passed to methods (unused for the default method).

**Details**

The function `ts` is used to create time-series objects. These are vector or matrices with class of "ts" (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix data is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class "ts" has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see `window`). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class "ts".
The value of argument frequency is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for frequency when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) print methods to imply a quarterly and monthly series respectively.

as.ts is generic. Its default method will use the tsp attribute of the object if it has one to set the start and end times and frequency.

is.ts tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see InternalMethods.

References

See Also
tsp, frequency, start, end, time, window; print.ts, the print method for time series objects; plot.ts, the plot method for time series objects.

For other definitions of 'time series' (e.g., time-ordered observations) see the CRAN task view at https://CRAN.R-project.org/view=TimeSeries.

Examples

require(graphics)

# 2nd Quarter of 1959
s1:10, frequency = 4, start = c(1959, 2))
print(ts(s1:10, frequency = 7, start = c(12, 2), calendar = TRUE)
# print.ts(.)

## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
           start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")

Description

Methods for objects of class "ts", typically the result of ts.
## S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts'
na.omit(object, ...)

### Arguments
- **x**: an object of class "ts" containing the values to be differenced.
- **lag**: an integer indicating which lag to use.
- **differences**: an integer indicating the order of the difference.
- **object**: a univariate or multivariate time series.
- **...**: further arguments to be passed to or from methods.

### Details
The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

### Value
For the `na.omit` method, a time series without missing values. The class of `object` will be preserved.

### See Also
- `diff`, `na.omit`, `na.fail`, `na.contiguous`.

---

### ts.plot

#### Description
Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

#### Usage
```r
ts.plot(..., gpars = list())
```

#### Arguments
- **...**: one or more univariate or multivariate time series.
- **gpars**: list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in `. . .`.

#### Value
None.
Note

Although this can be used for a single time series, plot is easier to use and is preferred.

See Also

plot.ts

Examples

```r
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
    gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

Description

Bind two or more time series.

Usage

```r
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

Arguments

... two or more univariate or multivariate time series, or objects which can coerced to time series.

dframe logical; if TRUE return the result as a data frame.

Details

As a special case, ... can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

Value

A time series object if dframe is FALSE, otherwise a data frame.

See Also

cbind.

Examples

```r
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```
Diagnostic Plots for Time-Series Fits

Description
A generic function to plot time-series diagnostics.

Usage
tsdia(gobject, gof.lag, ...)

Arguments
- object: a fitted time-series model
- gof.lag: the maximum number of lags for a Portmanteau goodness-of-fit test
- ...: further arguments to be passed to particular methods

Details
This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to gof.lag.

The methods for arima and StructTS objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

Value
None. Diagnostics are plotted.

See Also
arima, StructTS, Box.test

Examples
require(graphics)
fit <- arima(lh, c(1,0,0))
tsdia(fit)

## see also examples(arima)
(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdia(fit)
tsp

Tsp Attribute of Time-Series-like Objects

Description

tsp returns the tsp attribute (or NULL). It is included for compatibility with S version 2. tsp<- sets the tsp attribute. hasTsp ensures x has a tsp attribute, by adding one if needed.

Usage

tsp(x)
tsp(x) <- value
hasTsp(x)

Arguments

x a vector or matrix or univariate or multivariate time-series.
value a numeric vector of length 3 or NULL.

Details

The tsp attribute gives the start time in time units, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).
Assignments are checked for consistency.
Assigning NULL which removes the tsp attribute and any "ts" (or "mts") class of x.

Value

An object which differs from x only in the tsp attribute (unless NULL is assigned).
hasTsp adds, if needed, an attribute with a start time and frequency of 1 and end time NROW(x).

References

See Also

ts, time, start.
**tsSmooth**

*Use Fixed-Interval Smoothing on Time Series*

**Description**

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

**Usage**

```
  tsSmooth(object, ...)
```

**Arguments**

- `object`: a time-series fit. Currently only class "StructTS" is supported
- `...`: possible arguments for future methods.

**Value**

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

**Author(s)**

B. D. Ripley

**References**

**See Also**

*KalmanSmooth, StructTS.*
For examples consult *AirPassengers, JohnsonJohnson* and *Nile*.

---

**Tukey**

*The Studentized Range Distribution*

**Description**

Functions of the distribution of the studentized range, $R/s$, where $R$ is the range of a standard normal sample and $df \times s^2$ is independently distributed as chi-squared with $df$ degrees of freedom, see *pchisq*.

**Usage**

```
  ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
  qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```
Arguments

- **q**: vector of quantiles.
- **p**: vector of probabilities.
- **nmeans**: sample size for range (same for each group).
- **df**: degrees of freedom for $s$ (see below).
- **nranges**: number of groups whose maximum range is considered.
- **log.p**: logical; if TRUE, probabilities p are given as log(p).
- **lower.tail**: logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If $n_g = nranges$ is greater than one, $R$ is the maximum of $n_g$ groups of $nmeans$ observations each.

Value

- **ptukey**: gives the distribution function and qtukey its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

Note

A Legendre 16-point formula is used for the integral of ptukey. The computations are relatively expensive, especially for qtukey which uses a simple secant method for finding the inverse of ptukey. qtukey will be accurate to the 4th decimal place.

Source

qtukey is in part adapted from Odeh and Evans (1974).

References

See Also

- Distributions for standard distributions, including pnorm and qnorm for the corresponding functions for the normal distribution.

Examples

```r
if(interactive())
curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
(ptt <- ptukey(0:10, 2, df = 5))
(qtt <- qtukey(.95, 2, df = 2:11))
## The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```

TukeyHSD

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)

Arguments

- **x**: A fitted model object, usually an `aov` fit.
- **which**: A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
- **ordered**: A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If `ordered` is true then the calculated differences in the means will all be positive. The significant differences will be those for which the lower end point is positive.
- **conf.level**: A numeric value between zero and one giving the family-wise confidence level to use.
- **...**: Optional additional arguments. None are used at present.

Details

This is a generic function: the description here applies to the method for fits of class "aov". When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics. The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If `which` specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

Value

A list of class c("multicomp", "TukeyHSD"), with one component for each term requested in which. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p adj` giving the p-value after adjustment for the multiple comparisons.

There are print and plot methods for class "TukeyHSD". The plot method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.
The Uniform Distribution

These functions provide information about the uniform distribution on the interval from min to max. dunif gives the density, punif gives the distribution function qunif gives the quantile function and runif generates random deviates.

Usage

```
dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
```

Arguments

- `x, q` vector of quantiles.
- `p` vector of probabilities.
- `n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
- `min, max` lower and upper limits of the distribution. Must be finite.
- `log, log.p` logical; if TRUE, probabilities p are given as log(p).
- `lower.tail` logical; if TRUE (default), probabilities are \( P[X \leq x] \), otherwise, \( P[X > x] \).
Details

If \( \min \) or \( \max \) are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

\[
f(x) = \frac{1}{\max - \min}
\]

for \( \min \leq x \leq \max \).

For the case of \( u := \min == \max \), the limit case of \( X \equiv u \) is assumed, although there is no density in that case and \( \text{dunif} \) will return \( \text{NaN} \) (the error condition).

\( \text{runif} \) will not generate either of the extreme values unless \( \max = \min \) or \( \max - \min \) is small compared to \( \min \), and in particular not for the default arguments.

Value

dunif gives the density, punif gives the distribution function, qunif gives the quantile function, and runif generates random deviates.

The length of the result is determined by \( n \) for \( \text{runif} \), and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than \( n \) are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See \( \texttt{Random.seed} \) for more information on \( \texttt{R} \)'s random number generation algorithms.

References

See Also

\( \texttt{RNG} \) about random number generation in \( \texttt{R} \).

\( \texttt{Distributions} \) for other standard distributions.

Examples

\[
u <- \text{runif}(20)
\]

\[
## The following relations always hold :
punif(u) == u
dunif(u) == 1
\]

\[
\text{var(\text{runif}(10000)))} \quad #\sim = 1/12 \approx .08333
\]
uniroot

One Dimensional Root (Zero) Finding

Description

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct interval \( c(\text{lower}, \text{upper}) \) if \( \text{sign}(f(x)) \) does not satisfy the requirements at the interval end points; see the ‘Details’ section.

Usage

```r
uniroot(f, interval, ..., lower = min(interval), upper = max(interval), f.lower = f(lower, ...), f.upper = f(upper, ...), extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE, tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

Arguments

- **f**: the function for which the root is sought.
- **interval**: a vector containing the end-points of the interval to be searched for the root.
- **...**: additional named or unnamed arguments to be passed to `f`
- **lower, upper**: the lower and upper end points of the interval to be searched.
- **f.lower, f.upper**: the same as `f(upper)` and `f(lower)`, respectively. Passing these values from the caller where they are often known is more economical as soon as `f()` contains non-trivial computations.
- **extendInt**: character string specifying if the interval \( c(\text{lower}, \text{upper}) \) should be extended or directly produce an error when `f()` does not have differing signs at the end-points. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated.
- **check.conv**: logical indicating whether a convergence warning of the underlying `uniroot` should be caught as an error and if non-convergence in `maxiter` iterations should be an error instead of a warning.
- **tol**: the desired accuracy (convergence tolerance).
- **maxiter**: the maximum number of iterations.
- **trace**: integer number; if positive, tracing information is produced. Higher values giving more details.

Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval \([l, u]\) satisfies \( f(l) \cdot f(u) \leq 0 \).
If it is known how \( f \) changes sign at the root \( x_0 \), that is, if the function is increasing or decreasing there, `extendInt` can (and typically should) be specified as "upX" (for "upward crossing") or "downX", respectively. Equivalently, define \( S := \pm 1 \), to require \( S = \text{sign}(f(x_0 + \epsilon)) \) at the solution. In that case, the search interval \([l, u]\) possibly is extended to be such that \( S \cdot f(l) \leq 0 \) and \( S \cdot f(u) \geq 0 \).

`uniroot()` uses Fortran subroutine "zeroin" (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if \( f(x) \approx 0 \) or the change in \( x \) for one step of the algorithm is less than \( \text{tol} \) (plus an allowance for representation error in \( x \)).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

\( f \) will be called as \( f(x, \ldots) \) for a numeric value of \( x \).

The argument passed to `f` has special semantics and used to be shared between calls. The function should not copy it.

**Value**

A list with at least four components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is `NA`.)

Further components may be added in future: component `init.it` was added in R 3.1.0.

**Source**

Based on 'zeroin.c' in http://www.netlib.org/c/brent.shar.

**References**

**See Also**

`polyroot` for all complex roots of a polynomial; `optimize, nlm`.

**Examples**

```r
require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
##
f <- function(x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
             tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
             tol = 1e-10))
```
## Find the smallest value \( x \) for which \( \exp(x) > 0 \) (numerically):

\[
r <- \text{uniroot}(\text{function}(x) 1e80*\exp(x) - 1e-300, c(-1000, 0), \text{tol} = 1e-15)
\]

\[
\text{str}(r, \text{digits.d} = 15) \quad \# \text{around -745, depending on the platform.}
\]

\[
\exp(r$\text{root}) \quad \# = 0, \text{but not for } r$\text{root} \times 0.999...
\]

\[
\text{minexp} <- r$\text{root} \times (1 - 10*.\text{Machine$\text{double.eps}})
\]

\[
\exp(minexp) \quad \# \text{typically denormalized}
\]

###--- uniroot() with new interval extension + checking features:  

\[
f1 <- \text{function}(x) (121 - x^2)/(x^2+1)
\]

\[
f2 <- \text{function}(x) \exp(-x)*(x - 12)
\]

\[
\text{try(uniroot(f1, c(0,10)))}
\]

\[
\text{try(uniroot(f2, c(0, 2)))}
\]

\[
\#---> error: f() .. end points not of opposite sign
\]

### where as 'extendInt="yes"' simply first enlarges the search interval:

\[
u1 <- \text{uniroot}(f1, c(0,10), \text{extendInt="yes", trace=1})
\]

\[
u2 <- \text{uniroot}(f2, c(0,2), \text{extendInt="yes", trace=2})
\]

\[
\text{stopifnot(all.equal(u1$\text{root}, 11, tolerance = 1e-5),}
\]

\[
\text{all.equal(u2$\text{root}, 12, tolerance = 6e-6))}
\]

### The *danger* of interval extension:

### No way to find a zero of a positive function, but

### numerically, \( f(-\|M\|) \) becomes zero :

\[
\text{u3} <- \text{uniroot}(\exp, c(0,2), \text{extendInt="yes", trace=TRUE})
\]

### Nonsense example (**must** give an error):

\[
\text{tools::assertCondition( uniroot(\text{function}(x) 1, 0:1, \text{extendInt="yes"},}
\]

\[
\text{"error", verbose=TRUE})
\]

### Convergence checking :

\[
sinc <- \text{function}(x) \text{ifelse(x == 0, 1, sin(x)/x)}
\]

\[
\text{curve(sinc, -6,18); abline(h=0,v=0, lty=3, col=adjustcolor("gray", 0.8))}
\]

\[
\text{uniroot(sinc, c(0,5), \text{extendInt="yes", maxiter=4}) #-> "just" a warning}
\]

### now with \text{check.conv=TRUE}, must signal a convergence error :

\[
\text{uniroot(sinc, c(0,5), \text{extendInt="yes", maxiter=4, check.conv=TRUE})}
\]

### Weibull cumulative hazard (example origin, Ravi Varadhan):

\[
cumhaz <- \text{function}(t, a, b) b * (t/b)^a
\]

\[
froot <- \text{function}(x, u, a, b) \text{cumhaz}(x, a, b) - u
\]

\[
n <- \text{1000}
\]

\[
u <- -\log(\text{runif}(n))
\]

\[
a <- 1/2
\]

\[
b <- 1
\]

### Find failure times

\[
\text{ru} <- \text{sapply(u, function(x)}
\]

\[
\text{uniroot(froot, u=x, a=a, b=b, \text{interval}= c(1.e-14, 1e04),}
\]

## uniroot
### Description

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

“Extracting the call” in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x$call. Because of this, update() will often work (via its default method) on new model classes, either automatically, or by providing a simple getCall() method for that class.

### Usage

```r
update(object, ...)  
```

```r  
## Default S3 method: 
update(object, formula., ..., evaluate = TRUE)  
```

### Arguments

- **object, x**
  
  An existing fit from a model function such as `lm`, `glm` and many others.

- **formula.**
  
  Changes to the formula – see `update.formula` for details.

- **...**
  
  Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.

- **evaluate**
  
  If true evaluate the new call else return the call.

### Value

If `evaluate = TRUE` the fitted object, otherwise the updated call.

### References

update.formula

Description

update.formula is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

Usage

## S3 method for class 'formula'
update(old, new, ...)

Arguments

old
  a model formula to be updated.
new
  a formula giving a template which specifies how to update.
...
  further arguments passed to or from other methods.

Details

Either or both of old and new can be objects such as length-one character vectors which can be coerced to a formula via as.formula.

The function works by first identifying the left-hand side and right-hand side of the old formula. It then examines the new formula and substitutes the lhs of the old formula for any occurrence of ‘.’ on the left of new, and substitutes the rhs of the old formula for any occurrence of ‘.’ on the right of new. The result is then simplified via terms.formula(simplify = TRUE).

Value

The updated formula is returned. The environment of the result is that of old.
F Test to Compare Two Variances

Description

Performs an F test to compare the variances of two samples from normal populations.

Usage

var.test(x, ...)  
## Default S3 method:  
var.test(x, y, ratio = 1,  
  alternative = c("two.sided", "less", "greater"),  
  conf.level = 0.95, ...)  
## S3 method for class 'formula'  
var.test(formula, data, subset, na.action, ...)  

Arguments  

x, y numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").  
ratio the hypothesized ratio of the population variances of x and y.  
alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.  
conf.level confidence level for the returned confidence interval.  
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.  
data an optional matrix or data frame (or similar: see `model.frame`) containing the variables in the formula `formula`. By default the variables are taken from environment(`formula`).  
subset an optional vector specifying a subset of observations to be used.  
na.action a function which indicates what should happen when the data contain NAs. Defaults to `getOption("na.action")`.  
... further arguments to be passed to or from methods.
Details

The null hypothesis is that the ratio of the variances of the populations from which \( x \) and \( y \) were drawn, or in the data to which the linear models \( x \) and \( y \) were fitted, is equal to \( \text{ratio} \).

Value

A list with class "htest" containing the following components:

- **statistic** the value of the F test statistic.
- **parameter** the degrees of the freedom of the F distribution of the test statistic.
- **p.value** the p-value of the test.
- **conf.int** a confidence interval for the ratio of the population variances.
- **estimate** the ratio of the sample variances of \( x \) and \( y \).
- **null.value** the ratio of population variances under the null.
- **alternative** a character string describing the alternative hypothesis.
- **method** the character string "F test to compare two variances".
- **data.name** a character string giving the names of the data.

See Also

- **bartlett.test** for testing homogeneity of variances in more than two samples from normal distributions;
- **ansari.test** and **mood.test** for two rank based (nonparametric) two-sample tests for difference in scale.

Examples

```r
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

---

### varimax

**Rotation Methods for Factor Analysis**

Description

These functions ‘rotate’ loading matrices in factor analysis.

Usage

```r
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

Arguments

- **x** A loadings matrix, with \( p \) rows and \( k < p \) columns
- **m** The power used the target for promax. Values of 2 to 4 are recommended.
- **normalize** logical. Should Kaiser normalization be performed? If so the rows of \( x \) are re-scaled to unit length before rotation, and scaled back afterwards.
- **eps** The tolerance for stopping: the relative change in the sum of singular values.
Details

These seek a ‘rotation’ of the factors \( x \times T \) that aims to clarify the structure of the loadings matrix. The matrix \( T \) is a rotation (possibly with reflection) for varimax, but a general linear transformation for promax, with the variance of the factors being preserved.

Value

A list with components

- **loadings**: The ‘rotated’ loadings matrix, \( x \times T \), of class "loadings".
- **rotmat**: The ‘rotation’ matrix.

References

See Also

- factanal, Harman74.cor.

Examples

```r
## varimax with normalize = TRUE is the default
fa <- factanal(~., 2, data = swiss)
varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

---

### vcov

**Calculate Variance-Covariance Matrix for a Fitted Model Object**

Description

Returns the variance-covariance matrix of the main parameters of a fitted model object. The “main” parameters of model correspond to those returned by `coef`, and typically do not contain a nuisance scale parameter (`sigma`).

Usage

```r
vcov(object, ...)  
## S3 method for class 'lm'
vcov(object, complete = TRUE, ...)  
## and also for '[summary.]glm' and 'mlm'
## S3 method for class 'aov'
vcov(object, complete = FALSE, ...)  

.vcov.aliased(aliased, vc, complete = TRUE)
```
Weibull

Arguments

object a fitted model object, typically. Sometimes also a summary() object of such a fitted model.

complete for the aov, lm, glm, mlm, and where applicable summary.lm etc methods: logical indicating if the full variance-covariance matrix should be returned also in case of an over-determined system where some coefficients are undefined and coef(.) contains NAs correspondingly. When complete = TRUE, vcov() is compatible with coef() also in this singular case.

... additional arguments for method functions. For the glm method this can be used to pass a dispersion parameter.

aliased a logical vector typically identical to is.na(coef(.)) indicating which coefficients are ‘aliased’.

vc a variance-covariance matrix, typically “incomplete”, i.e., with no rows and columns for aliased coefficients.

Details

vcov() is a generic function and functions with names beginning in vcov. will be methods for this function. Classes with methods for this function include: lm, mlm, glm, nls, summary.lm, summary.glm, negbin, polr, rlm (in package MASS), multinom (in package nnet) gls, lme (in package nlme), coxph and survreg (in package survival).

(vcov() methods for summary objects allow more efficient and still encapsulated access when both summary(mod) and vcov(mod) are needed.)

.vcov.aliased() is an auxiliary function useful for vcov method implementations which have to deal with singular model fits encoded via NA coefficients: It augments a vcov–matrix vc by NA rows and columns where needed, i.e., when some entries of aliased are true and vc is of smaller dimension than length(aliased).

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the coef method.

When some coefficients of the (linear) model are undetermined and hence NA because of linearly dependent terms (or an “over specified” model), also called “aliased”, see alias, then since R version 3.5.0, vcov() (iff complete = TRUE, i.e., by default for lm etc, but not for aov) contains corresponding rows and columns of NAs, wherever coef() has always contained such NAs.

The Weibull Distribution

Description

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters shape and scale.
Weibull

Usage

dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)

Arguments

x, q  vector of quantiles.
p  vector of probabilities.
n  number of observations. If length(n) > 1, the length is taken to be the number
required.
shape, scale  shape and scale parameters, the latter defaulting to 1.
log, log.p  logical; if TRUE, probabilities p are given as log(p).
lower.tail  logical; if TRUE (default), probabilities are
            P[X ≤ x], otherwise, P[X > x].

Details

The Weibull distribution with shape parameter a and scale parameter σ has density given by

\[ f(x) = \frac{a}{\sigma} \left(\frac{x}{\sigma}\right)^{a-1} \exp\left(-\left(\frac{x}{\sigma}\right)^a\right) \]

for \( x > 0 \). The cumulative distribution function is \( F(x) = 1 - \exp\left(-\left(\frac{x}{\sigma}\right)^a\right) \) on \( x > 0 \), the mean is \( E(X) = \sigma \Gamma\left(1 + \frac{1}{a}\right) \), and the \( \text{Var}(X) = \sigma^2 \left(\Gamma\left(1 + \frac{2}{a}\right) - \left(\Gamma\left(1 + \frac{1}{a}\right)\right)^2\right) \).

Value

dweibull gives the density, pweibull gives the distribution function, qweibull gives the quantile function, and rweibull generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by n for rweibull, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than n are recycled to the length of the result. Only the first elements of the logical arguments are used.

Note

The cumulative hazard \( H(t) = -\log(1 - F(t)) \) is

\[-\text{pweibull}(t, a, b, \text{lower} = \text{FALSE}, \text{log} = \text{TRUE})\]

which is just \( H(t) = (t/b)^a \).

Source

[dpq]weibull are calculated directly from the definitions. rweibull uses inversion.

References

See Also

Distributions for other standard distributions, including the Exponential which is a special case of the Weibull distribution.

Examples

```r
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
        -(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

---

**weighted.mean**  
*Weighted Arithmetic Mean*

**Description**

Compute a weighted mean.

**Usage**

```r
weighted.mean(x, w, ...)  
## Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)
```

**Arguments**

- `x` an object containing the values whose weighted mean is to be computed.
- `w` a numerical vector of weights the same length as `x` giving the weights to use for elements of `x`.
- `...` arguments to be passed to or from methods.
- `na.rm` a logical value indicating whether NA values in `x` should be stripped before the computation proceeds.

**Details**

This is a generic function and methods can be defined for the first argument `x`: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which `[`, multiplication, division and `sum` have suitable methods, including complex vectors.

If `w` is missing then all elements of `x` are given the same weight, otherwise the weights coerced to numeric by `as.numeric` and normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in `w` are not handled specially and so give a missing value as the result. However, zero weights *are* handled specially and the corresponding `x` values are omitted from the sum.
weighted.residuals

Value

For the default method, a length-one numeric vector.

See Also

mean

Examples

## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7,3.3,3.5,2.8)
xm <- weighted.mean(x, wt)

weighted.residuals

Compute Weighted Residuals

Description

Computed weighted residuals from a linear model fit.

Usage

weighted.residuals(obj, drop0 = TRUE)

Arguments

obj R object, typically of class lm or glm.
drop0 logical. If TRUE, drop all cases with weights == 0.

Details

Weighted residuals are based on the deviance residuals, which for a lm fit are the raw residuals \( R_i \) multiplied by \( \sqrt{w_i} \), where \( w_i \) are the weights as specified in lm’s call.

Dropping cases with weights zero is compatible with influence and related functions.

Value

Numeric vector of length \( n' \), where \( n' \) is the number of of non-0 weights (drop0 = TRUE) or the number of observations, otherwise.

See Also

residuals, lm.influence, etc.
### Examples

```r
## following on from example(lm)
all.equal(weighted.residuals(lm.D9), residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

---

weights | Extract Model Weights

---

### Description

weights is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of `napredict` methods to compensate for the omission of missing values. The default methods does so.

### Usage

```r
weights(object, ...)  
```

### Arguments

- `object`: an object for which the extraction of model weights is meaningful.
- `...`: other arguments passed to methods.

### Value

Weights extracted from the object object: the default method looks for component "weights" and if not NULL calls `napredict` on it.

### References

### See Also

- `weights.glm`
Description

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as 'Mann-Whitney' test.

Usage

wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
alternative = c("two.sided", "less", "greater"),
mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
conf.int = FALSE, conf.level = 0.95, ...)

## S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action, ...)

Arguments

x numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted.
y an optional numeric vector of data values: as with x non-finite values will be omitted.
alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
mu a number specifying an optional parameter used to form the null hypothesis. See 'Details'.
paired a logical indicating whether you want a paired test.
exact a logical indicating whether an exact p-value should be computed.
correct a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
conf.int a logical indicating whether a confidence interval should be computed.
conf.level confidence level of the interval.
formula a formula of the form lhs ~ rhs where lhs is a numeric variable giving the data values and rhs a factor with two levels giving the corresponding groups.
data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset an optional vector specifying a subset of observations to be used.
na.action a function which indicates what should happen when the data contain NAs. Defaults to getOption("na.action").
... further arguments to be passed to or from methods.
Details

The formula interface is only applicable for the 2-sample tests.

If only x is given, or if both x and y are given and paired is TRUE, a Wilcoxon signed rank test of
the null that the distribution of x (in the one sample case) or of x - y (in the paired two sample
case) is symmetric about mu is performed.

Otherwise, if both x and y are given and paired is FALSE, a Wilcoxon rank sum test (equivalent
to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the
distributions of x and y differ by a location shift of mu and the alternative is that they differ by some
other location shift (and the one-sided alternative “greater” is that x is shifted to the right of y).

By default (if exact is not specified), an exact p-value is computed if the samples contain less than
50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally (if argument conf.int is true), a nonparametric confidence interval and an estimator
for the pseudomedian (one-sample case) or for the difference of the location parameters x - y is
computed. (The pseudomedian of a distribution F is the median of the distribution of (u + v)/2,
where u and v are independent, each with distribution F. If F is symmetric, then the pseudomedian
and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case
the estimator for the difference in location parameters does not estimate the difference in medians
(a common misconception) but rather the median of the difference between a sample from x and a
sample from y.

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in
Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence
interval and point estimate are based on normal approximations. These are continuity-corrected for
the interval but not the estimate (as the correction depends on the alternative).

With small samples it may not be possible to achieve very high confidence interval coverages. If
this happens a warning will be given and an interval with lower coverage will be substituted.

When x (and y if applicable) are valid, the function now always returns, also in the
conf.int = TRUE case when a confidence interval cannot be computed, in which case the interval
boundaries and sometimes the estimate now contain NaN.

Value

A list with class "htest" containing the following components:

- statistic: the value of the test statistic with a name describing it.
- parameter: the parameter(s) for the exact distribution of the test statistic.
- p.value: the p-value for the test.
- null.value: the location parameter mu.
- alternative: a character string describing the alternative hypothesis.
- method: the type of test applied.
- data.name: a character string giving the names of the data.
- conf.int: a confidence interval for the location parameter. (Only present if argument
  conf.int = TRUE.)
- estimate: an estimate of the location parameter. (Only present if argument
  conf.int = TRUE.)

Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is
exceeded) if exact = TRUE and one sample is large (several thousands or more).
Note
The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: \( R \) subtracts and S-PLUS does not, giving a value which is larger by \( m(m+1)/2 \) for a first sample of size \( m \). (It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

\( R \)'s value can also be computed as the number of all pairs \((x[i], y[j])\) for which \( y[j] \) is not greater than \( x[i] \), the most common definition of the Mann-Whitney test.

```
wilcox.test(rnorm(10), rnorm(10, 2), conf.int = TRUE)

## Formula interface.
boxplot(Ozone ~ Month, data = airquality)
wilcox.test(Ozone ~ Month, data = airquality, 
subset = Month %in% c(5, 8))

Wilcoxon

Distribution of the Wilcoxon Rank Sum Statistic

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size m and n, respectively.

Usage

dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)

Arguments

- x, q: vector of quantiles.
- p: vector of probabilities.
- nn: number of observations. If length(nn) > 1, the length is taken to be the number required.
- m, n: numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.
- log, log.p: logical; if TRUE, probabilities p are given as log(p).
- lower.tail: logical; if TRUE (default), probabilities are P[X ≤ x], otherwise, P[X > x].

Details

This distribution is obtained as follows. Let x and y be two random, independent samples of size m and n. Then the Wilcoxon rank sum statistic is the number of all pairs (x[i], y[j]) for which y[j] is not greater than x[i]. This statistic takes values between 0 and m * n, and its mean and variance are m * n / 2 and m * n * (m + n + 1) / 12, respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

Value

dwilcox gives the density, pwilcox gives the distribution function, qwilcox gives the quantile function, and rwilcox generates random deviates.

The length of the result is determined by nn for rwilcox, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than nn are recycled to the length of the result. Only the first elements of the logical arguments are used.
Warning
These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note
S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see \texttt{wilcox.test} for details.

Author(s)
Kurt Hornik

Source
These are calculated via recursion, based on \texttt{cwilcox(k, m, n)}, the number of choices with statistic \texttt{k} from samples of size \texttt{m} and \texttt{n}, which is itself calculated recursively and the results cached. Then \texttt{dwilcox} and \texttt{pwilcox} sum appropriate values of \texttt{cwilcox}, and \texttt{qwilcox} is based on inversion. \texttt{rwilcox} generates a random permutation of ranks and evaluates the statistic.

See Also
\texttt{wilcox.test} to calculate the statistic from data, find p values and so on.

Distributions for standard distributions, including \texttt{dsignrank} for the distribution of the one-sample Wilcoxon signed rank statistic.

Examples

\begin{verbatim}
require(graphics)
x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)"
)
plot(x, Fx, type = "s", col = "blue",
     main = "Distribution of Wilcoxon-Statist.(n=6, m=4)"
)
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back

N <- 200
hist(U <- rwilcox(N, m = 4,n = 6), breaks = 0:25 - 1/2,
     border = "red", col = "pink", sub = paste("N =",N))
text(n-.2, n+.5, labels = tU, col = "red")

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
       main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                   "Wilcoxon Statistic. (m=4, n=6)", sep = "\n"))

n <- as.numeric(names(print(tU <- table(U))))
text(n*.2, n+.5, labels = tU, col = "red")
\end{verbatim}
Description

window is a generic function which extracts the subset of the object x observed between the times start and end. If a frequency is specified, the series is then re-sampled at the new frequency.

Usage

window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
    frequency = NULL, deltat = NULL, extend = FALSE, ...)

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value

Arguments

x a time-series (or other object if not replacing values).
start the start time of the period of interest.
end the end time of the period of interest.
frequency, deltat the new frequency can be specified by either (or both if they are consistent).
extend logical. If true, the start and end values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
... further arguments passed to or from other methods.
value replacement values.

Details

The start and end times can be specified as for ts. If there is no observation at the new start or end, the immediately following (start) or preceding (end) observation time is used.

The replacement function has a method for ts objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. window.default will return a vector or matrix with an appropriate tsp attribute.

window.ts differs from window.default only in ensuring the result is a ts object.

If extend = TRUE the series will be padded with NAs if needed.
xtabs

Cross Tabulation

Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE, na.action, addNA = FALSE, exclude = if(!addNA) c(NA, NaN), drop.unused.levels = FALSE)

## S3 method for class 'xtabs'
print(x, na.print = "", ...)  

Arguments

formula a formula object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.

data an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).

subset an optional vector specifying a subset of observations to be used.
sparse logical specifying if the result should be a *sparse* matrix, i.e., inheriting from `sparseMatrix` Only works for two factors (since there are no higher-order sparse array classes yet).

na.action a function which indicates what should happen when the data contain NAs. If unspecified, and addNA is true, this is set to `na.pass`. When it is `na.pass` and formula has a left hand side (with counts), `sum(*, na.rm = TRUE)` is used instead of `sum(*)` for the counts.

addNA logical indicating if NAs should get a separate level and be counted, using `addNA(*, ifany=TRUE)` and setting the default for `na.action`.

exclude a vector of values to be excluded when forming the set of levels of the classifying factors.

drop.unused.levels a logical indicating whether to drop unused levels in the classifying factors. If this is `FALSE` and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.

x an object of class "xtabs".

na.print character string (or NULL) indicating how NA are printed. The default (""") does not show NAs clearly, and `na.print = "NA"` maybe advisable instead.

... further arguments passed to or from other methods.

Details

There is a summary method for contingency table objects created by `table` or `xtabs(*, sparse = FALSE)`, which gives basic information and performs a chi-squared test for independence of factors (note that the function `chisq.test` currently only handles 2-d tables).

If a left hand side is given in formula, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

For variables in formula which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

In R versions before 3.4.0, e.g., when `na.action = na.pass`, sometimes zeroes (0) were returned instead of NAs.

Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a "call" attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package `Matrix`.

See Also

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package `Matrix`.
Examples

```r
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
tabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(tabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ... 
ftable(tabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form. 
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts 
## in variable 'Freq'.
DF
## Nice for taking margins ... 
tabs(Freq ~ Gender + Admit, DF)
## And for testing independence ... 
summary(tabs(Freq ~ ., DF))

## with NA's 
DN <- DF; DN[cbind(8:9, c(1:2,4:1))] <- NA; DN 
tools::assertError( # 'na.fail' should fail :
  tabs(Freq ~ Gender + Admit, DN, na.action=na.fail))
tabs(Freq ~ Gender + Admit, DN)
tabs(Freq ~ Gender + Admit, DN, na.action = na.pass)
## The Female:Rejected combination has NA 'Freq' (and NA prints 'invisibly' as '')
tabs(Freq ~ Gender + Admit, DN, addNA = TRUE) # ==> count NAs

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep_len(1:9, 54)
ftable(tabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----

if(require("Matrix")) {
  ## similar to 'nlme's 'ergoStool' :
d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
  Subj = gl(9, 4, 36*4))
print(tabs(~ Type + Subj, data = d.ergo)) # 4 replicates each
set.seed(15) # a subset of cases:
print(tabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE))

## Hypothetical two-level setup:
inner <- factor(sample(letters[1:25], 100, replace = TRUE))
inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
print(tabs(~ inner + outer, fr, sparse = TRUE))
}
```
Chapter 11

The stats4 package

stats4-package  Statistical Functions using S4 Classes

Description
Statistical Functions using S4 classes.

Details
This package contains functions and classes for statistics using the S version 4 class system.
The methods currently support maximum likelihood (function mle() returning class "mle"), including methods for logLik for use with AIC.

Author(s)
R Core Team and contributors worldwide
Maintainer: R Core Team <R-core@r-project.org>

coef-methods  Methods for Function coef in Package stats4

Description
Extract the coefficient vector from "mle" objects.

Methods
signature(object = "ANY") Generic function: see coef.
signature(object = "mle") Extract the full coefficient vector (including any fixed coefficients) from the fit.
signature(object = "summary.mle") Extract the coefficient vector and standard errors from the summary of the fit.
confint-methods

Methods for Function confint in Package stats4

Description

Generate confidence intervals

Methods

signature(object = "ANY") Generic function: see confint.
signature(object = "mle") First generate profile and then confidence intervals from the profile.
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

logLik-methods

Methods for Function logLik in Package stats4

Description

Extract the maximized log-likelihood from "mle" objects.

Methods

signature(object = "ANY") Generic function: see logLik.
signature(object = "mle") Extract log-likelihood from the fit.

Note

The mle method does not know about the number of observations unless nobs was specified on the call and so may not be suitable for use with BIC.

mle

Maximum Likelihood Estimation

Description

Estimate parameters by the method of maximum likelihood.

Usage

mle(minuslogl, start = formals(minuslogl), method = "BFGS", fixed = list(), nobs, ...)
Arguments

- **minuslogl**: Function to calculate negative log-likelihood.
- **start**: Named list. Initial values for optimizer.
- **method**: Optimization method to use. See `optim`.
- **fixed**: Named list. Parameter values to keep fixed during optimization.
- **nobs**: Optional integer: the number of observations, to be used for e.g. computing BIC.
- **...**: Further arguments to pass to `optim`.

Details

The `optim` optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum.

Value

An object of class **mle-class**.

Note

Be careful to note that the argument is -log L (not -2 log L). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

See Also

- **mle-class**

Examples

```r
## Avoid printing to unwarranted accuracy
od <- options(digits = 5)
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

## Easy one-dimensional MLE:
nlL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))
# For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
            method = "Brent", lower = 1, upper = 20)
stopifnot(nobs(fit0) == length(y))

## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))

mle(ll, fixed = list(xhalf = 6))
## alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, method = "L-BFGS-B", lower = rep(0, 2))
```
mle-class

Class "mle" for Results of Maximum Likelihood Estimation

Description

This class encapsulates results of a generic maximum likelihood procedure.

Objects from the Class

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

Slots

call: Object of class "language". The call to `mle`.

coef: Object of class "numeric". Estimated parameters.

fullcoef: Object of class "numeric". Fixed and estimated parameters.

vcov: Object of class "matrix". Approximate variance-covariance matrix.

min: Object of class "numeric". Minimum value of objective function.

details: a "list", as returned from `optim`.

minuslogl: Object of class "function". The negative loglikelihood function.

nobs: "integer" of length one. The number of observations (often NA, when not set in call explicitly).

method: Object of class "character". The optimization method used.
Methods

confint signature(object = "mle"): Confidence intervals from likelihood profiles.
logLik signature(object = "mle"): Extract maximized log-likelihood.
profile signature(fitted = "mle"): Likelihood profile generation.
nobs signature(object = "mle"): Number of observations, here simply accessing the nobs slot mentioned above.
show signature(object = "mle"): Display object briefly.
summary signature(object = "mle"): Generate object summary.
update signature(object = "mle"): Update fit.
vcov signature(object = "mle"): Extract variance-covariance matrix.

Description

Plot profile likelihoods for "mle" objects.

Usage

## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)

Arguments

x an object of class "profile.mle"
levels levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly.
conf a numeric vector of confidence levels for profile-based confidence intervals on the parameters.
nseg an integer value giving the number of segments to use in the spline interpolation of the profile t curves.
absVal a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.
... other arguments to the plot function can be passed here.

Methods

signature(x = "ANY", y = "ANY") Generic function: see plot.
signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.
Methods for Function profile in Package stats4

Description

Profile likelihood for "mle" objects.

Usage

```r
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
        zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
        trace = FALSE, ...)
```

Arguments

- `fitted`: Object to be profiled
- `which`: Optionally select subset of parameters to profile.
- `maxsteps`: Maximum number of steps to bracket `zmax`.
- `alpha`: Significance level corresponding to `zmax`, based on a Scheffe-style multiple testing interval. Ignored if `zmax` is specified.
- `zmax`: Cutoff for the profiled value of the signed root-likelihood.
- `del`: Initial stepsize on root-likelihood scale.
- `trace`: Logical. Print intermediate results.
- `...`: Currently unused.

Details

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

Value

An object of class "profile.mle", see "profile.mle-class".

Methods

- `signature(fitted = "ANY")` Generic function: see `profile`.
- `signature(fitted = "mle")` Profile the likelihood in the vicinity of the optimum of an "mle" object.
profile.mle-class

Class "profile.mle"; Profiling information for "mle" object

Description

Likelihood profiles along each parameter of likelihood function

Objects from the Class

Objects can be created by calls of the form `new("profile.mle", ...), but most often by invoking `profile` on an "mle" object.

Slots

- `profile`: Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.
- `summary`: Object of class "summary.mle". Summary of object being profiled.

Methods

- `confint` signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.
- `plot` signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

See Also

`mle, mle-class, summary.mle-class`

show-methods

Methods for Function show in Package `stats4`

Description

Show objects of classes `mle` and `summary.mle`

Methods

- `signature(object = "mle")` Print simple summary of `mle` object. Just the coefficients and the call.
- `signature(object = "summary.mle")` Shows call, table of coefficients and standard errors, and $-2\log L$. 
Methods for Function `summary` in Package `stats4`

Description

Summarize objects

Methods

- `signature(object = "ANY")` Generic function
- `signature(object = "mle")` Generate a summary as an object of class "summary.mle", containing estimates, asymptotic SE, and value of \(-2 \log L\).

Class "summary.mle", Summary of "mle" Objects

Description

Extract of "mle" object

Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...)` but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

Slots

- `call`: Object of class "language" The call that generated the "mle" object.
- `coef`: Object of class "matrix". Estimated coefficients and standard errors
- `m2logL`: Object of class "numeric". Minus twice the log likelihood.

Methods

- `show signature(object = "summary.mle")`: Pretty-prints object
- `coef signature(object = "summary.mle")`: Extracts the contents of the coef slot

See Also

`summary.mle`, `mle-class`
**update-methods**

*Methods for Function update in Package stats4*

### Description

Update "mle" objects.

### Usage

```r
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

### Arguments

- `object` An existing fit.
- `...` Additional arguments to the call, or arguments with changed values. Use `name = NULL` to remove the argument name.
- `evaluate` If true evaluate the new call else return the call.

### Methods

- `signature(object = "ANY")` Generic function: see `update`.
- `signature(object = "mle")` Update a fit.

### Examples

```r
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

**vcov-methods**

*Methods for Function vcov in Package stats4*

### Description

Extract the approximate variance-covariance matrix from "mle" objects.

### Methods

- `signature(object = "ANY")` Generic function: see `vcov`.
- `signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).
Chapter 12

The tcltk package

---

tcltk-package  
Tcl/Tk Interface

Description

Interface and language bindings to Tcl/Tk GUI elements.

Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See TkWidgets for a list of supported widgets, TkWidgetcmds for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use ls("package:tcltk").

Note that Tk will not be initialized if there is no DISPLAY variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on tcltk in a session that does not actually use it (e.g., during installation).

---

TclInterface  
Low-level Tcl/Tk Interface

Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class tclVar and the C level interface to Tcl objects is accessed via objects of class tc10bj.
Usage

.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
## S3 method for class 'tclVar'
as.character(x, ...)
## S3 method for class 'tclVar'
tclvalue(x)
## S3 replacement method for class 'tclVar'
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray'
x[[...]]
## S3 replacement method for class 'tclArray'
x[[...]] <- value
## S3 method for class 'tclArray'
x$i
## S3 replacement method for class 'tclArray'
x$i <- value

## S3 method for class 'tclArray'
names(x)
## S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x)
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'
as.character(x, ...)
## S3 method for class 'tclObj'
as.integer(x, ...)
## S3 method for class 'tclObj'
as.double(x, ...)
## S3 method for class 'tclObj'
as.logical(x, ...)
## S3 method for class 'tclObj'
as.raw(x, ...)
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
tclVersion()

### Arguments

- **objv**: a named vector of Tcl objects
- **win**: a window structure
- **x**: an object
- **i**: character or (unquoted) name
- **drop**: logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one
- **value**: For tclvalue assignments, a character string. For tclObj assignments, an object of class tclObj
- **ID**: a window ID
- **parent**: a window which becomes the parent of the resulting window
- **path**: path to a directory containing Tcl packages
- **package**: a Tcl package name
- **warn**: logical. Warn if not found?
- **...**: Additional arguments. See below.
- **init**: initialization value

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level .Tcl sends a command as a text string to the Tcl interpreter and returns the result as an object of class tclObj (see below). A newer variant .Tcl.args converts an R argument list of tag = value pairs to the Tcl -option value style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with no subsequent value tag = NULL can be used. Most values are just converted to character mode and inserted in
the command string, but window objects are passed using their ID string, and callbacks are passed via the result of .Tcl.callback. Tags are converted to option flags simply by prepending a -

.Tcl.args.objv serves a similar purpose as .Tcl.args but produces a list of tclObj objects suitable for passing to .Tcl.objv. The names of the list are converted to Tcl option style internally by .Tcl.objv.

Callbacks can be either atomic callbacks handled by .Tcl.callback or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the break expression is translated directly to the Tcl counterpart. .Tcl.callback converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode "call" followed by an environment. The return value in the first case is of the form R_call 0x408b94d4 in which the hexadecimal number is the memory address of the function. In the second case it will be of the form R_call_lang 0x8a95904 0x819bfd0. For expressions, a sequence of similar items is generated, separated by semicolons. .Tcl.args takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class tkwin which are lists containing a ID field and an env field which is an R environments, enclosed in the global environment. The value of the ID field is identical to the Tk window name. The env environment contains a parent variable and a num_subwin variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. .TkRoot is the top window with ID "."; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The parent variable is undefined for .TkRoot.

. Tk.ID extracts the ID of a window. . Tk.newwin creates a new window environment with a given ID and . Tk.subwin creates a new window which is a sub-window of a given parent window.

tkdestroy destroys a window and also removes the reference to a window from its parent.

is.tkwin can be used to test whether a given object is a window environment.

tclVar creates a new Tcl variable and initializes it to init. An R object of class tclVar is created to represent it. Using as.character on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the tclvalue function, which can also occur on the left-hand side of assignments. If tclvalue is passed an argument which is not a tclVar object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by tclVar are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

tclArray creates a new Tcl array and initializes it to the empty array. An R object of class tclArray and inheriting from class tclVar is created to represent it. You can access elements of the Tcl array using indexing with [[ or $, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index i refers to the element with the name as.character(i). Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for length and names, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl’s ‘dual-ported’ objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class tclObj. The string representation of such objects can be extracted (but not set) using tclvalue and conversion to vectors of mode "character", "double", "integer", "logical", and "raw" is performed using the standard coercion functions as.character, etc. Conversely, such vectors can be converted using as.tclObj. There is an ambiguity as to what should happen for length one vectors, controlled by the drop argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that tclvalue and as.character differ on an object whose string representation
has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a print method for `tclObj` objects; it prints `<Tcl>` followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the name of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class "tclObj" object if it succeeds, or FALSE if it fails (when a warning is issued). To see the current search path as an R character vector, use

```r
strsplit(tclvalue('auto_path'), " ")[1]
```

The Tcl version (including patchlevel) is returned as a character string (such as "8.6.3").

Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

See Also

`TkWidgets`, `TkCommands`, `TkWidgetcmds`. `capabilities("tcltk")` to see if Tcl/Tk support was compiled into this build of R.

Examples

tclVersion()

```r
## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
.Tcl("format \"%s\n\" \"Hello, World!\n\"")
f <- function()cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzy <- tclVar(7913)
tclvalue(xyzzy)
tclvalue(xyzzy) <- "foo"
as.character(xyzzy)
tcl("set", as.character(xyzzy))

top <- tktoplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all = TRUE)
ls(envir = .TkRoot$env, all = TRUE) # .Tcl.args put a callback ref in here

## End(Not run)
```
tclServiceMode | Allow Tcl events to be serviced or not

Description

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

Usage

tclServiceMode(on = NULL)

Arguments

on   (logical) Whether event servicing is turned on.

Details

If called with on == NULL (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

Value

The value of the Tcl service mode before the call.

Examples

## see demo(tkcanvas) for an example
## Not run:
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)

## End(Not run)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()

TkCommands | Tk non-widget commands

Description

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.
TkCommands

Usage

tcl(…)
tktitle(x)

tktitle(x) <- value
tkbell(…)
tkbind(…)
tkbindtags(…)

tkdialog(...)  
tkpopup(...)  

## File handling functions  
tclfile.tail(...)  
tclfile.dir(...)  
tclopen(...)  
tclclose(...)  
tclputs(...)  
tclread(...)  

Arguments

- **x**  
  A window object
- **value**  
  For tktitle assignments, a character string.
- **...**  
  Handled via .Tcl.args

Details

tcl provides a generic interface to calling any Tk or Tcl command by simply running .Tcl.args.objv on the argument list and passing the result to .Tcl.objv. Most of the other commands simply call tcl with a particular first argument and sometimes also a second argument giving the subcommand.

tktitle and its assignment form provides an alternate interface to Tk’s wm title

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like pack configure are converted to function names like tkpack.configure, and Tcl subcommands are like tclfile.dir.
See Also

TclInterface, TkWidgets, TkWidgetcmds

Examples

```r
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1 <- tklabel(tt, text = "Heave"), l2 <- tklabel(tt, text = "Ho"))
tkpack.configure(l1, side = "left")

## Try stretching the window and then

tkdestroy(tt)

## End(Not run)
```

tkpager

Page file using Tk text widget

Description

This plugs into file.show, showing files in separate windows.

Usage

```r
tkpager(file, header, title, delete.file)
```

Arguments

- **file**: character vector containing the names of the files to be displayed
- **header**: headers to use for each file
- **title**: common title to use for the window(s). Pasted together with the header to form actual window title.
- **delete.file**: logical. Should file(s) be deleted after display?

Note

The "\b_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

See Also

file.show
tkProgressBar

Progress Bars via Tk

Description

Put up a Tk progress bar widget.

Usage

```r
tkProgressBar(title = "R progress bar", label = ",
min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

Arguments

- `title, label` character strings, giving the window title and the label on the dialog box respectively.
- `min, max` (finite) numeric values for the extremes of the progress bar.
- `initial, value` initial or new value for the progress bar.
- `width` the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame).
- `pb, con` an object of class "tkProgressBar".
- `...` for consistency with the generic.

Details

`tkProgressBar` will display a widget containing a label and progress bar.

`setTkProgressBar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be closed when finished with.

This will use the ttk::progressbar widget for Tk version 8.5 or later, otherwise R’s copy of BWidget’s `progressbar`.

Value

For `tkProgressBar` an object of class "tkProgressBar".
For `getTkProgressBar` and `setTkProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTkProgressBar`).

See Also

`txtProgressBar`
Examples

```r
pb <- tkProgressBar("test progress bar", "Some information in %", 0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

**tkStartGUI**  
*Tcl/Tk GUI startup*

**Description**

Starts up the Tcl/Tk GUI

**Usage**

```r
tkStartGUI()
```

**Details**

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

**Note**

`tkStartGUI()` saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

tkscan.mark(widget, ...)

tkscan.dragto(widget, ...)
tksearch(widget, ...)
tksee(widget, ...)
tkselect(widget, ...)
tkselection.adjust(widget, ...)
tkselection.anchor(widget, ...)
tkselection.clear(widget, ...)
tkselection.from(widget, ...)
tkselection.includes(widget, ...)
tkselection.present(widget, ...)
tkselection.range(widget, ...)
tkselection.set(widget, ...)
tkselection.to(widget, ...)
tkset(widget, ...)
tksize(widget, ...)
tktoggle(widget, ...)
tktag.add(widget, ...)
tktag.bind(widget, ...)
tktag.cget(widget, ...)
tktag.configure(widget, ...)
tktag.delete(widget, ...)
tktag.lower(widget, ...)
tktag.names(widget, ...)
tktag.nextrange(widget, ...)
tktag.prevrange(widget, ...)
tktag.raise(widget, ...)
tktag.ranges(widget, ...)
tktag.remove(widget, ...)
tktype(widget, ...)
tkunpost(widget, ...)
tkwindow.cget(widget, ...)
tkwindow.configure(widget, ...)
tkwindow.create(widget, ...)
tkwindow.names(widget, ...)
tkxview(widget, ...)
tkxview.moveto(widget, ...)
tkxview.scroll(widget, ...)
tkyposition(widget, ...)
tkyview(widget, ...)
tkyview.moveto(widget, ...)
tkyview.scroll(widget, ...)

Arguments

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>widget</td>
<td>The widget this applies to</td>
</tr>
<tr>
<td>...</td>
<td>Handled via .Tcl.args</td>
</tr>
</tbody>
</table>

Details

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. Except for a few exceptions, the pattern is that Tcl widget commands possibly with subcommands like .a.b selection clear are converted to function names like tkselection.clear and the widget is given as the first argument.
TkWidgets

TclInterface, TkWidgets, TkCommands

Examples

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

# callback function
eval.txt <- function()
  eval(parse(text = tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:
tkdestroy(tt)

## End(Not run)

TkWidgets

Tk widgets

Description
Create Tk widgets and associated R objects.

Usage

tkwidget(parent, type, ...)
tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckbutton(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessagge(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)
ttkbutton(parent, ...)  
ttkcheckbutton(parent, ...)  
ttkcombobox(parent, ...)  
ttkframe(parent, ...)  
ttklabel(parent, ...)  
ttklabelframe(parent, ...)  
ttkmenubutton(parent, ...)  
ttknotebook(parent, ...)  
ttkpanedwindow(parent, ...)  
ttkprogressbar(parent, ...)  
ttkradiobutton(parent, ...)  
ttkscale(parent, ...)  
ttkscrollbar(parent, ...)  
ttkseparator(parent, ...)  
ttksizegrip(parent, ...)  
ttkspinbox(parent, ...)  
ttktreeview(parent, ...)  

Arguments

parent          Parent of widget window.
type            string describing the type of widget desired.
...             handled via .Tcl.args.

Details

These functions create Tk widgets. tkwidget creates a widget of a given type, the others simply call tkwidget with the respective type argument.

The functions starting ttk are for the themed widget set for Tk 8.5 or later. A tutorial can be found at http://www.tkdocs.com.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

Examples

## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

```r
tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
                          command = function()cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
    # see Tk-commands
```

## Push the button and then...
tk_choose.dir

## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  as.character(tcl("ttk::style", "theme", "names"))
  # select a theme -- here pre-XP windows
  tcl("ttk::style", "theme", "use", "winnative")
} else {
  # use Tk 8.0 widgets
}

## End(Not run)

---

**tk_choose.dir**

**Choose a Folder Interactively**

**Description**

Use a Tk widget to choose a directory interactively.

**Usage**

```r
tk_choose.dir(default = "", caption = "Select directory")
```

**Arguments**

- `default`: which directory to show initially.
- `caption`: the caption on the selection dialog.

**Value**

A length-one character vector, character NA if `Cancel` was selected.

**See Also**

- `tk_choose.files`

**Examples**

```r
## Not run:
tk_choose.dir(getwd(), "Choose a suitable folder")

## End(Not run)
```
choose.files  Choose a List of Files Interactively

**Description**

Use a Tk file dialog to choose a list of zero or more files interactively.

**Usage**

```r
tk_choose.files(default = "", caption = "Select files",
                multi = TRUE, filters = NULL, index = 1)
```

**Arguments**

- **default**: which filename to show initially.
- **caption**: the caption on the file selection dialog.
- **multi**: whether to allow multiple files to be selected.
- **filters**: two-column character matrix of filename filters.
- **index**: unused.

**Details**

Unlike `file.choose`, `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

**Value**

A character vector giving zero or more file paths.

**Note**

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

**See Also**

`file.choose`, `tk_choose.dir`

**Examples**

```r
Filters <- matrix(c("R code", ".R", "R code", ".s",
                   "Text", ".txt", "All files", "*"),
                   4, 2, byrow = TRUE)

if(interactive()) tk_choose.files(filter = Filters)
```
tk_messageBox  

Tk Message Box

Description
An implementation of a generic message box using Tk

Usage
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",  
"retrycancel", "aburtretrycancel"),  
message, caption = "", default = "", ...)

Arguments
- **type** character. The type of dialog box. It will have the buttons implied by its name.  
  Can be abbreviated.
- **message** character. The information field of the dialog box.
- **caption** the caption on the widget displayed.
- **default** character. The name of the button to be used as the default.
- **...** additional named arguments to be passed to the Tk function of this name. An example is icon = "warning".

Value
A character string giving the name of the button pressed.

See Also
tkmessageBox for a ‘raw’ interface.

---

tk_select.list  

Select Items from a List

Description
Select item(s) from a character vector using a Tk listbox.

Usage
tk_select.list(choices, preselect = NULL, multiple = FALSE,  
title = NULL)

Arguments
- **choices** a character vector of items.
- **preselect** a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- **multiple** logical: can more than one item be selected?
- **title** optional character string for window title, or NULL for no title.
Details

This is a version of `select.list` implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is modal, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

`select.list` (a text version except on Windows and the macOS GUI), `menu` (whose `graphics = TRUE` mode uses this on most Unix-alikes).
Chapter 13

The tools package

---

**tools-package** Tools for Package Development

**Description**
Tools for package development, administration and documentation.

**Details**
This package contains tools for manipulating R packages and their documentation. For a complete list of functions, use `library(help = "tools")`.

**Author(s)**
Kurt Hornik and Friedrich Leisch
Maintainer: R Core Team <R-core@r-project.org>

---

**.print.via.format** Printing Utilities

**Description**
`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```r
print.<myS3class> <- .print.via.format
```

**Usage**
`.print.via.format(x, ...)

**Arguments**
- `x` object to be printed.
- `...` optional further arguments, passed to `format`. 1731
Value

x, invisibly (by invisible()), as print methods should.

See Also

The print generic; its default method print.default (used for many basic implicit classes such as "numeric", "character" and arrays of them, lists etc).

Examples

## The function is simply defined as
function (x, ...) {
  writeLines(format(x, ...))
  invisible(x)
}

## is used for simple print methods in R, and as prototype for new methods.
assertCondition

Description

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

Usage

assertError(expr, verbose = FALSE)
assertWarning(expr, verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)

Arguments

expr an unevaluated R expression which will be evaluated via tryCatch(expr, ...).
... character strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.
.exprString The string to be printed corresponding to expr. By default, the actual expr will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If assertCondition() is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version.
verbose If TRUE, a message is printed when the condition is satisfied.

Details

assertCondition() uses the general condition mechanism to check all the conditions generated in evaluating expr. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

assertError() is a convenience function for asserting errors; it calls assertCondition().

assertWarning() asserts that a warning will be signalled, but not an error, whereas assertCondition(expr, "warning") will be satisfied even if an error follows the warning. See the examples.

Value

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See conditionMessage for the interpretation of these objects. Note that all conditions signalled during the evaluation are returned, whether or not they were among the requirements.

Author(s)

John Chambers and Martin Maechler
Select or Define a Bibliography Style

Description

This function defines and registers styles for rendering \texttt{bibentry} objects into ‘Rd’ format, for later conversion to text, HTML, etc.

Usage

\begin{verbatim}
bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)
\end{verbatim}
**bibstyle**

1735

**Arguments**

- **style**: A character string naming the style.
- **envir** (optional): An environment holding the functions to implement the style.
- **...**: Named arguments to add to the environment.
- **.init**: Whether to initialize the environment from the default style "JSS".
- **.default**: Whether to set the specified style as the default style.
- **all**: Whether to return the names of all registered styles.

**Details**

Rendering of **bibentry** objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the ‘jss.bst’ style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify `style` and some named entries via `...`. (Modifying the default "JSS" style is discouraged.) Setting `style` to `NULL` or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by **bibentry** as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`ed entry from the **bibentry** vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original **bibentry** vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named ".index" to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn’t use numbers, it includes a `fmtPrefix()` stub function that may be used to display them. See the example below.

**Value**

- `bibstyle` returns the environment which has been selected or created.
- `getBibstyle` returns the name of the default style, or all style names.

**Author(s)**

Duncan Murdoch

**See Also**

- `bibentry`
Examples

```r
refs <-
c(bibentry(bibtype = "manual",
    title = "R: A Language and Environment for Statistical Computing",
    author = person("R Core Team"),
    organization = "R Foundation for Statistical Computing",
    address = "Vienna, Austria",
    year = 2013,
    url = "https://www.R-project.org"),
bibentry(bibtype = "article",
    author = c(person(c("George", "E.", "P."), "Box"),
               person(c("David", "R."), "Cox"),
    year = 1964,
    title = "An Analysis of Transformations",
    journal = "Journal of the Royal Statistical Society, Series B",
    volume = 26,
    pages = "211-252"))

bibstyle("unsorted", sortKeys = function(refs) seq_along(refs),
        fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
        .init = TRUE)
print(refs, .bibstyle = "unsorted")
```

buildVignette Build One Vignette

Description

Run Sweave (or other custom weave function) texi2dvi, and/or Stangle (or other custom tangle function) on one vignette.

This is the workhorse of R CMD Sweave.

Usage

```r
buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE,
               quiet = TRUE, clean = TRUE, keep = character(),
               engine = NULL, buildPkg = NULL, encoding, ...)
```

Arguments

- **file**: character; the vignette source file
- **dir**: character; the working directory in which the intermediate and output files will be produced
- **weave**: logical; should weave be run?
- **latex**: logical; texi2pdf be run if weaving produces a `.tex` file?
- **tangle**: logical; should tangle be run?
- **quiet**: logical; run in quiet mode?
- **clean**: logical; whether to remove some newly created, often intermediate, files. See details below.
keep a list of file names to keep in any case when cleaning. Note that "target" files are kept anyway.

engine NULL or character; name of vignette engine to use. Overrides any \VignetteEngine{} markup in the vignette.

buildPkg NULL or character; an optional package in which to find the vignette engine.

encoding the encoding to assume for the file. If not specified, it will be inferred from the file contents.

... Additional arguments passed to weave and tangle.

Details

This function determines the vignette engine for the vignette (default utils::Sweave), then weaves and/or tangles the vignette using that engine. Finally, if clean is TRUE, newly created intermediate files (non "targets", where these depend on the engine, etc, and not any in keep) will be deleted. If clean is NA, and weave is true, newly created intermediate output files (e.g., `.tex`) will not be deleted even if a `.pdf` file has been produced from them.

If buildPkg is specified, it will be loaded before the vignette is processed, and will be used as the default package in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using \VignetteEngine{utils::Sweave} to specify the Sweave engine in the utils package) will override it. In contrast, if the engine argument is given, it will override the vignette source.

Value

A character vector naming the files that have been produced.

Author(s)

Henrik Bengtsson and Duncan Murdoch

See Also

buildVignettes for building all vignettes in a package.
Arguments

- **package**: a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory ‘doc’.
- **dir**: a character string specifying the path to a package’s root source directory. This subdirectory ‘vignettes’ (or if it does not exist ‘inst/doc’) is searched for vignette source files.
- **lib.loc**: a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known. The specified library trees are used to search for package.
- **quiet**: logical. Weave and run \texttt{texi2pdf} in quiet mode.
- **clean**: Remove all files generated by the build, even if there were copies there before.
- **tangle**: logical. Do tangling as well as weaving.
- **subdirs**: a character vector of subdirectories of \texttt{dir} in which to look for vignettes. The first which exists is used. Defaults to "doc" if \texttt{package} is supplied, otherwise "vignettes".
- **output**: logical indicating if the output filenames for each vignette should be returned (in component outputs).
- **source**: logical indicating if the tangled output filenames for each vignette should be returned (in component sources).
- **check**: logical. If \texttt{TRUE}, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines.

Details

\texttt{buildVignettes} is used by \texttt{R CMD build} and \texttt{R CMD check} to (re-)build vignette PDFs from their sources.

As of \texttt{R 3.4.1}, both of these functions ignore files that are listed in the ‘\.Rbuildignore’ file in \texttt{dir}.

Value

\texttt{buildVignettes} is called for its side effect of creating the PDF versions of all vignettes, and if \texttt{tangle = TRUE}, extracting the \texttt{R} code.

\texttt{pkgVignettes} returns an object of class “\texttt{pkgVignettes}” if a vignette directory is found, otherwise \texttt{NULL}.

Examples

```r
gVigns <- pkgVignettes("grid")
str(gVigns)
```
Description

charset_to_Unicode is a matrix of Unicode code points with columns for the common 8-bit encodings.

AdobeGlyphs is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

Usage

charset_to_Unicode
AdobeGlyphs

Details

charset_to_Unicode is an integer matrix of class c("noquote", "hexmode") so prints in hexadecimal. The mappings are those used by libiconv: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

AdobeGlyphs includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file ‘R_HOME/share/encodings/Adobe_glyphlist’.

Examples

## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.numeric(paste0("0x", Adobe Glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- AdobeGlyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")

Description

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as .C and .Fortran are called with a "NativeSymbolInfo" first argument or with argument PACKAGE specified, which is highly recommended to avoid name clashes in foreign function calls.
Usage

checkFF(package, dir, file, lib.loc = NULL,
registration = FALSE, check_DUP = FALSE,
verbose = getOption("verbose"))

Arguments

package a character string naming an installed package. If given, the installed R code of the package is checked.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectory ‘R’ (for R code). Only used if package is not given.
file the name of a file containing R code to be checked. Used if neither package nor dir are given.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
registration a logical. If TRUE, checks the registration information on the call (if available).
check_DUP a logical. If TRUE, .C and .Fortran calls with DUP = FALSE are reported.
verbose a logical. If TRUE, additional diagnostics are printed (and the result is returned invisibly).

Details

Note that we can only check if the name argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a useDynLib directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first useDynLib directive.

This checks that calls with PACKAGE specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the ‘DESCRIPTION’ file).

Value

An object of class "checkFF".

There are format and print methods to display the information contained in such objects.

See Also

.C, .Fortran; Foreign.

Examples

# order is pretty much random
checkFF(package = "stats", verbose = TRUE)
checkMD5sums  
Check and Create MD5 Checksum Files

Description
checkMD5sums checks the files against a file `MD5`.

Usage
checkMD5sums(package, dir)

Arguments
- package: the name of an installed package
- dir: the path to the top-level directory of an installed package.

Details
The file `MD5` which is created is in a format which can be checked by md5sum -c MD5 if a suitable command-line version of md5sum is available. (For Windows, one is supplied in the bundle at https://cran.r-project.org/bin/windows/Rtools.)

If dir is missing, an installed package of name package is searched for.

The private function tools:::.installMD5sums is used to create MD5 files in the Windows build.

Value
checkMD5sums returns a logical, NA if there is no `MD5` file to be checked.

See Also
md5sum

checkPoFiles  
Check Translation Files for Inconsistent Format Strings

Description
These functions compare formats embedded in English messages with translated strings to check for consistency. checkPoFile checks one file, while checkPoFiles checks all files for a specified language.

Usage
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
checkPoFiles

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
<td>a character string giving a single filepath.</td>
</tr>
<tr>
<td>strictPlural</td>
<td>whether to compare formats of singular and plural forms in a strict way.</td>
</tr>
<tr>
<td>language</td>
<td>a character string giving a language code.</td>
</tr>
<tr>
<td>dir</td>
<td>a path to a directory in which to check files.</td>
</tr>
</tbody>
</table>

Details

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R sprintf and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely c, u, p, n. It is allowed in C’s sprintf() function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the strictPlural argument is TRUE, then argument lists must agree exactly between singular and plural forms of messages; if FALSE, then translations only need to match one or the other of the two forms. When checkPoFiles calls checkPoFile, the strictPlural argument is set to TRUE for files with names starting ‘R-’, and to FALSE otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign ‘\uFF05’). Such signs will not be recognized as format specifiers, and are likely to be errors.

Value

Both functions return an object of S3 class “check_po_files”. A print method is defined for this class to display a report on the differences.

Author(s)

Duncan Murdoch

References

See the GNU gettext manual for the ‘.po’ file format:

update_pkg_po() which calls checkPoFile(); xgettext, sprintf.
**checkRd**

**Examples**

```r
## Not run:
checkPoFiles("de", "/path/to/R/src/directory")
## End(Not run)
```

**checkRd**

*Check an Rd Object*

**Description**

Check an help file or the output of the `parse_Rd` function.

**Usage**

```r
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
        unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

**Arguments**

- `Rd` a filename or Rd object to use as input.
- `defines` string(s) to use in #ifdef tests.
- `stages` at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
- `unknownOK` unrecognized macros are treated as errors if FALSE, otherwise warnings.
- `listOK` unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if FALSE, otherwise warnings.
- `...` additional parameters to pass to `parse_Rd` when Rd is a filename. One that is often useful is `encoding`.
- `def_enc` logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?

**Details**

`checkRd` performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the #ifdef and \Sexpr processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from `prepare_Rd` have level 0. These include:

- All text must be in a section
- Only one tag name section is allowed: the first will be used
- Section name is unrecognized and will be dropped
- Dropping empty section name
checkRd itself can show

- Tag *tag name* not recognized
- \tabular format must be simple text
- Unrecognized \tabular format: ... 
- Only *n* columns allowed in this table
- Must have a *tag name*
- Only one *tag name* is allowed
- Tag *tag name* must not be empty
- \docType must be plain text
- Tag \method is only valid in \usage
- Tag \dontrun is only valid in \examples
- Tag *tag name* is invalid in a block name block
- Title of \section must be non-empty plain text
- \title content must be plain text
- Empty section *tag name*
- Non-ASCII contents without declared encoding
- Non-ASCII contents in second part of \enc
- Tag ... is not valid in a code block
- Apparent non-ASCII contents without declared encoding
- Apparent non-ASCII contents in second part of \enc
- Unnecessary braces at ...
- \method not valid outside a code block

and variations with \method replaced by \S3method or \S4method.

Note that both prepare_Rd and checkRd have tests for an empty section: that in checkRd is stricter (essentially that nothing is output).

**Value**

This may fail through an R error, but otherwise warnings are collected as returned as an object of class "checkRd", a character vector of messages. This class has a print method which only prints unique messages, and has argument minlevel that can be used to select only more serious messages. (This is set to -1 in R CMD check.)

Possible fatal errors are those from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding) or from prepare_Rd (multiple \Rdversion declarations, invalid \encoding or \docType or \name sections, and missing or duplicate \name or \title sections).

**Author(s)**

Duncan Murdoch, Brian Ripley

**See Also**

parse_Rd, Rd2HTML.
checkRdaFiles

Report on Details of Saved Images or Re-saves them

Description
This reports for each of the files produced by save the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `.rda’ or `.RData’, hence the name of the function.

Usage
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
  compression_level, version = NULL)

Arguments
paths A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all `.rda’ and `.RData’ files in that directory.
compress, compression_level Type and level of compression: see save. Values of compress can be abbreviated.
version The format to be used when re-saving: see save.

Details
compress = "auto" asks R to choose the compression and ignores compression_level. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz” and choose the smallest compressed file (but with a 10% bias towards “gzip”). This can be slow.

For back-compatibility, version = NULL is interpreted to mean version 2: however version-3 files will only be saved as version 3.

Value
For checkRdaFiles, a data frame with rows names paths and columns
size numeric: file size in bytes, NA if the file does not exist.
ASCII logical: true for save(ASCII = TRUE), NA if the format is not that of an R save file.
compress character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an R save file it is from a later version of R).
version integer: the version of the save – usually 2 but 1 for very old files, and NA for other files. Unfortunately 2 means ‘version 2 or later’. 
checkTnF

Check R Packages or Code for T/F

Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

Usage

checkTnF(package, dir, file, lib.loc = NULL)

Arguments

package  a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.
dir  a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘R’ (for R code), and should also contain ‘man’ (for documentation). Only used if package is not given. If used, the R code files and the examples in the documentation files are checked.
file  the name of a file containing R code to be checked. Used if neither package nor dir are given.
lib.loc  a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.

Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a print method for nicely displaying the information contained in such objects.
checkVignettes

**Description**

Check all Sweave files of a package by running Sweave and/or Stangle on them. All R source code files found after the tangling step are sourceed to check whether all code can be executed without errors.

**Usage**

```r
checkVignettes(package, dir, lib.loc = NULL, 
tangle = TRUE, weave = TRUE, latex = FALSE, 
workdir = c("tmp", "src", "cur"), 
keepfiles = FALSE)
```

**Arguments**

- `package`: a character string naming an installed package. If given, Sweave files are searched in subdirectory `doc`.
- `dir`: a character string specifying the path to a package’s root source directory. This subdirectory `inst/doc` is searched for Sweave files.
- `lib.loc`: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for `package`.
- `tangle`: Perform a tangle and source the extracted code?
- `weave`: Perform a weave?
- `latex`: logical: if weave and latex are TRUE and there is no `Makefile` in the vignettes directory, run the weaved files through pdflatex.
- `workdir`: Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used.
- `keepfiles`: Delete files in the temporary directory? This option is ignored when workdir ! = "tmp".

**Details**

A ‘vignette’ is a file in the package’s ‘inst/doc’ directory with extension ‘.Rnw’ (preferred), ‘.Snw’, ‘.Rtex’ or ‘.Stex’ (and lower-case versions are also accepted).

If `tangle` is true, this function runs Stangle to produce (one or more) R code files from each vignette, then sources each code file in turn.

If `weave` is true, the vignettes are run through Sweave, which will produce a ‘.tex’ file for each vignette. If latex is also true, texi2pdf is run on the ‘.tex’ files from those vignettes which did not give errors in the previous steps.
An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a print method for displaying the information contained in such objects.

---

**check_packages_in_dir**  
*Check Source Packages and Their Reverse Dependencies*

**Description**

Check source packages in a given directory, optionally with their reverse dependencies.

**Usage**

```r
check_packages_in_dir(dir,  
  check_args = character(),  
  check_args_db = list(),  
  reverse = NULL,  
  check_env = character(),  
  xvfb = FALSE,  
  Ncpus = getOption("Ncpus", 1L),  
  clean = TRUE,  
  ...
)
```

```r
summarize_check_packages_in_dir_results(dir, all = TRUE,  
  full = FALSE)
```

```r
summarize_check_packages_in_dir_timings(dir, all = FALSE,  
  full = FALSE)
```

```r
summarize_check_packages_in_dir_depends(dir, all = FALSE,  
  which = c("Depends",  
    "Imports",  
    "LinkingTo"))
```

```r
check_packages_in_dir_changes(dir, old,  
  outputs = FALSE, sources = FALSE)
```

```r
check_packages_in_dir_details(dir, logs = NULL, drop_ok = TRUE)
```

**Arguments**

- **dir**: a character string giving the path to the directory with the source `.tar.gz` files to be checked.
- **check_args**: a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.
- **check_args_db**: a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.
- **reverse**: a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (default: `getOption("repos")`), the types of reverse dependencies (default: `c("Depends", "Imports", "LinkingTo")`), with shorthands "most" and...
check_packages_in_dir

"all" as for package_dependencies, and indicating whether to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked.

to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked.

to also summarize the reverse dependencies checked.

to also give details for checks with non-ok results, or summarize check example timings (if available).

to also investigate the changes in the source files checked (default: FALSE).

to analyze. Only used if dir was not given.

to drop checks with 'ok' status, or a character vector with the 'ok' status tags to drop. The default corresponds to tags 'OK', 'NONE' and 'SKIPPED'.

**Details**

check_packages_in_dir allows to conveniently check source package `.tar.gz` files in the given directory dir, along with their reverse dependencies as controlled by reverse.

The "which" component of reverse can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of reverse (which is recycled as needed).

If needed, the source `.tar.gz` files of the reverse dependencies to be checked as well are downloaded into dir (and removed at the end if clean is true). Next, all packages (additionally) needed for checking are installed to the 'Library' subdirectory of dir. Then, all `.tar.gz` files are checked using the given arguments and environment variables, with outputs and messages to files in the 'Outputs' subdirectory of dir. The '*Rcheck' directories with the check results of the reverse dependencies are renamed by prefixing their base names with 'rdepends'.

Results and timings can conveniently be summarized using summarize_check_packages_in_dir_results and summarize_check_packages_in_dir_timings, respectively.

Installation and checking is performed in parallel if Ncpus is greater than one: this will use mclapply on Unix and parLapply on Windows.
check_packages_in_dir returns an object inheriting from class "check_packages_in_dir" which has print and summary methods.

check_packages_in_dir_changes allows to analyze the effect of changing (some of) the sources. With dir and old the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options outputs and sources. The changes object returned can be subscripted according to change in severity from the old to the new results by using one of "==", "!="", "<", "<=", ">" or ">=" as row index.

check_packages_in_dir_details analyzes check log files to obtain check details as a data frame which can be used for further processing, providing check name, status and output for every check performed and not dropped according to status tag (via variables Check, Status and Output, respectively).

Environment variable _R_CHECK_ELAPSED_TIMEOUT_ can be used to set a limit on the elapsed time of each check run. See the ‘R Internals’ manual for how the value is interpreted and for other environment variables which can be used for finer-grained control on timeouts within a check run.

Note

This functionality is still experimental: interfaces may change in future versions.

Examples

## Not run:
## Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
## Check packages in dir and their reverse dependencies using the
## defaults (all repositories in getOption("repos"), all "strong"
## reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
## Check packages in dir with their reverse dependencies from CRAN,
## using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
    reverse = list(repos = getOption("repos")[%"CRAN"],
        which = "most"))
## Check packages in dir with their reverse dependencies from CRAN,
## using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
    check_args = c("--as-cran", ""),
    reverse = list(repos = getOption("repos")[%"CRAN"]))
## End(Not run)

codoc

Check Code/Documentation Consistency

desc

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. codoc compares names and optionally also corresponding positions and default values of the arguments of functions. codocClasses and codocData compare slot names of S4 classes and variable names of data sets, respectively.
Usage

codoc(package, dir, lib.loc = NULL,
     use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)

Arguments

package    a character string naming an installed package.
dir        a character string specifying the path to a package’s root source directory. This
            must contain the subdirectories ‘man’ with R documentation sources (in Rd
            format) and ‘R’ with R code. Only used if package is not given.
lib.loc    a character vector of directory names of R libraries, or NULL. The default value
            of NULL corresponds to all libraries currently known. The specified library trees
            are used to search for package.
use.values if FALSE, do not use function default values when comparing code and docs.
            Otherwise, compare all default values if TRUE, and only the ones documented in
            the usage otherwise (default).
verbose    a logical. If TRUE, additional diagnostics are printed.

Details

The purpose of codoc is to check whether the documented usage of function objects agrees with
their formal arguments as defined in the R code. This is not always straightforward, in particular
as the usage information for methods to generic functions often employs the name of the generic
rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the base
package), after possibly detaching an already loaded version of the package. Otherwise, if the
sources are used, the R code files of the package are collected and sourced in a new environment.
Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the
formals documented. For interpreted functions in the code environment, the formals are compared
between code and documentation according to the values of the argument use.values. Synopsis
sections are used if present; their occurrence is reported if verbose is true.

If a package has a namespace both exported and unexported objects are checked, as well as regis-
tered S3 methods. (In the unlikely event of differences the order is exported objects in the package,
registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes
and data sets (similar to the usage sections for function synopses). Variable names for data frames
in documentation objects obtained by suitably editing ‘templates’ created by prompt are recognized
by codocData and used provided that the documentation object is for a single data frame (i.e., only
has one alias). codocClasses analogously handles slot names for classes in documentation objects
obtained by editing shells created by promptClass.

Help files named ‘pkgname-defunct.Rd’ for the appropriate pkgname are checked more loosely,
as they may have undocumented arguments.

Value

codoc returns an object of class "codoc". Currently, this is a list which, for each Rd object in
the package where an inconsistency was found, contains an element with a list of the mismatches
compactPDF

(which in turn are lists with elements code and docs, giving the corresponding arguments obtained from the function’s code and documented usage).

codocClasses and codocData return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are print methods for nicely displaying the information contained in such objects.

Note

The default for use.values has been changed from FALSE to NULL, for R versions 1.9.0 and later.

undoc, QC

compactPDF

Compact PDF Files

Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.

Usage

compactPDF(paths, 
    qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
    gs_cmd = Sys.getenv("R_GSCMD", ""),
    gs_quality = Sys.getenv("GS_QUALITY", "none"),
    gs_extras = character())

## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)

Arguments

paths A character vector of paths to PDF files, or a length-one character vector naming a directory, when all '.pdf' files in that directory will be used.
qpdf Character string giving the path to the qpdf command. If empty, qpdf will not be used.
gs_cmd Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to 'gswin32c.exe' or 'gswin64c.exe'. If "" (the default), the function will try to find a platform-specific path to GhostScript where required.
gs_quality A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi). Can be abbreviated.
gs_extras An optional character vector of further options to be passed to GhostScript.
x An object of class "compactPDF".
ratio, diff Limits for reporting: files are only reported whose sizes are reduced both by a factor of ratio and by diff bytes.
... Further arguments to be passed to or from other methods.
Details

This by default makes use of qpdf, available from http://qpdf.sourceforge.net/ (including as a Windows binary) and included with the CRAN macOS distribution of R. If gs_cmd is non-empty and gs_quality != "none", GhostScript will used first, then qpdf if it is available. If gs_quality != "none" and gs_cmd is "", an attempt will be made to find a GhostScript executable.

qpdf and/or gs_cmd are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of qpdf is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX's pdflatex. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and qpdf are selected (when gs_quality != "none" and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

Value

An object of class c("compactPDF", "data.frame"). This has two columns, the old and new sizes in bytes for the files that were changed.

There are format and print methods: the latter passes ... to the format method, so will accept ratio and diff arguments.

Note

The external tools used may change in future releases.

Versions of GhostScript 9.06 and later give several times better compression than 9.05 on some vignettes in CRAN packages.

See Also

resaveRdaFiles.

Many other (and sometimes more effective) tools to compact PDF files are available, including Adobe Acrobat (not Reader). See the ‘Writing R Extensions’ manual.
Usage

CRAN_package_db()

CRAN_check_results(flavors = NULL)

CRAN_check_details(flavors = NULL)

CRAN_check_issues()

summarize_CRAN_check_status(packages,
                           results = NULL,
                           details = NULL,
                           issues = NULL)

Arguments

packages a character vector of package names.

flavors a character vector of CRAN check flavor names, or NULL (default), corresponding to all available flavors.

results the return value of CRAN_check_results() (default), or a subset of this.

details the return value of CRAN_check_details() (default), or a subset of this.

issues the return value of CRAN_check_issues() (default), or a subset of this.

Details

CRAN_package_db() returns a character data frame with most ‘DESCRIPTION’ metadata for the current packages in the CRAN package repository, including in particular the Description and Maintainer information not provided by utils::available.packages().

CRAN_check_results() returns a data frame with the basic CRAN package check results including timings, with columns Package, Flavor and Status giving the package name, check flavor, and overall check status, respectively.

CRAN_check_details() returns a data frame inheriting from class ‘check_details’ (which has useful print and format methods) with details on the check results, providing check name, status and output for every non-OK check (via columns Check, Status and Output, respectively). Packages with all-OK checks are indicated via a * Check wildcard name and OK Status.

CRAN_check_issues() returns a character frame with additional check issues (including the memory-access check results made available from https://www.stats.ox.ac.uk/pub/bdr/memtests/ and the without-long-double check results from https://www.stats.ox.ac.uk/pub/bdr/noLD), as a character frame with variables Package, Version, kind (an identifier for the issue) and href (a URL with information on the issue).

CRAN_memtest_notes() is now deprecated, with its functionality integrated into that of CRAN_check_issues().

Value

See ‘Details’. Note that the results are collated on CRAN: currently this is done in a locale which sorts aAbB ....

Which CRAN?

The main functions access a CRAN mirror specified by the environment variable R_CRAN_WEB, defaulting to one specified in the ‘repositories’ file (see setRepositories): if that specifies
@CRAN@ (the default) then https://CRAN.R-project.org is used. (Note that options("repos") is not consulted.)

Note that these access parts of CRAN under 'web/contrib' and 'web/packages' so if you have specified a mirror of just 'src/contrib' for installing packages you will need to set R_CRAN_WEB to point to a full mirror.

Examples

## This can be rather slow, especially with a non-local CRAN mirror
## and would fail (slowly) without Internet access in that case.

set.seed(11) # but the packages chosen will change as soon as CRAN does.
pdb <- CRAN_package_db()
dim(pdb)
## DESCRIPTION fields included:
colnames(pdb)
## Summarize publication dates:
summary(as.Date(pdb$Published))
## Summarize numbers of packages according to maintainer:
summary(lengths(split(pdb$Package, pdb$Maintainer)))
## Packages with 'LASSO' in their Description:
pdb$Package[grepl("LASSO", pdb$Description)]

results <- CRAN_check_results()
## Available variables:
names(results)
## Tabulate overall check status according to flavor:
with(results, table(Flavor, Status))

details <- CRAN_check_details()
## Available variables:
names(details)
## Tabulate checks according to their status:
tab <- with(details, table(Check, Status))
## Inspect some installation problems:
bad <- subset(details,
  ((Check == "whether package can be installed") &
   (Status != "OK")))
## Show a random sample of up to 6
head(bad[sample(seq_len(NROW(bad)), NROW(bad)), ])

issues <- CRAN_check_issues()
head(issues)
## Show counts of issues according to kind:
table(issues[, "kind"])

## Summarize CRAN check status for 10 randomly-selected packages
## (reusing the information already read in):
pos <- sample(seq_len(NROW(pdb)), 10L)
summarize_CRAN_check_status(pdb[pos, "Package"],
  results, details, issues)
dependsOnPkgs

Description

Find reverse dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

Usage

```
dependsOnPkgs(pkgs, 
  dependencies = c("Depends", "Imports", "LinkingTo"), 
  recursive = TRUE, lib.loc = NULL, 
  installed = 
    utils::installed.packages(lib.loc, fields = "Enhances"))
```
Arguments

pkgs
a character vector of package names.
dependencies
a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, and "most" currently shorthand for these apart from "Enhances".
recursive
logical: should reverse dependencies of reverse dependencies (and so on) be included?
lib.loc
a character vector of R library trees, or NULL for all known trees (see .libPaths).
installed
a result of calling installed.packages.

Value

A character vector of package names, which does not include any from pkgs.

Examples

## there are few dependencies in a vanilla R installation:
## lattice may not be installed
dependsOnPkgs("lattice")

encoded_text_to_latex  Translate non-ASCII Text to LaTeX Escapes

Description

Translate non-ASCII characters in text to LaTeX escape sequences.

Usage

encoded_text_to_latex(x, encoding = c("latin1", "latin2", "latin9", "UTF-8", "utf8"))

Arguments

x
a character vector.
encoding
the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's inputenc package.

Details

Non-ASCII characters in x are replaced by an appropriate LaTeX escape sequence, or ‘?’ if there is no appropriate sequence. Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to ‘\-’.

Value

A character vector of the same length as x.
fileutils

File Utilities

Description

Utilities for listing files, and manipulating file paths.

Examples

```r
x <- "fa\xE7ile"
encoded_text_to_latex(x, "latin1")
## Not run:
## create a tex file to show the upper half of 8-bit charsets
x <- rawToChar(as.raw(160:255), multiple = TRUE)
(x <- matrix(x, ncol = 16, byrow = TRUE))
xx <- x
xx[] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-encoding.tex", "w")
header <- c("\\documentclass{article}",
"\\usepackage[T1]{fontenc}",
"\\usepackage{Rd}",
"\\begin{document}",
"\\begin{Details}\relax",
"\\Tabular{cccccccccccccccc}{")
trailer <- c(""", "\\end{Details}", "\\end{document}"
writeLines(header, con)
writeLines(paste0(xx, \\", con)
writeLines(trailer, con)
close(con)
## End(Not run)
```

```
x <- intToUtf8(as.integer(
  c(160:383,0x0192,0x02C6,0x02C7,0x02CA,0x02D8,
    0x02D9, 0x02DD, 0x200C, 0x2018, 0x2019, 0x201C,
    0x201D, 0x2020, 0x2022, 0x2026, 0x20AC)),
multiple = TRUE)
x <- matrix(x, ncol = 16, byrow = TRUE)
xx <- x
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-utf8.tex", "w")
writeLines(header, con)
writeLines(paste(xx, "\\", sep = ""), con)
writeLines(trailer, con)
close(con)
## End(Not run)
```
Usage

file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
                      full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
                      full.names = TRUE, OS_subdirs = .OS_type())

Arguments

x character vector giving file paths.
compression logical: should compression extension ‘.gz’, ‘.bz2’ or ‘.xz’ be removed first?
dir a character string with the path name to a directory.
exts a character vector of possible file extensions (excluding the leading dot).
all.files a logical. If FALSE (default), only visible files are considered; if TRUE, all files are used.
full.names a logical indicating whether the full paths of the files found are returned (default), or just the file names.
type a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).
OS_subdirs a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable R_OSTYPE, or if this is empty, the value of .Platform$OS.type, is used.

Details

file_ext returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)
file_path_as_absolute turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for normalizePath. Currently, x must be a single existing path.
file_path_sans_ext returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)
list_files_with_exts returns the paths or names of the files in directory dir with extension matching one of the elements of exts. Note that by default, full paths are returned, and that only visible files are used.
list_files_with_type returns the paths of the files in dir of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of OS_subdirs. Note that by default, full paths are returned, and that only visible files are used.

See Also

file.path, file.info, list.files
find_gs_cmd

Examples

dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))

find_gs_cmd

Find a GhostScript Executable

Description

Find a GhostScript executable in a cross-platform way.

Usage

find_gs_cmd(gs_cmd = "")

Arguments

gs_cmd The name, full or partial path of a GhostScript executable.

Details

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called gs. The name (and possibly path) of
the command is taken first from argument gs_cmd then from the environment variable R_GSCMD and
default gs. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument gs_cmd then from the environment
variables R_GSCMD and GSC. If neither of those produces a suitable command name, gswin64c and
gswin32c are tried in turn. In all cases the command is looked for on the system PATH.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display
Postscript/PDF files and to manipulate them: this function looks for the latter.

Value

A character string giving the full path to a GhostScript executable if one was found, otherwise an
empty string.

Examples

## Not run:
## Suppose a Solaris system has GhostScript 9.00 on the path and
## 9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")
## End(Not run)
getVignetteInfo

Get Information on Installed Vignettes

Description

This function gets information on installed vignettes.

Usage

getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)

Arguments

package Which package to look in, or NULL for all packages.
lib.loc Which library to look in.
all Whether to search all installed packages, or just attached packages.

Value

A matrix with columns

<table>
<thead>
<tr>
<th>Package</th>
<th>the name of the package</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dir</td>
<td>the directory where the package is installed</td>
</tr>
<tr>
<td>Topic</td>
<td>the name of the vignette</td>
</tr>
<tr>
<td>File</td>
<td>the base filename of the source of the vignette</td>
</tr>
<tr>
<td>Title</td>
<td>the title of the vignette</td>
</tr>
<tr>
<td>R</td>
<td>the tangled R source from the vignette</td>
</tr>
<tr>
<td>PDF</td>
<td>the PDF or HTML file for display</td>
</tr>
</tbody>
</table>

Note

The last column of the result is named PDF for historical reasons, but it may contain a filename of a PDF or HTML document.

See Also

pkgVignettes is a similar function that can work on an uninstalled package.

Examples

getVignetteInfo("grid")
### HTMLheader

Generate a Standard HTML Header for R Help

**Description**

This function generates the standard HTML header used on R help pages.

**Usage**

```r
HTMLheader(title = "R", logo = TRUE, up = NULL,
  top = file.path(Rhome, "doc/html/index.html"),
  Rhome = ",
  css = file.path(Rhome, "doc/html/R.css"),
  headerTitle = paste("R:", title),
  outputEncoding = "UTF-8")
```

**Arguments**

- `title`: The title to display and use in the HTML headers. Should have had any HTML escaping already done.
- `logo`: Whether to display the R logo after the title.
- `up`: Which page (if any) to link to on the “up” button.
- `top`: Which page (if any) to link to on the “top” button.
- `Rhome`: A relative path to the R home directory. See the ‘Details’.
- `css`: The relative URL for the Cascading Style Sheet.
- `headerTitle`: The title used in the headers.
- `outputEncoding`: The declared encoding for the whole page.

**Details**

The up and top links should be relative to the current page. The Rhome path default works with dynamic help; for static help, a relative path (e.g., ‘../..’) to it should be used.

**Value**

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

**Examples**

```r
cat(HTMLheader("This is a sample header"), sep="\n")
```
HTMLlinks

HTMLlinks

1763

Collect HTML Links from Package Documentation

Description
Compute relative file paths for URLs to other package’s installed HTML documentation.
Usage
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
Arguments
pkgDir

the top-level directory of an installed package. The default indicates no package.

lib.loc

character vector describing the location of R library trees to scan: the default
indicates .libPaths().

level

Which level(s) to include.

Details
findHTMLlinks tries to resolve links from one help page to another. It uses in decreasing priority
• The package in pkgDir: this is used when converting HTML help for that package (level 0).
• The base and recommended packages (level 1).
• Other packages found in the library trees specified by lib.loc in the order of the trees and
alphabetically within a library tree (level 2).
Value
A named character vector of file paths, relative to the ‘html’ directory of an installed package. So
these are of the form ‘"../../somepkg/html/sometopic.html"’.
Author(s)
Duncan Murdoch, Brian Ripley

loadRdMacros

Load User-defined Rd Help System Macros

Description
Loads macros from an ‘.Rd’ file, or from several ‘.Rd’ files contained in a package.
Usage
loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros)


Arguments

file  A file in Rd format containing macro definitions.
macros TRUE or a previous set of macro definitions, in the format expected by the `parse_Rd` macros argument.
pkgdir The base directory of a source package or an installed package.

Details

The files parsed by this function should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The `macros` argument may be a filename of a base set of macros, or the result of a previous call to `loadRd Macros` or `loadPkgRd Macros` in the same session. These results should be assumed to be valid only within the current session.

The `loadPkgRd Macros` function first looks for an "Rd Macros" entry in the package 'DESCRIPTION' file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for `.Rd` files in the ‘man/macros’ or ‘help/macros’ subdirectories, and load those.

Value

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have `emptyenv()` as its parent.

`parse_Rd`

Examples

```r
f <- tempfile()
writeLines(paste0("\newcommand{\logo}{\if{html}{\figure{Rlogo.svg}{options: width=100}}, 
  "\if{latex}{\figure{Rlogo.pdf}{options: width=0.5in}}}"),
  f)

m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
```
**makevars**  
*User and Site Compilation Variables*

**Description**

Determine the location of the user and site specific 'Makevars' files for customizing package compilation.

**Usage**

```r
makevars_user()
makesvars_site()
```

**Details**

Package maintainers can use these functions to employ user and site specific compilation settings also for compilations not using R’s mechanisms (in particular, custom compilations in subdirectories of 'src'), e.g., by adding configure code calling R with `cat(tools::makevars_user())` or `cat(tools::makevars_site())`, and if non-empty passing this with `-f` to custom Make invocations.

**Value**

A character string with the path to the user or site specific 'Makevars' file, or an empty character vector if there is no such file.

**See Also**

Section “Customizing package compilation” in the “R Installation and Administration” manual.

**Examples**

```r
makevars_user()
makesvars_site()
```

---

**make_translations_pkg**  
*Package the Current Translations in the R Sources*

**Description**

A utility for R Core members to prepare a package of updated translations.

**Usage**

```r
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```
**Arguments**

- `srcdir` The R source directory.
- `outDir` The directory into which to place the prepared package.
- `append` The suffix for the package version number, e.g. 3.0.0-1 will be the default in R 3.0.0.

**Details**

This extracts the translations in a current R source distribution and packages them as a source package called `translations` which can be distributed on CRAN and installed by `update.packages`. This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘`Depends`’ field which restricts it to versions 3.x.* for a single x.

---

**md5sum**

*Compute MD5 Checksums*

**Description**

Compute the 32-byte MD5 hashes of one or more files.

**Usage**

`md5sum(files)`

**Arguments**

- `files` character. The paths of file(s) whose contents are to be hashed.

**Details**

A MD5 ‘hash’ or ‘checksum’ or ‘message digest’ is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different; only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the md5sum utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently modified.

**Value**

A character vector of the same length as `files`, with names equal to `files`. The elements will be `NA` for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

**Source**

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of glibc.

**See Also**

`checkMD5sums`
package_dependencies

Examples

as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))

package_dependencies  Computations on the Dependency Hierarchy of Packages

Description

Find (recursively) dependencies or reverse dependencies of packages.

Usage

package_dependencies(packages = NULL, db = NULL,
which = c("Depends", "Imports", "LinkingTo"),
recursive = FALSE, reverse = FALSE, verbose = getOption("verbose"))

Arguments

packages a character vector of package names.
db character matrix as from available.packages() (with the default NULL the results of this call) or data frame variants thereof. Alternatively, a package database like the one available from https://cran.r-project.org/web/packages/packages.rds.
which a character vector listing the types of dependencies, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances"). Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances".
recursive logical: should (reverse) dependencies of (reverse) dependencies (and so on) be included?
reverse logical: if FALSE (default), regular dependencies are calculated, otherwise reverse dependencies.
verbose logical indicating if output should monitor the package search cycles.

Value

Named list with one element for each package in argument packages, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the db, NULL entries are returned, as opposed to character(0) entries which indicate no dependencies.

See Also
dependsOnPkgs, and package.dependencies for checking dependencies.
Examples

```r
myPkgs <- c("MASS", "Matrix", "KernSmooth", "class", "cluster", "codetools")
pdb <- available.packages()

system.time(
  dep1 <- package_dependencies(myPkgs, db = pdb) # all arguments at default
) # very fast
utils::str(dep1, vec.len=10)

system.time(  # reverse dependencies, recursively --- takes much longer:
  deps <- package_dependencies(myPkgs, db = pdb,
    which = c("Depends", "Imports", "LinkingTo", "Suggests"),
    recursive = TRUE, reverse = TRUE)
) # seen ~ 10 seconds

lengths(deps) # 2015-01-14: all are 7040, but codetools with 7046
```

---

### package_native_routine_registration_skeleton

**Write Skeleton for Adding Native Routine Registration to a Package**

**Description**

Write a skeleton for adding native routine registration to a package.

**Usage**

```r
package_native_routine_registration_skeleton(dir, con = stdout(),
  align = TRUE, character_only = TRUE, include_declarations = TRUE)
```

**Arguments**

- `dir` Top-level directory of a package.
- `con` Connection on which to write the skeleton: can be specified as a file path.
- `align` Logical: should the registration tables be lined up in three columns each?
- `character_only` Logical: should only `.NAME` arguments specified by character strings (and not as names of R objects nor expressions) be extracted?
- `include_declarations` Logical: should the output include declarations (also known as ‘prototypes’) for the registered routines?

**Details**

Registration is described in section 5.4.1 of ‘Writing R Extensions’. This function produces a skeleton of the C code which needs to be added to enable registration, conventionally as file ‘src/init.c’ or appended to the sole C file of the package.

This function examines the code in the ‘R’ directory of the package for calls to `.C`, `.Fortran`, `.Call` and `.External and creates registration information for those it can make sense of. If the number of arguments used cannot be determined it will be recorded as `-1`: such values should be corrected.

Optionally the skeleton will include declarations for the registered routines: they should be checked against the C/Fortran source code, not least as the number of arguments is taken from the R code.
For `.Call` and `.External` calls they will often suffice, but for `.C` and `.Fortran` calls the void * arguments would ideally be replaced by the actual types. Otherwise declarations need to be included (they may exist earlier in that file if appending to a file, or in a header file which can be included in 'init.c').

The default value of `character_only` is appropriate when working on a package without any existing registration: `character_only = FALSE` can be used to suggest updates for a package which has been extended since registration. For the default value, if `.NAME` values are found which are not character strings (e.g. names or expressions) this is noted via a comment in the output.

Packages which used the earlier form of creating R objects for native symbols via additional arguments in a `useDynLib` directive will probably most easily be updated to use registration with `character_only = FALSE`.

If an entry point is used with different numbers of arguments in the package's R code, an entry in the table (and optionally, a declaration) is made for each number, and a comment placed in the output. This needs to be resolved: only `.External` calls can have a variable number of arguments, which should be declared as `-1`.

A surprising number of CRAN packages had calls in R code to native routines not included in the package, which will lead to a ‘loading failed’ error during package installation when the registration C code is added.

Calls which do not name a routine such as `.Call(...)` will be silently ignored.

**Value**

None: the output is written to the connection `con`.

**Extracting C/C++ prototypes**

There are several tools available to extract function declarations from C or C++ code. For example, for C code one can use cproto (http://invisible-island.net/cproto/cproto.html; Windows executables are available), for example

```
cproto -I/path/to/R/include -e *.c
```

`ctags` (commonly distributed with the OS) covers C and C++, listing all function usages by something like

```
ctags -x *.c
```

. (The ‘Exuberant’ version allows a lot more control.)

**Note**

This only examines the ‘R’ directory: it will not find e.g. `.Call` calls used directly in examples, tests etc.

Static code analysis is used to find the `.C` etc calls: it will find those in parts of the R code ‘commented out’ by inclusion in `if(FALSE) { ... }`. On the other hand, it will fail to find the entry points in constructs like

```
.Call(if(int) "rle_i" else "rle_d", i, force)
```
and does not know the value of variables in calls like

`.Call (cfunction, ...)`
`.Call(..., PACKAGE="sparseLTSEigen")`

(but if character_only is false, will extract the first as "cfunction"). Calls which have not been fully resolved will be noted via comments in the output file.

Call to entry points in other packages will be ignored if they have an explicit (character string) PACKAGE argument.

See Also

`package.skeleton`.

Examples

```r
## Not run:
## with a completed splines/DESCRIPTION file,
tools::package_native_routine_registration_skeleton('splines','','FALSE)
## produces
#include <R.h>
#include <Rinternals.h>
#include <stdlib.h> // for NULL
#include <R_ext/Rdynload.h>

/* FIXME:
Check these declarations against the C/Fortran source code.
*/

/* .Call calls */
extern SEXP spline_basis(SEXP, SEXP, SEXP, SEXP);
extern SEXP spline_value(SEXP, SEXP, SEXP, SEXP, SEXP);

static const R_CallMethodDef CallEntries[] = {
  {"spline_basis", (DL_FUNC) &spline_basis, 4},
  {"spline_value", (DL_FUNC) &spline_value, 5},
  (NULL, NULL, 8)
};

void R_init_splines(DllInfo *dll)
{
  R_registerRoutines(dll, NULL, CallEntries, NULL, NULL);
  R_useDynamicSymbols(dll, FALSE);
}
## End(Not run)
```

parseLatex

Experimental Functions to Work with LaTeX Code
parseLatex

Description
The parseLatex function parses LaTeX source, producing a structured object; deparseLatex reverses the process. The latexToUtf8 function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

Usage
parseLatex(text, filename = deparse(substitute(text)),
    verbose = FALSE,
    verbatim = c("verbatim", "verbatim*",
                  "Sinput", "Soutput"))
deparseLatex(x, dropBraces = FALSE)
llatexToUtf8(x)

Arguments
text A character vector containing LaTeX source code.
filename A filename to use in syntax error messages.
verbose If TRUE, print debug error messages.
verbatim A character vector containing the names of LaTeX environments holding verbatim text.
x A "LaTeX" object.
dropBraces Drop unnecessary braces when displaying a "LaTeX" object.

Details
The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in two forms: the \verb macro (with single character delimiters), and environments whose names are listed in the verbatim argument.

Value
The parseLatex() function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex_tag" attribute identifying its syntactic role.
The deparseLatex() function returns a single element character vector, possibly containing embedded newlines.
The latexToUtf8() function returns a modified version of the "LaTeX" object that was passed to it.

Author(s)
Duncan Murdoch

Examples
latex <- parseLatex("fa\c{c}ile")
deparseLatex(llatexToUtf8(latex))
parse_Rd

Parse an Rd File

Description
This function reads an R documentation (Rd) file and parses it, for processing by other functions.

Usage

```r
parse_Rd(file, srcfile = NULL, encoding = "unknown",
         verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
         macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
         permissive = FALSE)
```

Arguments

- `file` A filename or text-mode connection. At present filenames work best.
- `srcfile` NULL, or a "srcfile" object. See the 'Details' section.
- `encoding` Encoding to be assumed for input strings.
- `verbose` Logical indicating whether detailed parsing information should be printed.
- `fragment` Logical indicating whether file represents a complete Rd file, or a fragment.
- `warningCalls` Logical: should parser warnings include the call?
- `macros` Filename or environment from which to load additional macros, or a logical value. See the Details below.
- `permissive` Logical indicating that unrecognized macros should be treated as text with no warning.
- `x` An object of class Rd.
- `deparse` If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object.
- `...` Further arguments to be passed to or from other methods.

Details
This function parses ‘Rd’ files according to the specification given in [https://developer.r-project.org/parseRd.pdf](https://developer.r-project.org/parseRd.pdf).

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the encoding argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using ‘\newcommand’ or ‘\renewcommand’. An environment may also be given: it would be produced by `loadRdMacros`, `loadPkgRdMacros`, or by a previous call to `parse_Rd`. If a logical value is given, only the default
pskill

Kill a Process

Description

pskill sends a signal to a process, usually to terminate it.

Usage

pskill(pid, signal = SIGTERM)

SIGHUP
SIGINT
SIGQUIT
SIGKILL
SIGTERM
SIGSTOP
SIGTSTP
SIGCHLD
SIGUSR1
SIGUSR2
Arguments

- **pid**: positive integers: one or more process IDs as returned by `Sys.getpid`.
- **signal**: integer, most often one of the symbolic constants.

Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only `SIGINT` and `SIGTERM`). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, Ctrl-C sends `SIGINT`, Ctrl-\ sends `SIGQUIT` and Ctrl-Z sends `SIGTSTP`: that and `SIGSTOP` suspend a process which can be resumed by `SIGCONT`.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only `SIGINT` and `SIGKILL` will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

Value

A logical vector of the same length as `pid`, TRUE (for success) or FALSE, invisibly.

See Also

Package `parallel` has several means to launch child processes which record the process IDs.

Examples

```r
## Not run:
pskill(c(237, 245), SIGKILL)
## End(Not run)
```

`psnice` Get or Set the Priority (Niceness) of a Process

Description

Get or set the ‘niceness’ of the current process, or one or more other processes.

Usage

```r
psnice(pid = Sys.getpid(), value = NA_integer_)
```

Arguments

- **pid**: positive integers: the process IDs of one of more processes: defaults to the R session process.
- **value**: The niceness to be set, or NA for an enquiry.
Details

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as top report the priority and not the niceness. Niceness is used by the utility ‘/usr/bin/renice’: ‘/usr/bin/nice’ (and /usr/bin/renice -n) specifies an increment in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

Value

An integer vector of previous niceness values, NA if unknown for any reason.

See Also

Various functions in package parallel create child processes whose priority may need to be changed. pskill.

QC

QC Checks for R Code and/or Documentation

Description

Functions for performing various quality control (QC) checks on R code and documentation, notably on R packages.

Usage

checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)
/langElts
/nonS3methods(package)

Arguments

package a character string naming an installed package.
dir a character string specifying the path to a package’s root source directory. This should contain the subdirectories ‘R’ (for R code) and ‘man’ with R documentation sources (in Rd format). Only used if package is not given.
library a character vector of directory names of \texttt{R} libraries, or \texttt{NULL}. The default value of \texttt{NULL} corresponds to all libraries currently known. The specified library trees are used to search for package.

**Details**

\texttt{checkDocFiles} checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and ‘over-documented’ arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

\texttt{checkDocStyle} investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd \method markup for indicating S3 methods. Earlier versions of \texttt{R} also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With \method now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by \texttt{checkDocStyle}.)

\texttt{checkReplaceFuns} checks whether replacement functions or S3/S4 replacement methods in the package \texttt{R} code have their final argument named \texttt{value}.

\texttt{checkS3methods} checks whether all S3 methods defined in the package \texttt{R} code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions for the method. As an exception, the first argument of a formula method may be called \texttt{formula} even if this is not the name used by the generic. The rules when \ldots{} is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to \texttt{UseMethod} in their body, internal S3 generics (see \texttt{InternalMethods}), and S3 group generics (see \texttt{Math}). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the \texttt{base} package and (currently) the packages \texttt{graphics}, \texttt{stats}, and \texttt{utils} added in \texttt{R} 1.9.0 by splitting the former \texttt{base}, and, if an installed package is tested, also in the loaded namespaces/packages listed in the package’s ‘DESCRIPTION’ Depends field.

\texttt{nonS3methods(package)} returns a \texttt{character} vector with the names of the functions in package which ‘look’ like S3 methods, but are not. Using \texttt{package = NULL} returns all known examples.

\texttt{langElts} is a character vector of names of “language elements” of \texttt{R}. These are implemented as “very primitive” functions (no argument list; \texttt{print()}ing as \texttt{Primitive("<name>")}).

If using an installed package, the checks needing access to all \texttt{R} objects of the package will load the package (unless it is the \texttt{base} package), after possibly detaching an already loaded version of the package.

**Value**

The functions return objects of class the same as the respective function names containing the information about problems detected. There are \texttt{print} methods for nicely displaying the information contained in such objects.

---

**Rcmd**

*R CMD Interface*

**Description**

Invoke \texttt{R CMD} tools from within \texttt{R}.
Usage

Rcmd(args, ...)  

Arguments

args a character vector of arguments to R CMD.  
... arguments to be passed to system2.

Details

Provides a portable convenience interface to the R CMD mechanism by invoking the corresponding system commands (using the version of R currently used) via system2.

Value

See section “Value” in system2.

Rd2HTML

Rd Converters

Description

These functions take the output of the parse_Rd function and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

Usage

Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,  
        Links = NULL, Links2 = NULL,  
        stages = "render", outputEncoding = "UTF-8",  
        dynamic = FALSE, no_links = FALSE, fragment = FALSE,  
        stylesheet = "R.css", ...)  

Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,  
       stages = "render", outputEncoding = "",  
       fragment = FALSE, options, ...)  

Rd2latex(Rd, out = "", defines = .Platform$OS.type,  
         stages = "render", outputEncoding = "ASCII",  
         fragment = FALSE, ..., writeEncoding = TRUE)  

Rd2ex(Rd, out = "", defines = .Platform$OS.type,  
      stages = "render", outputEncoding = "UTF-8",  
      commentDontrun = TRUE, commentDonttest = FALSE, ...)  

Arguments

Rd a filename or Rd object to use as input.  
out a filename or connection object to which to write the output.  
package the package to list in the output.
defines string(s) to use in #ifdef tests.
stages at which stage ("build", "install", or "render") should \Sexpr macros be executed? See the notes below.
outputEncoding see the ‘Encodings’ section below.
dynamic logical: set links for render-time resolution by dynamic help system.
no_links logical: suppress hyperlinks to other help topics. Used by R CMD Rdconv.
fragment logical: should fragments of Rd files be accepted? See the notes below.
stylesheet character: a URL for a stylesheet to be used in the header of the HTML output page.
Links, Links2 NULL or a named (by topics) character vector of links, as returned by findHTMLlinks.
options An optional named list of options to pass to Rd2txt_options.
... additional parameters to pass to parse_Rd when Rd is a filename.
writeEncoding should \inputencoding lines be written in the file for non-ASCII encodings?
commentDontrun should \dontrun sections be commented out?
commentDonttest should \donttest sections be commented out?

Details

These functions convert help documents: Rd2HTML produces HTML, Rd2txt produces plain text, Rd2latex produces LaTeX. Rd2ex extracts the examples in the format used by example and R utilities.

Each of the functions accepts a filename for an Rd file, and will use parse_Rd to parse it before applying the conversions or checks.

The difference between arguments Link and Link2 is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Note that the default for Rd2latex is to output ASCII, including using the second option of \enc markup. This was chosen because use of UTF-8 in LaTeX requires version ‘2005/12/01’ or later, and even with that version the coverage of UTF-8 glyphs is not extensive (and not even as complete as Latin-1).

Rd2txt will format text paragraphs to a width determined by width, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

Rd2txt will use directional quotes (see sQuote) if option "useFancyQuotes" is true (the default) and the current encoding is UTF-8.

Various aspects of formatting by Rd2txt are controlled by the options argument, documented with the Rd2txt_options function. Changes made using options are temporary, those made with Rd2txt_options are persistent.

When fragment = TRUE, the Rd file will be rendered with no processing of \Sexpr elements or conditional defines using #ifdef or ifndef. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For Rd2latex, the output name is given an attribute "latexEncoding" giving the encoding of the file in a form suitable for use with the LaTeX ‘inputenc’ package.
Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in
the encoding of non-ASCII characters. In general, any such encoding should be declared using the
‘encoding’ section for there to be any hope of correct rendering.

For output, the outputEncoding argument will be used: outputEncoding = "" will choose the
native encoding for the current system.

If the text cannot be converted to the outputEncoding, byte substitution will be used (see iconv):
Rd2latex and Rd2ex give a warning.

Note

The \Sexpr macro is a new addition to Rd files. It includes R code that will be executed at one of
three times: build time (when a package's source code is built into a tarball), install time (when
the package is installed or built into a binary package), and render time (when the man page is
converted to a readable format).

For example, this man page was:
1. built on 2018-02-23 at 02:33:07,
2. installed on 2018-02-23 at 02:33:07, and
3. rendered on 2018-02-23 at 02:36:15.

Examples

## Not run:
## Simulate install and rendering of this page in HTML and text format:

Rd <- file.path("src/library/tools/man/Rd2HTML.Rd")

outfile <- tempfile(fileext = ".html")
browseURL(Rd2HTML(Rd, outfile, package = "tools",
stages = c("install", "render")))

outfile <- tempfile(fileext = ".txt")
file.show(Rd2txt(Rd, outfile, package = "tools",
stages = c("install", "render")))

checkRd(Rd) # A stricter test than Rd2HTML uses

## End(Not run)
Rd2txt_options  

Set Formatting Options for Text Help

Description

This function sets various options for displaying text help.

Usage

Rd2txt_options(...)

Arguments

...  

A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

Details

This function persistently sets various formatting options for the Rd2txt function which is used in displaying text format help. Currently defined options are:

width  (default 80): The width of the output page.

minIndent  (default 10): The minimum indent to use in a list.

extraIndent  (default 4): The extra indent to use in each level of nested lists.

sectionIndent  (default 5): The indent level for a section.

sectionExtra  (default 2): The extra indentation for each nested section level.

itemBullet  (default "* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.

text

enumFormat : A function to format item numbers in enumerated lists.

text

text

text

text

text

text

text

text

text

text

text

text

text

text

text

Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

# The itemBullet is locale-specific
saveOpts <- Rd2txt_options()
saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()
Rd2txt_options(saveOpts)
Rd2txt_options()
```

---

**Rdiff**

**Difference R Output Files**

**Description**

Given two R output files, compute differences ignoring headers, footers and some other differences.

**Usage**

```r
Rdiff(from, to, useDiff = FALSE, forEx = FALSE, nullPointers = TRUE, Log = FALSE)
```

**Arguments**

- `from, to` - filepaths to be compared
- `useDiff` - should diff always be used to compare results?
- `forEx` - logical: extra pruning for `--Ex.Rout` files to exclude the header.
- `nullPointers` - logical: should the displayed addresses of pointers be set to `0x00000000` before comparison?
- `Log` - logical: should the returned value include a log of differences found?

**Details**

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see `sQuote`) and on Windows, Windows' so-called 'smart quotes', are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., `<environment: 0x12345678>`) are mapped to `0x00000000`. The files are then compared line-by-line. If there are the same number of lines and `useDiff` is false, a simple `diff -b`-like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise `diff -bw` is called on the edited files. (This tries to ignore all differences in whitespace: note that flag `-w` is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions.)

This can compare uncompressed PDF files, ignoring differences in creation and modification dates. Mainly for use in examples, text from marker `'> ## IGNORE_RDIFF_BEGIN` up to (but not including) `'> ## IGNORE_RDIFF_END` is ignored.

**Value**

If `Log` is true, a list with components `status` (see below) and `out`, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator, `0L` if and only if no differences were found.
RdTextFilter

Select Text in an Rd File

Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

Usage

RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
    drop = character(), keep = character(),
    macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))

Rdindex

Generate Index from Rd Files

Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

Usage

Rdindex(RdFiles, outFile = "", type = NULL,
    width = 0.9 * getOption("width"), indent = NULL)

Arguments

RdFiles a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.

outFile a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.

type a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the \docType tag; if type is "data", Rd files whose only keyword is datasets are included as well.

width a positive integer giving the target column for wrapping lines in the output.

indent a positive integer specifying the indentation of the second column. Must not be greater than width/2, and defaults to width/3.

Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

See Also

The shell script run as \ R CMD Rdiff.

RdTextFilter

Select Text in an Rd File

Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

Usage

RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,
    drop = character(), keep = character(),
    macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))
Arguments

ifile  
An input file specified as a filename or connection, or an "Rd" object from parse_Rd.

encoding  
An encoding name to pass to parse_Rd.

keepSpacing  
Whether to try to leave the text in the same lines and columns as in the original file.

drop  
Additional sections of the Rd to drop.

keep  
Sections of the Rd file to keep.

macros  
Macro definitions to assume when parsing. See parse_Rd.

Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as aspell can check only the text and report the position in the original file. (If keepSpacing is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags \S3method, \S4method, \command, \docType, \email, \encoding, \file, \key-word, \link, \linkS4class, \method, \pkg, and \var are skipped. Additional tags can be skipped by listing them in the drop argument; listing tags in the keep argument will stop them from being skipped. It is also possible to keep any of the c("RCODE", "COMMENT", "VERB") tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

aspell, for which this is an acceptable filter.
Rdutils

Rd Utilities

Description

Utilities for computing on the information in Rd objects.

Usage

Rd_db(package, dir, lib.loc = NULL)

Arguments

package      a character string naming an installed package.
dir          a character string specifying the path to a package’s root source directory. This
             should contain the subdirectory ‘man’ with R documentation sources (in Rd
             format). Only used if package is not given.
lib.loc      a character vector of directory names of R libraries, or NULL. The default value
             of NULL corresponds to all libraries currently known. The specified library trees
             are used to search for package.

Details

Rd_db builds a simple database of all Rd objects in a package, as a list of the results of running
parse_Rd on the Rd source files in the package and processing platform conditionals.

See Also

parse_Rd

Examples

## Build the Rd db for the (installed) base package.
db <- Rd_db("base")
## Keyword metadata per Rd object.
keywords <- lapply(db, tools::Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1:5]
## The "most informative" ones:
kw_table[kw_table == 1]
## Concept metadata per Rd file.
concepts <- lapply(db, tools::Rd_get_metadata, "concept")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
**read.00Index**  
*Read 00Index-style Files*

**Description**  
Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

**Usage**

```
read.00Index(file)
```

**Arguments**

- `file`  
  the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, `file` can be a connection, which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

**See Also**

- `formatDL` for the inverse operation of creating a 00Index-style file from items and their descriptions.

**showNonASCII**  
*Pick Out Non-ASCII Characters*

**Description**  
This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

**Usage**

```
showNonASCII(x)
showNonASCII(file)
```

**Arguments**

- `x`  
  a character vector.
- `file`  
  path to a file.
**Details**

This was originally written to help detect non-portable text in files in packages.

It prints all element of x which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted via `iconv(sub = "byte")`.

**Value**

The elements of x containing non-ASCII characters will be returned invisibly.

**Examples**

```r
out <- c(
"fa\xE7ile test of showNonASCII():",
"\details{
" This is a good line",
" This has an \xfcmlaut in it.",
" OK again.",
"})

f <- tempfile()
cat(out, file = f, sep = "\n")
showNonASCIIfile(f)
unlink(f)
```

**Description**

This function starts the internal help server, so that HTML help pages are rendered when requested.

**Usage**

```r
startDynamicHelp(start = TRUE)
```

**Arguments**

- `start` logical: whether to start or shut down the dynamic help system. If NA, the server is started if not already running.

**Details**

This function starts the internal HTTP server, which runs on the loopback interface (127.0.0.1). If `options("help.ports")` is set to a vector of non-zero integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value or `options("help.ports")` to 0.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.
If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for 127.0.0.1.

**Value**

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

**See Also**

`help.start` and `help(help_type = "html")` will attempt to start the HTTP server if required.

`Rd2HTML` is used to render the package help pages.

---

### `SweaveTeXFilter` (Strip R Code out of Sweave File)

**Description**

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

**Usage**

```r
SweaveTeXFilter(ifile, encoding = "unknown")
```

**Arguments**

- `ifile`: Input file or connection.
- `encoding`: Text encoding to pass to `readLines`.

**Details**

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

**Author(s)**

Duncan Murdoch

**See Also**

`aspell`, for which this is used with `filter = "Sweave"`. 
testInstalledPackage  Test Installed Packages

Description

These functions allow an installed package to be tested, or all base and recommended packages.

Usage

\[
\begin{align*}
testInstalledPackage & \quad \text{pkg, lib.loc = NULL, outDir = ".", types = c("examples", "tests", "vignettes"), srcdir = NULL, Ropts = "", ...} \\
testInstalledPackages & \quad \text{outDir = ".", errorsAreFatal = TRUE, scope = c("both", "base", "recommended"), types = c("examples", "tests", "vignettes"), srcdir = NULL, Ropts = "", ...} \\
testInstalledBasic & \quad \text{scope = c("basic", "devel", "both", "internet")}
\end{align*}
\]

Arguments

- **pkg** name of an installed package.
- **lib.loc** library path(s) in which to look for the package. See `library`.
- **outDir** the directory into which to write the output files: this should already exist.
- **types** type(s) of tests to be done.
- **errorsAreFatal** logical: should testing terminate at the first error?
- **srcdir** Optional directory to look for .save files.
- **Ropts** Additional options such as `-d valgrind` to be passed to `R CMD BATCH` when running examples or tests.
- **...** additional arguments use when preparing the files to be run, e.g. `commentDontrun` and `commentDonttest`.
- **scope** Which set(s) should be tested? Can be abbreviated.

Details

These tests depend on having the package example files installed (which is the default). If package-specific tests are found in a `tests` directory they can be tested: these are not installed by default, but will be if `R CMD INSTALL --install-tests` was used. Finally, the `R` code in any vignettes can be extracted and tested.

Package tests are run in a `pkg-tests` subdirectory of `outDir`, and leave their output there.

`testInstalledBasic` runs the basic tests, if installed. This should be run with `LC_COLLATE=C` set: the function tries to set this by it may not work on all OSes. For non-English locales it may be desirable to set environment variables `LANGUAGE` to `en` and `LC_TIME` to `C` to reduce the number of differences from reference results.

Except on Windows, if the environment variable `TEST_MC_CORES` is set to an integer greater than one, `testInstalledPackages` will run the package tests in parallel using its value as the maximum number of parallel processes.
The package-specific tests for the base and recommended packages are not normally installed, but `make install-tests` is provided to do so (as well as the basic tests).

**Value**

Invisibly 0L for success, 1L for failure.

### texi2dvi

**Compile LaTeX Files**

**Description**

Run `latex/pdflatex`, `makeindex` and `bibtex` until all cross-references are resolved to create a dvi or a PDF file.

**Usage**

```r
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
texi2pdf(file, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

**Arguments**

- **file** character string. Name of the LaTeX source file.
- **pdf** logical. If TRUE, a PDF file is produced instead of the default dvi file (texi2dvi command line option `--pdf`).
- **clean** logical. If TRUE, all auxiliary files created during the conversion are removed.
- **quiet** logical. No output unless an error occurs.
- **texi2dvi** character string (or NULL). Script or program used to compile a TeX file to dvi or PDF. The default (selected by "" or "texi2dvi" or NULL) is to look for a program or script named `texi2dvi` on the path and otherwise emulate the script with `system2` calls (which can be selected by the value "emulation"). See also 'Details'.
- **texinputs** NULL or a character vector of paths to add to the LaTeX and bibtex input search paths.
- **index** logical: should indices be prepared?

**Details**

`texi2pdf` is a wrapper for the common case of `texi2dvi(pdf = TRUE)`.

Despite the name, this is used in R to compile LaTeX files, specifically those generated from vignettes and by the `Rd2pdf` script (used for package reference manuals). It ensures that the `R_HOME/share/texmf` directory is in the TEXINPUTS path, so R style files such as ‘Sweave’ and ‘Rd’ will be found. The TeX search path used is first the existing TEXINPUTS setting (or the current directory if unset), then elements of argument texinputs, then `R_HOME/share/texmf` and finally the default path. Analogous changes are made to BIBINPUTS and BSTINPUTS settings.
The default option for \texttt{texi2dvi} is set from environment variable $\texttt{R_TEXI2DVICMD}$, and the default for that is set from environment variable $\texttt{TEXI2DVI}$ or if that is unset, from a value chosen when R is configured.

A shell script \texttt{texi2dvi} is part of GNU's \texttt{texinfo}. Several issues have been seen with released versions, so if yours does not work correctly try $\texttt{R_TEXI2DVICMD=emulation}$.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the \texttt{hyperref} LaTeX package) even on valid input. The argument $\texttt{index = FALSE}$ is provided to allow package manuals to be made when this happens: it uses emulation.

\textbf{Value}

Invisible \texttt{NULL}. Used for the side effect of creating a dvi or PDF file in the current working directory (and maybe other files, especially if $\texttt{clean = FALSE}$).

\textbf{Note}

There are various versions of the \texttt{texi2dvi} script on Unix-alikes and quite a number of bugs have been seen, some of which this R wrapper works around.

One that was present with \texttt{texi2dvi} version 4.8 (as supplied by macOS) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike \texttt{texi2dvi} script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (\texttt{texi2dvi} 5.0 and later; \texttt{texify.exe} from MiKTeX), option \texttt{--max-iterations=20} is used to avoid infinite retries.

The emulation mode supports $\texttt{quiet = TRUE}$ from R 3.2.3 only. Currently $\texttt{clean = TRUE}$ only cleans up in this mode if the conversion was successful—this gives users a chance to examine log files in the event of error.

All the approaches should respect the values of environment variables \texttt{LATEX}, \texttt{PDFLATEX}, \texttt{MAKEINDEX} and \texttt{BIBTEX} for the full paths to the corresponding commands.

\textbf{Author(s)}

Originally Achim Zeileis but largely rewritten by R-core.

---

\textbf{toHTML}

\textit{Display an Object in HTML}

\textbf{Description}

This generic function generates a complete HTML page from an object.

\textbf{Usage}

\begin{verbatim}
toHTML(x, ...)
## S3 method for class 'packageIQR'
toHTML(x, ...)
## S3 method for class 'news_db'
toHTML(x, ...)
\end{verbatim}
Arguments

x  An object to display.
...

Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to HTMLheader.

Value

A character vector to display the object x. The "packageIQR" method is designed to display lists in the \text{R} help system.

See Also

HTMLheader

Examples

cat(toHTML(demo(package = "base")), sep = "\n")

tools-deprecated  Deprecated Objects in Package tools

Description

The functions or variables listed here are provided for compatibility with older versions of \text{R} only, and may be defunct as soon as of the next release.

Usage

package.dependencies(x, check = FALSE, depLevel = c("Depends", "Imports", "Suggests"))

gDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE, lib.loc = NULL)

installFoundDepends(depPkgList, ...)

Arguments

x  A matrix of package descriptions as returned by available.packages.
check  If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies.
depLevel  Whether to look for Depends or Suggests level dependencies. Can be abbreviated.
depMtrx  a dependency matrix as from package.dependencies().
pkg  the name of the package
instPkgs  a matrix specifying all packages installed on the local system, as from installed.packages
Recursive whether or not to include indirect dependencies.
local whether or not to search only locally
reduce whether or not to collapse all sets of dependencies to a minimal value
lib.loc what libraries to use when looking for installed packages. NULL indicates all library directories in the current .libPaths(). Note that lib.loc is not used in getDepList() and deprecated there.
depPkgList A found element from a pkgDependsList object
... Arguments to pass on to install.packages

See Also

Deprecated, Defunct

toRd

Generic Function to Convert Object to a Fragment of Rd Code

Description

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

Usage

toRd(obj, ...)
## S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)

Arguments

obj The object to be rendered.
style The style to be used in converting a bibentry object.
... Additional arguments used by methods.

Details

See bibstyle for a discussion of styles. The default style = NULL value gives the default style.

Value

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts obj to mode character, then escapes any Rd markup within it. The bibentry method converts an object of that class to markup appropriate for use in a bibliography.
### toTitleCase

**Convert Titles to Title Case**

**Description**

Convert a character vector to title case, especially package titles.

**Usage**

`toTitleCase(text)`

**Arguments**

- `text`  
a character vector.

**Details**

This is intended for English text only.

No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.

Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

**Value**

A character vector of the same length as `text`, without names.

---

### undoc

**Find Undocumented Objects**

**Description**

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

**Usage**

`undoc(package, dir, lib.loc = NULL)`

**Arguments**

- `package`  
a character string naming an installed package.
- `dir`  
a character string specifying the path to a package’s root source directory. This must contain the subdirectory ‘man’ with R documentation sources (in Rd format), and at least one of the ‘R’ or ‘data’ subdirectories with R code or data objects, respectively.
- `lib.loc`  
a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for `package`. 
Details

This function is useful for package maintainers mostly. In principle, all user-level \texttt{R} objects should be documented.

The \texttt{base} package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments \texttt{.ArgsEnv} and \texttt{.GenericArgsEnv} in the \texttt{base} package that are used for various purposes: \texttt{undoc("base")} checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a print method for nicely displaying the information contained in such objects.

See Also

codoc, QC

Examples

\begin{verbatim}
undoc("tools") # Undocumented objects in 'tools'
\end{verbatim}

update_pkg_po

\textit{Prepare Translations for a Package}

\textbf{Description}

Prepare the ‘po’ directory of a package and compile and install the translations.

\textbf{Usage}

\begin{verbatim}
update_pkg_po(pkgdir, pkg = NULL, version = NULL, copyright, bugs)
\end{verbatim}

\textbf{Arguments}

\begin{itemize}
  \item \texttt{pkgdir} The path to the package directory.
  \item \texttt{pkg} The package name: if NULL it is read from the package’s ‘DESCRIPTION’ file.
  \item \texttt{version} The package version: if NULL it is read from the package’s ‘DESCRIPTION’ file.
  \item \texttt{copyright, bugs} optional character strings for the 'Copyright' and 'Report-Msgid-Bugs-To' details in the template files.
\end{itemize}

\textbf{Details}

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a ‘po’ directory, one is created.
- \texttt{xgettext2pot} is called to create/update a file ‘po/R-pkgname.pot’ containing the translatable messages in the package.
• All existing files in directory po with names ‘R-lang.po’ are updated from ‘R-pkgname.pot’, checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.

• In a UTF-8 locale, a ‘translation’ ‘R-en@quot.po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

• The remaining steps are done only if file ‘po/pkname.pot’ already exists. The ‘src/*.{c,cc,cpp,m,mm}’ files in the package are examined to create a file ‘po/pkname.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.

• All existing files in directory po with names ‘lang.po’ are updated from ‘pkgname.pot’, checkPoFile is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.

• In a UTF-8 locale, a ‘translation’ ‘en@quot.po’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file ‘po/pkname.pot’ in the package sources and run this function again.

pkg = “base” is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

System requirements

This function requires the following tools from the GNU gettext-tools: xgettext, msgmerge, msgfmt, msginit and msgconv. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including macOS). Pre-compiled versions for Windows are available in https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip.

It will probably not work correctly for en@quot translations except in a UTF-8 locale, so these are skipped elsewhere.

See Also

xgettext2pot.
vignetteEngine

Arguments

vignette The path to the vignette source
recursive Whether or not to include indirect dependencies
reduce Whether or not to collapse all sets of dependencies to a minimal value
local Whether or not to search only locally
lib.loc What libraries to search in locally

Details

If recursive is TRUE, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If recursive is FALSE, only the dependencies directly named by the vignette will be used.

If local is TRUE, the system will only look at the user’s local machine and not online to find dependencies.

If reduce is TRUE, the system will collapse the fields in the DependsList object such that a minimal set of dependencies are specified (for instance if there was ‘foo, foo (>= 1.0.0), foo (>= 1.3.0), it would only return ‘foo (>= 1.3.0)’).

Value

An object of class “DependsList”.

vignetteEngine 

Set or Get a Vignette Processing Engine

Description

Vignettes are normally processed by Sweave, but package writers may choose to use a different engine (e.g., one provided by the knitr, noweb or R.rsp packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

Usage

vignetteEngine(name, weave, tangle, pattern = NULL, package = NULL, aspell = list())
Arguments

name  
weave  
tangle  
pattern  
package  
aspell  

Details

If weave is missing, vignetteEngine will return the currently registered engine matching name and package.

If weave is NULL, the specified engine will be deleted.

Other settings define a new engine. The weave and tangle functions must be defined with argument lists compatible with `function(file, ...)`. Currently the `...` arguments may include logical argument quiet and character argument encoding; others may be added in future. These are described in the documentation for Sweave and Stangle.

The weave and tangle functions should return the filename of the output file that has been produced. Currently the weave function, when operating on a file named `<name> <pattern>` must produce a file named `<name>.[.]tex|pdf|html`. The `.tex` files will be processed by pdflatex to produce `.pdf` output for display to the user; the others will be displayed as produced. The tangle function must produce a file named `<name>.[.]rRsS` containing the executable R code from the vignette. The tangle function may support a `split = TRUE` argument, and then it should produce files named `<name>.*[.]rRsS`.

The pattern argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to NULL, the default pattern "[.]\\[RrSs\\](nw|tex)$" is used.

Value

If the engine is being deleted, NULL. Otherwise a list containing components

name  
package  
pattern  
weave  
tangle  

Author(s)

Duncan Murdoch and Henrik Bengtsson.

Examples

str(vignetteEngine("Sweave"))

write_PACKAGES

Generate PACKAGES Files

Description

Generate ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files for a repository of source or Mac/Windows binary packages.

Usage

write_PACKAGES(dir = ".", fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
               latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz")

Arguments

dir Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files from and write them to.

fields a character vector giving the fields to be used in the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files in addition to the default ones, or NULL (default).

The default corresponds to the fields needed by available.packages: "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if addFile = TRUE and the path to the subdirectory in field "Path" if subdirectories are used.

type Type of packages: currently source ‘.tar.{gz,bz2,xz}’ archives, and macOS or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.

verbose logical. Should packages be listed as they are processed?

unpacked a logical indicating whether the package contents are available in unpacked form or not (default).

subdirs either logical (to indicate if subdirectories should be included, recursively) or a character vector of names of subdirectories to include (which are not recursed).

latestOnly logical: if multiple versions of a package are available should only the latest version be included?

addFiles logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.

rds_compress The type of compression to be used for ‘PACKAGES.rds’: see saveRDS. The default is the one found to give maximal compression, and is as used on CRAN.
Details

write_PACKAGES scans the named directory for R packages, extracts information from each package's 'DESCRIPTION' file, and writes this information into the 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files, where the first two represent the information in DCF format, and the third serializes it via `saveRDS`.

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example `latestOnly = FALSE` could be used for a source repository when 'foo_1.0' depends on 'R >= 2.15.0' but 'foo_0.9' is available which depends on 'R >= 2.11.0'.

Support for repositories with subdirectories and hence for `subdirs != FALSE` depends on recording a "Path" field in the 'PACKAGES' files.

Support for more general file names (e.g., other types of compression) via a "File" field in the 'PACKAGES' files can be used by `download.packages`. If the file names are not of the standard form, use `addFiles = TRUE`.

type = "win.binary" uses `unz` connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory dir, and builds files 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files from this information.

For a remote repository there is a tradeoff between download speed and time spent by `available.packages` processing the downloaded file(s). For large repositories it is likely to be beneficial to use `rds_compress = "xz"`.

Value

Invisibly returns the number of packages described in the resulting 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files. If 0, no packages were found and no files were written.

Note

Processing '.tar.gz' archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.

Author(s)

Uwe Ligges and R-core.

See Also

See `read.dcf` and `write.dcf` for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files.

Examples

```r
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
              type = "win.binary") # on Linux

## End(Not run)
```
xgettext  Extract Translatable Messages from R Files in a Package

Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to `stop`, `warning`, `message`, `gettext` and `gettextf`, or to `ngettext`.

Usage

```r
xgettext(dir, verbose = FALSE, asCall = TRUE)
```

```r
xngettext(dir, verbose = FALSE)
```

```r
xgettext2pot(dir, potFile, name = "R", version, bugs)
```

Arguments

- `dir`  the directory of a source package.
- `verbose`  logical: should each file be listed as it is processed?
- `asCall`  logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.
- `potFile`  name of po template file to be produced. Defaults to ‘R-pkgname.pot’ where `pkgname` is the basename of ‘dir’.
- `name`, `version`, `bugs`  as recorded in the template file: version defaults the version number of the currently running R, and bugs to "bugs.r-project.org".

Details

Leading and trailing white space (space, tab and linefeed) is removed for calls to `gettext`, `gettextf`, `stop`, `warning`, and `message`, as it is by the internal code that passes strings for translation.

We look to see if these functions were called with `domain = NA` and if so omit the call if `asCall = TRUE`: note that the call might contain a call to `gettext` which would be visible if `asCall = FALSE`.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file for use with the GNU Gettext tools. This ensures that the strings for simple translation are unique in the file (as GNU Gettext requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual, but `msgfmt` complains if there is duplication between the sets.).

If applied to the `base` package, this also looks in the ‘.R’ files in ‘`R_HOME/share/R’.”

Value

For `xgettext`, a list of objects of class "xgettext" (which has a `print` method), one per source file that potentially contains translatable strings.

For `xngettext`, a list of objects of class "xngettext", which are themselves lists of length-2 character strings.
See Also

update_pkg_po() which calls xgettext2pot().

Examples

## Not run: ## in a source-directory build of R:
xgettext(file.path(R.home(), "src", "library", "splines"))

adist Approximate String Distances

Description
Compute the approximate string distance between character vectors. The distance is a generalized
Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions
and substitutions needed to transform one string into another.

Usage
adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,
    partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
Arguments

- **x**: a character vector. **Long vectors** are not supported.
- **y**: a character vector, or **NULL** (default) indicating taking x as y.
- **costs**: a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or **NULL** (default) indicating using unit cost for all three possible transformations.
- **counts**: a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the "counts" attribute of the return value.
- **fixed**: a logical. If **TRUE** (default), the x elements are used as string literals. Otherwise, they are taken as regular expressions and **partial = TRUE** is implied (corresponding to the approximate string distance used by **agrep** with **fixed = FALSE**).
- **partial**: a logical indicating whether the transformed x elements must exactly match the complete y elements, or only substrings of these. The latter corresponds to the approximate string distance used by **agrep** (by default).
- **ignore.case**: a logical. If **TRUE**, case is ignored for computing the distances.
- **useBytes**: a logical. If **TRUE** distance computations are done byte-by-byte rather than character-by-character.

Details

The (generalized) Levenshtein (or edit) distance between two strings s and t is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform s into t (so that the transformation exactly matches t). This distance is computed for **partial = FALSE**, currently using a dynamic programming algorithm (see, e.g., [https://en.wikipedia.org/wiki/Levenshtein_distance](https://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity $O(mn)$, where m and n are the lengths of s and t, respectively. Additionally computing the transformation sequence and counts is $O(\max(m,n))$.

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of t with minimal distance to the pattern s (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [https://en.wikipedia.org/wiki/Approximate_string_matching](https://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for **partial = TRUE** using ‘tre’ by Ville Laurikari ([http://laurikari.net/tre/](http://laurikari.net/tre/)) and corresponds to the distance used by **agrep**. In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between s and t can be different from the distance between t and s.

Value

A matrix with the approximate string distances of the elements of x and y, with rows and columns corresponding to x and y, respectively.

If **counts** is **TRUE**, the transformation counts are returned as the "counts" attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of x, the elements of y, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if **partial = FALSE**, the transformation sequences are returned as the "trafos" attribute of the return value, as character strings with elements 'M', 'I', 'D' and 'S' indicating a match, insertion, deletion and substitution, respectively. If **partial = TRUE**, the offsets (positions of the first and last element) of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets $-1$ in case of no match).
See Also

agrep for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

Examples

```r
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```
apropos

Find Objects by (Partial) Name

Description

apropos() returns a character vector giving the names of objects in the search list matching (as a regular expression) what.

find() returns where objects of a given name can be found.

Usage

apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")

find(what, mode = "any", numeric = FALSE, simple.words = TRUE)

Arguments

what character string. For simple.words = FALSE the name of an object; otherwise a regular expression to match object names against.

where, numeric a logical indicating whether positions in the search list should also be returned

ignore.case logical indicating if the search should be case-insensitive, TRUE by default.

mode character; if not "any", only objects whose mode equals mode are searched.

simple.words logical; if TRUE, the what argument is only searched as a whole word.

Details

If mode != "any" only those objects which are of mode mode are considered.

find is a different user interface for a similar task to apropos. By default (simple.words == TRUE), only whole names are matched. Unlike apropos, matching is always case-sensitive.

Unlike the default behaviour of ls, names which begin with a '.' are included (and these are often 'internal' objects — as from R 3.4.0 most such are excluded).

Value

For apropos, a character vector sorted by name. For where = TRUE this has names giving the (numerical) positions on the search path.

For find, either a character vector of environment names or (for numeric = TRUE) a numerical vector of positions on the search path with names the names of the corresponding environments.

Author(s)

Originally, Kurt Hornik and Martin Maechler (May 1997).

See Also

glob2rx to convert wildcard patterns to regular expressions.

# the 8-and-more letter things
apropos("^.{8,}\$")
table(nchar(apropos("^.{8,}\$"))))

---

aregexec

Approximate String Match Positions

Description

Determine positions of approximate string matches.

Usage

aregexec(pattern, text, max.distance = 0.1, costs = NULL,
  ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)

Arguments

pattern a non-empty character string or a character string containing a regular expression
  (for fixed = FALSE) to be matched. Coerced by as.character to a string if possible.
text  character vector where matches are sought. Coerced by as.character to a character vector if possible.
max.distance  maximum distance allowed for a match. See agrep.
costs  cost of transformations. See agrep.
ignore.case  a logical. If TRUE, case is ignored for computing the distances.
fixed  If TRUE, the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.
useBytes  a logical. If TRUE comparisons are byte-by-byte rather than character-by-character.

Details
aregexec provides a different interface to approximate string matching than agrep (along the lines of the interfaces to exact string matching provided by regexec and grep).
Note that by default, agrep performs literal matches, whereas aregexec performs regular expression matches.
See agrep and adist for more information about approximate string matching and distances.
Comparisons are byte-by-byte if pattern or any element of text is marked as "bytes".

Value
A list of the same length as text, each element of which is either −1 if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of pattern, with attribute "match.length" an integer vector giving the lengths of the matches (or −1 for no match).

See Also
regmatches for extracting the matched substrings.

Examples
### Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)

askYesNo  Ask a Yes/No Question

Description
askYesNo provides a standard way to ask the user a yes/no question. It provides a way for front-ends to substitute their own dialogs.
Usage

```
askYesNo(msg, default = TRUE,
    prompts = getOption("askYesNo", gettext(c("Yes", "No", "Cancel"))),
    ...)
```

Arguments

- `msg`: The prompt message for the user.
- `default`: The default response.
- `prompts`: Any of: a character vector containing 3 prompts corresponding to return values of TRUE, FALSE, or NA, or a single character value containing the prompts separated by / characters, or a function to call.
- `...`: Additional parameters, ignored by the default function.

Details

`askYesNo` will accept case-independent partial matches to the prompts. If no response is given the value of `default` will be returned; if a non-empty string that doesn’t match any of the prompts is entered, an error will be raised.

If a function or single character string naming a function is given for `prompts`, it will be called as `fn(msg = msg, default = default, prompts = prompts, ...)`. On Windows, the GUI uses the unexported `utils:::askYesNoWinDialog` function for this purpose.

If strings (or a string such as "Y/N/C") are given as `prompts`, the choices will be mapped to lowercase for the non-default choices, and left as-is for the default choice.

Value

`TRUE` for yes, `FALSE` for no, and `NA` for cancel.

See Also

`readline` for more general user input.

Examples

```
if (interactive())
    askYesNo("Do you want to use askYesNo?")
```

aspell

**Spell Check Interface**

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

```
aspell(files, filter, control = list(), encoding = "unknown",
      program = NULL, dictionaries = character())
```
Arguments

files
a character vector with the names of files to be checked.

filter
an optional filter for processing the files before spell checking, given as either a function (with formals ifile and encoding), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See Details for available filters. If missing or NULL, no filtering is performed.

control
a list or character vector of control options for the spell checker.

encoding
the encoding of the files. Recycled as needed.

program
a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.

dictionaries
a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory ‘share/dictionaries’ of the R home directory). The file extension (currently, only ‘.rds’) can be omitted.

Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See http://aspell.net, http://hunspell.sourceforge.net/ and http://lasr.cs.ucla.edu/geoff/ispell.html, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

The currently available built-in filters are "Rd" (corresponding to RdTextFilter), "Sweave" (corresponding to SweaveTeXFilter), "R", "pot", "dcf" and "md".

Filter "R" is for R code and extracts the message string constants in calls to message, warning, stop, packageStartupMessage, gettext, gettextf, and ngettext (the unnamed string constants for the first five, and fmt and msg1/msg2 string constants, respectively, for the latter two).

Filter "pot" is for message string catalog ‘.pot’ files. Both have an argument ignore allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using "^[ \	]*[^\^]^[ \t]:punct:]" ignores all text inside single quotes.

Filter "dcf" is for files in Debian Control File format. The fields to keep can be controlled by argument keep (a character vector with the respective field names). By default, ‘Title’ and ‘Description’ fields are kept.

Filter "md" is for files in Markdown format (‘.md’ and ‘.Rmd’ files), and needs packages commonmark and xml2 to be available.

The print method for the objects returned by aspell has an indent argument controlling the indentation of the positions of possibly mis-spelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in grep-mode. It also has a verbose argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension ‘.rds’ obtained by serializing character vectors of word lists using saveRDS. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘-p’): hence, the default personal dictionary is not used in this case.
Value

A data frame inheriting from aspell (which has a useful print method) with the information about possibly mis-spelled words.

aspell-utils for utilities for spell checking packages.

Package Aspell on Omegahat (http://www.omegahat.net/Aspell) for a fine-grained R interface to the Aspell library.

Examples

## Not run:
## To check all Rd files in a directory, (additionally) skipping the 
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.swn"))
aspell(files, filter = "Sweave", control = "--t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))

aspell-utils

Spell Check Utilities

Description

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

Usage

aspell_package_Rd_files(dir, drop = c("\author", "\references"),
control = list(), program = NULL,
dictionaries = character())
aspell_package_vignettes(dir,
control = list(), program = NULL,
dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
program = NULL,
dictionaries = character())
ASPell-UTILS

```r
program = NULL, dictionaries = character()
aspell_package_C_files(dir, ignore = character(), control = list(),
  program = NULL, dictionaries = character())

aspell_write_personal_dictionary_file(x, out, language = "en",
  program = NULL)
```

**Arguments**

- `dir` a character string specifying the path to a package’s root directory.
- `drop` a character vector naming additional Rd sections to drop when selecting text via `RdTextFilter`.
- `control` a list or character vector of control options for the spell checker.
- `program` a character string giving the name (if on the system path) or full path of the spell check program to be used, or `NULL` (default). By default, the system path is searched for `aspell`, `hunspell` and `ispell` (in that order), and the first one found is used.
- `dictionaries` a character vector of names or file paths of additional R level dictionaries to use. See `aspell`.
- `ignore` a character vector with regular expressions to be replaced by blanks when filtering the message strings.
- `x` a character vector, or the result of a call to `aspell()`.
- `out` a character string naming the personal dictionary file to write to.
- `language` a character string indicating a language as used by Aspell.

**Details**

Functions `aspell_package_Rd_files`, `aspell_package_vignettes`, `aspell_package_R_files` and `aspell_package_C_files` perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory `dir`. They determine the respective files, apply the appropriate filters, and run the spell checker.

See `aspell` for details on filters.

The C-level message string are obtained from the ‘po/PACKAGE.pot’ message catalog file, with `PACKAGE` the basename of `dir`. See the section on “C-level messages” in “Writing R Extensions” for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citep`, `\code`, `\pkg`, `\proglang` and `\samp`. Further commands can be skipped by adding `--add-tex-command` options to the control argument. E.g., to skip both option and parameter of `\mycmd`, add `--add-tex-command=\mycmd op`.

Suitable values for `control`, `program`, `dictionaries`, `drop` and `ignore` can also be specified using a package defaults file which should go as ‘defaults.R’ into the ‘.aspell’ subdirectory of `dir`, and provides defaults via assignments of suitable named lists, e.g.,

```r
vignettes <- list(control = "--add-tex-command=\mycmd op")
```

for vignettes (when using Aspell) and similarly assigning to `Rd_files`, `R_files` and `C_files` for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options `--master=en_US` and `--add-extra-dicts=en_GB` to Aspell and control options `--d en_US, en_GB` to Hunspell (provided that the corresponding dictionaries are installed).
available.packages

Older versions of R had no support for R level dictionaries, and hence provided the function `aspell_write_personal_dictionary_file` to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `.rds` files obtained by serializing character vectors of such words using `saveRDS`. For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `.aspell` subdirectory.

`aspell`

available.packages  List Available Packages at CRAN-like Repositories

Description

available.packages returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

Usage

```r
available.packages(contriburl = contrib.url(repos, type), method,
fields = NULL, type = getOption("pkgType"),
filters = NULL, repos = getOption("repos"),
ignore_repo_cache = FALSE, max_repo_cache_age,
...)
```

Arguments

- `contriburl` URL(s) of the `contrib` sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you burned only the `contrib` section on a CD.
- `method` download method, see `download.file`.
- `type` character string, indicate which type of packages: see `install.packages`. If type = “both” this will use the source repository.
- `fields` a character vector giving the fields to extract from the `PACKAGES` file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.
- `filters` a character vector or list or NULL (default). See ‘Details’.
- `repos` character vector, the base URL(s) of the repositories to use.
- `ignore_repo_cache` logical. If true, the repository cache is never used (see ‘Details’).
- `max_repo_cache_age` any cached values older than this in seconds will be ignored. See ‘Details’.
- `...` allow additional arguments to be passed from callers (which might be arguments to future versions of this function).
available.packages

Details

The list of packages is either copied from a local mirror (specified by a ‘file://’ URI) or downloaded. If downloaded and ignore_repo_cache is false (the default), the list is cached for the R session in a per-repository file in `tempdir()` with a name like

repos_http%3a%2f%2fcran.r-project.org%2fsrsrc%2fcontrib.rds

The cached values are renewed when found to be too old, with the age limit controlled via argument max_repo_cache_age. This defaults to the current value of the environment variable R AVAILABLE PACKAGES CACHE CONTROL MAX AGE, or if unset, to 3600 (one hour).

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument filters can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`: this value corresponds to `getOption("available_packages_filters")` and to c("R_version", "OS_type", "subarch", "duplicates") if that is unset or set to NULL.

The built-in filters are

"R_version" Exclude packages whose R version requirements are not met.

"OS_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and vice versa.

"subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in `contriburl`) with the latest version if that is in more than one repository.

"license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., https://en.wikipedia.org/wiki/FOSS) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be known to be FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.

"CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied before the default "duplicates" filter, so cannot be used with add = TRUE.

If all the filters are from this set, then they can be specified as a character vector; otherwise filters should be a list with elements which are character strings, user-defined functions or add = TRUE (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by `available.packages`, and return a matrix consisting of a subset of the rows of the argument.

The special ‘filter’ add = TRUE appends the other elements of the filter list to the default filters.

Value

A matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "CRAN", "R_version", "OS_type", "subarch", and "license/FOSS", "license/restricts_use".
"Enhances", "File" and "Repository". Additional columns can be specified using the fields argument.

Where provided by the repository, fields "OS_type", "License", "License_is_FOSS", "License_restricts_use", "Archs", "MD5sum" and "NeedsCompilation" are reported for use by the filters and package management tools, including `install.packages`.

See Also

install.packages, download.packages, contrib.url.

The 'R Installation and Administration' manual for how to set up a repository.

Examples

```r
## Not run:
## Restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
## or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))

## Give priority to released versions on CRAN, rather than development
## versions on Omegahat, R-Forge etc.
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))
## End(Not run)
```

## Batch Execution of R

**Description**

Run R non-interactively with input from `infile` and send output (stdout/stderr) to another file.

**Usage**

```r
R CMD BATCH [options] infile [outfile]
```

**Arguments**

- `infile`: the name of a file with R code to be executed.
- `options`: a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If `infile` starts with a `-`, use `--` as the final option. The default options are `--restore --save --no-readline`. (Without `--no-readline` on Windows.)
- `outfile`: the name of a file to which to write output. If not given, the name used is that of `infile`, with a possible ".R" extension stripped, and ".Rout" appended.
Details

Use R CMD BATCH --help to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add options(echo = FALSE) at the beginning of infile, or use option '--slave'.

The infile can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression 'proc.time()' will be executed after the input script unless the latter calls q(runLast = FALSE) or is aborted. This can be suppressed by the option '--no-timing'.

Additional options can be set by the environment variable R_BATCH_OPTIONS: these come after the default options (see the description of the options argument) and before any options given on the command line.

Note

Unlike Splus BATCH on a Unix-alike, this does not run the R process in the background. In most shells,

R CMD BATCH [options] infile [outfile] &

will do so.

bibentry

Bibliography Entries

Description

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

Usage

bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
  key = NULL, ..., other = list(),
  mheader = NULL, mfooter = NULL)

## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle, ...)

## S3 method for class 'bibentry'
format(x, style = "text", .bibstyle = NULL,
  citation.bibtex.max = getOption("citation.bibtex.max", 1),
  bibtex = length(x) <= citation.bibtex.max,
  sort = FALSE, macros = NULL, ...)

## S3 method for class 'bibentry'
sort(x, decreasing = FALSE, .bibstyle = NULL, drop = FALSE, ...)

## S3 method for class 'citation'
print(x, style = "citation", ...)

## S3 method for class 'citation'
format(x, style = "citation", ...)
Arguments

- **bibtype**: a character string with a BibTeX entry type. See **Entry Types** for details.
- **textVersion**: a character string with a text representation of the reference to optionally be employed for printing. It is recommended to leave this unspecified if `format(x, style = "text")` works correctly. Only if special LaTeX macros (e.g., math formatting) or special characters (e.g., with accents) are necessary, a `textVersion` should be provided.
- **header**: a character string with optional header text.
- **footer**: a character string with optional footer text.
- **key**: a character string giving the citation key for the entry.
- **...**: for `bibentry`: arguments of the form `tag=value` giving the fields of the entry, with `tag` and `value` the name and value of the field, respectively. Arguments with empty values are dropped. See **Entry Fields** for details.
- **other**: a list of arguments as in `...` (useful in particular for fields named the same as formals of `bibentry`).
- **mheader**: a character string with optional “outer” header text.
- **mfooter**: a character string with optional “outer” footer text.
- **x**: an object inheriting from class `"bibentry"`.
- **style**: an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see **Details**.
- **decreasing**: logical, passed to `order` indicating the sort direction.
- **.bibstyle**: a character string naming a bibliography style.
- **citation.bibtex.max**: (deprecated, use `bibtex = T|F` instead!) a number, say `m`, indicating that the bibtex code should be given in addition to the formatted `tex` when there are not more than `m` entries. The default is taken as `getOption("citation.bibtex.max", 1)` which is 1 typically. For example, to see no bibtex at all, you can change the default by `options(citation.bibtex.max = 0)`.
- **bibtex**: logical indicating if bibtex code should be given additionally; currently applies only to `style = "citation"`. The default depends on on the number of (bib) entries and `getOption("citation.bibtex.max")`.
- **sort**: logical indicating if `bibentries` should be sorted, using `bibstyle(.bibstyle)$sortKeys(x)`.
- **macros**: a character string or an object with already loaded Rd macros, see **Details**.
- **drop**: logical used as `x[, ... , drop=drop]` inside the `sort()` method.

Details

The `bibentry` objects created by `bibentry` can represent an arbitrary positive number of references. One can use `c()` to combine `bibentry` objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use `bibentry` to directly create a multiple
The `print` method for `bibentry` objects provides a choice between seven different styles: plain text (style "text"), BibTeX ("Bibtex"), a mixture of plain text and BibTeX as traditionally used for citations ("citation"), HTML ("html"), LaTeX ("latex"), R code ("R"), and a simple copy of the `textVersion` elements (style "textVersion"). The "text", "html" and "latex" styles make use of the `.bibstyle` argument using the `bibstyle` function. In addition, one can use the `macros` argument to provide additional (otherwise unknown, presumably LaTeX-style) Rd macros, either by giving the path to a file with Rd macros to be loaded via `loadRdMacros`, or an object with macros already loaded.

When printing `bibentry` objects in citation style, a header/footer for each item can be displayed as well as a mheader/mfooter for the whole vector of references.

The `print` method is based on a `format` method which provides the same styles, and for formatting as R code a choice between giving a character vector with one `bibentry()` call for each bibentry (as commonly used in ‘CITATION’ files), or a character string with one collapsed call, obtained by combining the individual calls with `c()` if there is more than one bibentry. This can be controlled by setting the option `collapse` to `FALSE` (default) or `TRUE`, respectively. (Printing in R style always collapses to a single call.) Further, for the "citation" style, `format()`'s optional argument `citation.bibtex.max` (with default `getOption("citation.bibtex.max")` which defaults to 1) determines for up to how many citation bibentries text style is shown together with bibtex, automatically.

It is possible to subscript `bibentry` objects by their keys (which are used for character subscripts if the names are `NULL`).

There is also a `toBibtex` method for direct conversion to BibTeX.

**Value**

`bibentry` produces an object of class "bibentry".

**Entry Types**

`bibentry` creates "bibentry" objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

- **Article**: An article from a journal or magazine.
- **Book**: A book with an explicit publisher.
- **InBook**: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.
- **InCollection**: A part of a book having its own title.
- **InProceedings**: An article in a conference proceedings.
- **Manual**: Technical documentation like a software manual.
- **MastersThesis**: A Master’s thesis.
- **Misc**: Use this type when nothing else fits.
- **PhdThesis**: A PhD thesis.
- **Proceedings**: The proceedings of a conference.
- **TechReport**: A report published by a school or other institution, usually numbered within a series.
- **Unpublished**: A document having an author and title, but not formally published.
Entry Fields

The argument of bibentry can be any number of BibTeX fields, including:

- **address**: The address of the publisher or other type of institution.
- **author**: The name(s) of the author(s), either as a `person` object, or as a character string which, as `person` correctly coerces to such.
- **booktitle**: Title of a book, part of which is being cited.
- **chapter**: A chapter (or section or whatever) number.
- **editor**: Name(s) of editor(s), same format as author.
- **institution**: The publishing institution of a technical report.
- **journal**: A journal name.
- **note**: Any additional information that can help the reader. The first word should be capitalized.
- **number**: The number of a journal, magazine, technical report, or of a work in a series.
- **pages**: One or more page numbers or range of numbers.
- **publisher**: The publisher’s name.
- **school**: The name of the school where a thesis was written.
- **series**: The name of a series or set of books.
- **title**: The work’s title.
- **url**: A URL for the reference. (If the URL is an expanded DOI, we recommend to use the ‘doi’ field with the unexpanded DOI instead.)
- **volume**: The volume of a journal or multi-volume book.
- **year**: The year of publication.

## Format in R style

## One bibentry() call for each bibentry:
writeLines(paste(format(bref, "R"), collapse = "\n\n"))

## One collapsed call:
writeLines(format(bref, "R", collapse = TRUE))
**browseEnv**

**Description**

The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

**Usage**

```r
browseEnv(envir = .GlobalEnv, pattern,
excludepatt = "last\.\warning",
html = .Platform$GUI != "AQUA",
expanded = TRUE, properties = NULL,
main = NULL, debugMe = FALSE)
```

**Arguments**

- `envir` an environment the objects of which are to be browsed.
- `pattern` a regular expression for object subselection is passed to the internal `ls()` call.
- `excludepatt` a regular expression for dropping objects with matching names.
- `html` is used to display the workspace on a HTML page in your favorite browser. The default except when running from R.app on macOS.
- `expanded` whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if html is set to FALSE.
- `properties` a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used.
- `main` a title string to be used in the browser; when NULL (as per default) a title is constructed.
- `debugMe` logical switch; if true, some diagnostic output is produced.

**Details**

Very experimental code: displays a static HTML page on all platforms except R.app on macOS.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the tkWidget package (from https://www.bioconductor.org).

**See Also**

- `str`, `ls`.

**Examples**

```r
if(interactive()) {
    ## create some interesting objects :
    ofa <- ordered(4:1)
    ex1 <- expression(1+ 0:9)
    ex3 <- expression(u, v, 1+ 0:9)
    example(factor, echo = FALSE)
    example(table, echo = FALSE)
    example(ftable, echo = FALSE)
    example(lm, echo = FALSE, ask = FALSE)
    example(str, echo = FALSE)
```
## and browse them:
browseEnv()

## a (simple) function's environment:
afl2 <- approxfun(1:2, 1:2, method = "const")
browseEnv(envir = environment(afl2))

---

**browseURL**

Load URL into an HTML Browser

### Description

Load a given URL into an HTML browser.

### Usage

```r
browseURL(url, browser = getOption("browser"),
          encodeIfNeeded = FALSE)
```

### Arguments

- `url`: a non-empty character string giving the URL to be loaded. Some platforms also accept file paths.
- `browser`: a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser. Under Windows `NULL` is also allowed (and is the default), and implies that the file association mechanism will be used.
- `encodeIfNeeded`: Should the URL be encoded by `URLEncode` before passing to the browser? This is not needed (and might be harmful) if the `browser` program/function itself does encoding, and can be harmful for `file://` URLs on some systems and for `http://` URLs passed to some CGI applications. Fortunately, most URLs do not need encoding.

### Details

The default browser is set by option "browser", in turn set by the environment variable `R_BROWSER` which is by default set in file `R_HOME/etc/renviron` to a choice made manually or automatically when R was configured. (See `Startup` for where to override that default value.) To suppress showing URLs altogether, use the value "false".

On many platforms it is best to set option "browser" to a generic program/script and let that invoke the user's choice of browser. For example, on macOS use `open` and on many other Unix-alikes use `xdg-open`.

If browser supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the "-remote openURL(...)" interface (which includes Mozilla and Opera), Galeon, KDE konqueror (`via kfmclient`) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser
is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "-remote" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if DISPLAY points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller’s responsibility to encode url if necessary (see URLencode).

To suppress showing URLs altogether, set browser = "false".

The behaviour for arguments url which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

**URL schemes**

Which URL schemes are accepted is platform-specific: expect ‘http://’, ‘https://’ and ‘ftp://’ to work, but ‘mailto:’ may or may not (and if it does may not use the user’s preferred email client).

For the ‘file://’ scheme the format accepted (if any) can depend on both browser and OS.

**Examples**

```r
## Not run: ## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")
browseURL("https://www.r-project.org")

## End(Not run)
```

---

**browseVignettes**  
*List Vignettes in an HTML Browser*

**Description**

List available vignettes in an HTML browser with links to PDF, LaTeX/noweb source, and (tangled) R code (if available).

**Usage**

```r
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)
```

**Arguments**

- `package` a character vector with the names of packages to search through, or NULL in which "all" packages (as defined by argument all) are searched.
- `lib.loc` a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
- `all` logical; if TRUE search all available packages in the library trees specified by `lib.loc`, and if FALSE, search only attached packages.
- `x` Object of class `browseVignettes`.
- `...` Further arguments, ignored by the `print` method.
Function `browseVignettes` returns an object of the same class; the print method displays it as an HTML page in a browser (using `browseURL`).

### See Also

`browseURL`, `vignette` 

### Examples

```r
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
```

### Description

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of `R` are included automatically.

### Usage

```r
bug.report(subject = "", address, 
    file = "R.bug.report", package = NULL, lib.loc = NULL, 
    ...) 
```

### Arguments

- **subject** Subject of the email.
- **address** Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).
- **file** filename to use (if needed) for setting up the email.
- **package** Optional character vector naming a single package which is the subject of the bug report.
- **lib.loc** A character vector describing the location of `R` library trees in which to search for the package, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.
- **...** additional named arguments such as `method` and `ccaddress` to pass to `create.post`. 

Details

If package is NULL or a base package, this opens the R bugs tracker at https://bugs.r-project.org/.

If package is specified, it is assumed that the bug report is about that package, and parts of its ‘DESCRIPTION’ file are added to the standard information. If the package has a non-empty BugReports field in the ‘DESCRIPTION’ file specifying the URL of a webpage, that URL will be opened using browseURL, otherwise an email directed to the package maintainer will be generated using create.post. If there is any other form of BugReports field or a Contact field, this is examined as it may provide a preferred email address.

Value

Nothing useful.

When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list r-devel@r-project.org is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type version in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.
For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a method that had a bug causing R’s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function `bug.report()`. For reports on R this will open the Web page at [https://bugs.r-project.org/](https://bugs.r-project.org/): for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on contributed packages should not be sent to the R bug tracker: rather make use of the package argument.

**Author(s)**

This help page is adapted from the Emacs manual and the R FAQ

`help.request` which you possibly should try before `bug.report`.

`create.post`, which handles emailing reports.

The R FAQ, also `sessionInfo()` from which you may add to the bug report.

---

**capture.output**

*Send Output to a Character String or File*

**Description**

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to `sink` in the same way that `with` is related to `attach`.

**Usage**

```r
capture.output(..., file = NULL, append = FALSE,
             type = c("output", "message"), split = FALSE)
```
### changedFiles

**Detect which Files Have Changed**

**Description**

`fileSnapshot` takes a snapshot of a selection of files, recording summary information about each. `changedFiles` compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

### Arguments

...  
Expressions to be evaluated.

**file**
A file name or a connection, or NULL to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit.

**append**
logical. If file a file name or unopened connection, append or overwrite?

**type**, **split**
are passed to `sink()`, see there.

### Details

An attempt is made to write output as far as possible to file if there is an error in evaluating the expressions, but for file = NULL all output will be lost.

Messages sent to `stderr()` (including those from `message`, `warning` and `stop`) are captured by type = "message". Note that this can be "unsafe" and should only be used with care.

### Value

A character string (if file = NULL), or invisible NULL.

### See Also

`sink`, `textConnection`

### Examples

```r
require(stats)
glmout <- capture.output(summary(glm(case ~ spontaneous+induced,  
data = infert, family = binomial())))
glmout[1:5]
capture.output(1+1, 2+2)
capture.output({1+1; 2+2})
```

```r
## Not run: ## on Unix-alike with a2ps available
op <- options(useFancyQuotes=FALSE)
pdf <- pipe("a2ps -o - | ps2pdf - tempout.pdf", "w")
capture.output(example(glm), file = pdf)
close(pdf); options(op) ; system("evince tempout.pdf &")
## End(Not run)
```
Usage

fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL,
    md5sum = FALSE, digest = NULL, full.names = length(path) > 1,
    ...)  

changedFiles(before, after, path = before$path, timestamp = before$timestamp,
    check.file.info = c("size", "isdir", "mode", "mtime"),
    md5sum = before$md5sum, digest = before$digest,
    full.names = before$full.names, ...)  

## S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)  

## S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)  

Arguments

path character vector; the path(s) to record.
file.info logical; whether to record file.info values for each file.
timestamp character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.
md5sum logical; whether MD5 summaries of each file should be taken as part of the snapshot.
digest a function or NULL; a function with header function(filename) which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.
full.names logical; whether full names (as in list.files) should be recorded. Must be TRUE if length(path) > 1.
... additional parameters to pass to list.files to control the set of files in the snapshots.
before, after objects produced by fileSnapshot; two snapshots to compare. If after is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in before as defaults.
check.file.info character string or NULL; which columns from file.info should be compared.
x character vector; which columns from file.info should be compared.
verbose logical; whether to list all data when printing.

Details

The fileSnapshot function uses list.files to obtain a list of files, and depending on the file.info, md5sum, and digest arguments, records information about each file.

The changedFiles function compares two snapshots.

If the timestamp argument to fileSnapshot is length 1, a file with that name is created. If it is length 1 in changedFiles, the file_test function is used to compare the age of all files common to both before and after to it. This test may be unreliable: it compares the current modification time of the after files to the timestamp; that may not be the same as the modification time when the
after snapshot was taken. It may also give incorrect results if the clock on the file system holding
the timestamp differs from the one holding the snapshot files.

If the check.file.info argument contains a non-empty character vector, the indicated columns
from the result of a call to file.info will be compared.

If md5sum is TRUE, fileSnapshot will call the tools::md5sum function to record the 32 byte MD5
checksum for each file, and changedFiles will compare the values. The digest argument allows
users to provide their own digest function.

Value

fileSnapshot returns an object of class "fileSnapshot". This is a list containing the fields

info a data frame whose rownames are the filenames, and whose columns contain the
requested snapshot data
path the normalized path from the call
timestamp, file.info, md5sum, digest, full.names a record of the other arguments from the call
args other arguments passed via ... to list.files.

changedFiles produces an object of class "changedFiles". This is a list containing

added, deleted, changed, unchanged character vectors of filenames from the before and after snapshots, with obvious
meanings
changes a logical matrix with a row for each common file, and a column for each com-
parison test. TRUE indicates a change in that test.

print methods are defined for each of these types. The print method for "fileSnapshot" objects
displays the arguments used to produce them, while the one for "changedFiles" displays the
added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing
all of the TRUE values.

Author(s)

Duncan Murdoch, using suggestions from Karl Millar and others.

file.info, file_test, md5sum.

Examples

# Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
chooseBioCmirror

Description

Interact with the user to choose a Bioconductor mirror.

Usage

chooseBioCmirror(graphics =getOption("menu.graphics"), ind = NULL,
local.only = FALSE)

Arguments

- **graphics**: Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package tcltk and an X server are available. Otherwise use a text menu.
- **ind**: Optional numeric value giving which entry to select.
- **local.only**: Logical, try to get most recent list from the Bioconductor master or use file on local disk only.

Details

This sets the option "BioC_mirror": it is used before a call to setRepositories. The out-of-the-box default for that option is NULL, which currently corresponds to the mirror https://bioconductor.org.

The ‘Bioconductor (World-wide)’ ‘mirror’ is a network of mirrors providing reliable world-wide access; other mirrors may provide faster access on a geographically local scale.

ind chooses a row in ‘R_HOME/doc/BioC_mirrors.csv’, by number.

Value

None: this function is invoked for its side effect of updating options("BioC_mirror").

See Also

setRepositories, chooseCRANmirror.
chooseCRANmirror

- **Select a CRAN Mirror**

**Description**

Interact with the user to choose a CRAN mirror.

**Usage**

```r
chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL, local.only = FALSE)

getCRANmirrors(all = FALSE, local.only = FALSE)
```

**Arguments**

- **graphics** Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package `tcltk` and an X server are available. Otherwise use a text menu.
- **ind** Optional numeric value giving which entry to select.
- **all** Logical, get all known mirrors or only the ones flagged as OK.
- **local.only** Logical, try to get most recent list from the CRAN master or use file on local disk only.

**Details**

A list of mirrors is stored in file `R_HOME/doc/CRAN_mirrors.csv`, but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function is called by a Windows GUI menu item and by `contrib.url` if it finds the initial dummy value of `options("repos")`.

HTTPS mirrors with mirroring over `ssh` will be offered in preference to other mirrors (which are listed in a sub-menu).

`ind` chooses a row in the list of current mirrors, by number. It is best used with `local.only = TRUE` and row numbers in `R_HOME/doc/CRAN_mirrors.csv`.

**Value**

None for `chooseCRANmirror()`, this function is invoked for its side effect of updating `options("repos")`.

`getCRANmirrors()` returns a data frame with mirror information.

**See Also**

`setRepositories`, `chooseBioCmirror`, `contrib.url`. 
The **R** core development team and the very active community of package authors have invested a lot of time and effort in creating **R** as it is today. Please give credit where credit is due and cite **R** and **R** packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base **R** system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package (using `readCitationFile` with `meta = packageDescription(package, lib.loc)` or auto-generates citation information from the ‘DESCRIPTION’ file.

In **R** >= 2.14.0, one can use a ‘Authors@R’ field in ‘DESCRIPTION’ to provide (**R** code giving) a **person** object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If only one reference is given, the print method for the object returned by `citation()` shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function `toBibtex()` (see the examples below).

The ‘CITATION’ file of an **R** package should be placed in the ‘inst’ subdirectory of the package source. The file is an **R** source file and may contain arbitrary **R** commands including conditionals.
and computations. Function `readCitationFile()` is used by `citation()` to extract the information in 'CITATION' files. The file is `source()`ed by the R parser in a temporary environment and all resulting bibliographic objects (specifically, of class "bibentry") are collected.

Traditionally, the 'CITATION' file contained zero or more calls to `citHeader`, then one or more calls to `citEntry`, and finally zero or more calls to `citFooter`, where in fact `citHeader` and `citFooter` are simply wrappers to `paste`, with their ... argument passed on to `paste` as is. The "bibentry" class makes for improved representation and manipulation of bibliographic information (in fact, the old mechanism is implemented using the new one), and one can write 'CITATION' files using the unified `bibentry` interface.

One can include an auto-generated package citation in the 'CITATION' file via `citation(auto = meta)`. `readCitationFile` makes use of the Encoding element (if any) of `meta` to determine the encoding of the file.

**Value**

An object of class "citation", inheriting from class "bibentry"; see there, notably for the `print` and `format` methods.

**See Also**

`bibentry`

**Examples**

```r
## the basic R reference
citation()

## references for a package -- might not have these installed
if(nchar(system.file(package = "lattice"))) citation("lattice")
if(nchar(system.file(package = "foreign"))) citation("foreign")

## extract the bibtex entry from the return value
x <- citation()
toBibtex(x)

## A citation with more than one bibentry:
cm <- tryCatch(citation("mgcv"),
   error = function(e) {
     warning("Recommended package 'mgcv' is not installed properly")
     stop(e$message) })
cm # short entries (2-3 lines each)
print(cm, bibtex = TRUE) # each showing its bibtex code
```

---

**cite**

*Cite a Bibliography Entry*
Description

Cite a bibentry object in text. The cite() function uses the cite() function from the default bibstyle if present, or citeNatbib() if not. citeNatbib() uses a style similar to that used by the LaTeX package natbib.

Usage

cite(keys, bib, ...)  
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,  
mode = c("authoryear", "numbers", "super"),  
abbreviate = TRUE, longnamesfirst = TRUE,  
bibpunct = c("(" , ")", ";", "a", ",", ","), previous)

Arguments

keys A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.
bib A "bibentry" object containing the list of documents in which to find the keys.
... Additional arguments to pass to the cite() function for the default style.
textual Produce a "textual" style of citation, i.e. what \citet would produce in LaTeX.
before Optional text to display before the citation.
after Optional text to display after the citation.
mode The "mode" of citation.
abbreviate Whether to abbreviate long author lists.
longnamesfirst If abbreviate == TRUE, whether to leave the first citation long.
bibpunct A vector of punctuation to use in the citation, as used in natbib. See the Details section.
previous A list of keys that have been previously cited, to be used when abbreviate == TRUE and longnamesfirst == TRUE

Details

Argument names are chosen based on the documentation for the LaTeX natbib package. See that documentation for the interpretation of the bibpunct entries.

The entries in bibpunct are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the "mode": "n" for numbers, "s" for superscripts, anything else for author-year.
5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if mode is specified, it overrides the mode specification in bibpunct[4]. Partial matching is used for mode.

The defaults for citeNatbib have been chosen to match the JSS style, and by default these are used in cite. See bibstyle for how to set a different default style.
A single element character string is returned, containing the citation.

Duncan Murdoch

Examples

```r
## R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2013,
  url = "https://www.R-project.org/",
  key = "R"
)

## References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = c(
      person("Angelo", "Canty", role = "aut",
        comment = "S original"),
      person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
        comment = "R port, author of parallel support",
        email = "ripley@stats.ox.ac.uk"),
    ),
    year = "2012",
    note = "R package version 1.3-4",

    key = "boot-package"
  ),
  bibentry(
    bibtype = "Book",
    title = "Bootstrap Methods and Their Applications",
    author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]")",
    year = "1997",
    publisher = "Cambridge University Press",
    address = "Cambridge",
    isbn = "0-521-57391-2",
    url = "http://statwww.epfl.ch/davison/BMA/",
    key = "boot-book"
  )
)

## Combine and cite
refs <- c(rref, bref)
cite("R, boot-package", refs)
```

## Cite numerically
citEntry <- tools::getBibstyle()
tools::bibstyle("JSSnumbered", .init = TRUE,
  fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
  cite = function(key, bib, ...) citeMatbib(key, bib, mode = "numbers",
    bibpunct = c("[", ",", ";", "n", ",", ","), ...)
  )

cite("R, boot-package", refs, textual = TRUE)

## restore the old style
tools::bibstyle(savestyle, .default = TRUE)

---

citEntry

Bibliography Entries (Older Interface)

Description

Functionality for specifying bibliographic information in enhanced BibTeX style.

Usage

citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)
citFooter(...)

Arguments

entry a character string with a BibTeX entry type. See section Entry Types in bibentry for details.
textVersion a character string with a text representation of the reference.
header a character string with optional header text.
footer a character string with optional footer text.
... for citEntry, arguments of the form tag=value giving the fields of the entry, with tag and value the name and value of the field, respectively. See section Entry Fields in bibentry for details. For citHeader and citFooter, character strings.

Value

citEntry produces an object of class "bibentry".

See Also
citation for more information about citing R and R packages and 'CITATION' files; bibentry for the newer functionality for representing and manipulating bibliographic information.
close.socket  

Close a Socket

Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

Usage

close.socket(socket, ...)

Arguments

socket  a socket object
...  further arguments passed to or from other methods.

Value

logical indicating success or failure

Author(s)

Thomas Lumley

See Also

make.socket, read.socket

Compiling in support for sockets was optional prior to R 3.3.0: see capabilities("sockets") to see if it is available.

combn  

Generate All Combinations of n Elements, Taken m at a Time

Description

Generate all combinations of the elements of x taken m at a time. If x is a positive integer, returns all combinations of the elements of seq(x) taken m at a time. If argument FUN is not NULL, applies a function given by the argument to each point. If simplify is FALSE, returns a list; otherwise returns an array, typically a matrix. ... are passed unchanged to the FUN function, if specified.

Usage

combn(x, m, FUN = NULL, simplify = TRUE, ...)
Arguments

- **x**: vector source for combinations, or integer `n` for `x <- seq_len(n)`.
- **m**: number of elements to choose.
- **FUN**: function to be applied to each combination; default `NULL` means the identity, i.e., to return the combination (vector of length `m`).
- **simplify**: logical indicating if the result should be simplified to an array (typically a matrix); if FALSE, the function returns a list. Note that when `simplify = TRUE` as by default, the dimension of the result is simply determined from `FUN(1st combination)` (for efficiency reasons). This will badly fail if `FUN(u)` is not of constant length.
- ... optionally, further arguments to `FUN`.

Details

Factors `x` are accepted.

Value

A **list** or **array**, see the `simplify` argument above. In the latter case, the identity `dim(combn(n, m)) == c(m, choose(n, m))` holds.

Author(s)

Scott Chasalow wrote the original in 1994 for S. R package **combinat** and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of `simplify = TRUE`, e.g., for `combn(5, 5)`.

References

See Also

**choose** for fast computation of the number of combinations. **expand.grid** for creating a data frame from all combinations of factors or vectors.

Examples

```r
combn(letters[1:4], 2)
(m <- combn(10, 5, min))  # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m),
          c(2, 3, round(choose(15, 6))) == dim(mm))
```

```r
## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)
```

```r
## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
#table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))
```

```r
## Assuring the identity
```
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(nn <- combn(n, m)),
    dim(nn) == c(m, choose(n, m)))

---

**compareVersion**

*Compare Two Package Version Numbers*

**Description**

Compare two package version numbers to see which is later.

**Usage**

```r
compareVersion(a, b)
```

**Arguments**

- `a`, `b` Character strings representing package version numbers.

**Details**

R package version numbers are of the form `x.y-z` for integers `x`, `y` and `z`, with components after `x` optionally missing (in which case the version number is older than those with the components present).

**Value**

0 if the numbers are equal, -1 if b is later and 1 if a is later (analogous to the C function `strcmp`).

**See Also**

`package_version`, `library`, `packageStatus`.

**Examples**

```r
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0","7.1-12")
```

---

**COMPILE**

*Compile Files for Use with R*

**Description**

Compile given source files so that they can subsequently be collected into a shared object using `R CMD SHLIB` or an executable program using `R CMD LINK`.

**Usage**

```r
R CMD COMPILE [options] srcfiles
```
Arguments

srcfiles A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions `.c', `.cc' (or `.cpp'), `.m', `.mm' (or `.M'), `.F' and `.f90' or `.f95', respectively.

options A list of compile-relevant settings, or for obtaining information about usage and version of the utility.

Details

R CMD SHLIB can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to R CMD SHLIB is more reliable.

Ratfor is not supported. If you have Ratfor source code, you need to convert it to FORTRAN. (On some Solaris systems mixing Ratfor and FORTRAN code will work.)

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on macOS.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `.o' file is present.

Note

Some binary distributions of R have COMPILE in a separate bundle, e.g. an R-devel RPM. This is not available on Windows.

See Also

LINK, SHLIB, dyn.load; the section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).

contrib.url

Find Appropriate Paths in CRAN-like Repositories

description

contrib.url adds the appropriate type-specific path within a repository to each URL in repos.

Usage

contrib.url(repo, type = getOption("pkgType"))

Arguments

repos character vector, the base URL(s) of the repositories to use.

type character string, indicating which type of packages: see install.packages.
count.fields

Description

count.fields counts the number of fields, as separated by sep, in each of the lines of file read.

Usage

count.fields(file, sep = "", quote = "\"", skip = 0,
               blank.lines.skip = TRUE, comment.char = "#")

Arguments

file   a character string naming an ASCII data file, or a connection, which will be opened if necessary, and if so closed at the end of the function call.
sep    the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.
quote  the set of quoting characters
skip   the number of lines of the data file to skip before beginning to read data.
blank.lines.skip   logical: if TRUE blank lines in the input are ignored.
comment.char   character: a character vector of length one containing a single character or an empty string.

Details

This used to be used by read.table and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see scan.

Consistent with scan, count.fields allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.
create.post

Ancillary Function for Preparing Emails and Postings

Description
An ancillary function used by bug.report and help.request to prepare emails for submission to package maintainers or to R mailing lists.

Usage
create.post(instructions = character(), description = "post",
subject = "",
method = getOption("mailer"),
address = "the relevant mailing list",
ccaddress = getOption("ccaddress", ""),
filename = "R.post", info = character())

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instructions</td>
<td>Character vector of instructions to put at the top of the template email.</td>
</tr>
<tr>
<td>description</td>
<td>Character string: a description to be incorporated into messages.</td>
</tr>
<tr>
<td>subject</td>
<td>Subject of the email. Optional except for the &quot;mailx&quot; method.</td>
</tr>
<tr>
<td>method</td>
<td>Submission method, one of &quot;none&quot;, &quot;mailto&quot;, &quot;gnudoit&quot;, &quot;ess&quot; or (Unix only) &quot;mailx&quot;. See ‘Details’.</td>
</tr>
<tr>
<td>address</td>
<td>Recipient’s email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).</td>
</tr>
<tr>
<td>ccaddress</td>
<td>Optional email address for copies with the &quot;mailx&quot; and &quot;mailto&quot; methods. Use ccaddress = &quot;&quot; for no copy.</td>
</tr>
<tr>
<td>filename</td>
<td>Filename to use for setting up the email (or storing it when method is &quot;none&quot; or sending mail fails).</td>
</tr>
<tr>
<td>info</td>
<td>character vector of information to include in the template email below the ‘please do not edit the information below’ line.</td>
</tr>
</tbody>
</table>

Value
A vector with the numbers of fields found.

See Also
read.table

Examples

cat("NAME", "1:John", "2:Paul", file = "foo", sep = "\n")
count.fields("foo", sep = ":")
unlink("foo")

create.post
Details

What this does depends on the method. The function first creates a template email body.

none A file editor (see file.edit) is opened with instructions and the template email. When this returns, the completed email is in file ready to be read/pasted into an email program.

mailto This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on macOS and Windows, and where xdg-open is available and configured on other Unix-alikes: if that fails it tries the browser set by R_BROWSER).

This is the ‘factory-fresh’ default method.

mailx (Unix-alikes only.) A file editor (see file.edit) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as mailx, to the address (and optionally, the Cc: address) given.

gnudoit An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the gnudoit program to be available. Currently subject is ignored.

ess The body of the template email is sent to stdout.

Value

Invisible NULL.

See Also

bug.report, help.request.

data

Data Sets

Description

Loads specified data sets, or list the available data sets.

Usage

data(..., list = character(), package = NULL, lib.loc = NULL, verbose = getOption("verbose"), envir = .GlobalEnv)

Arguments

... literal character strings or names.
list a character vector.
package a character vector giving the package(s) to look in for data sets, or NULL.
By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory.
lib.loc a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
verbose a logical. If TRUE, additional diagnostics are printed.
envir the environment where the data should be loaded.
Currently, four formats of data files are supported:

1. files ending `.R` or `.r` are `source()`d in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the `utils` package is attached, in case it had been run via `utils::data`.)
2. files ending `.RData` or `.rda` are loaded.
3. files ending `.tab`, `.txt` or `.TXT` are read using `read.table(..., header = TRUE, as.is=FALSE)`, and hence result in a data frame.
4. files ending `.csv` or `.CSV` are read using `read.table(..., header = TRUE, sep = "","", as.is=FALSE)`, and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `.txt`, `.tab` or `.csv` can be compressed, with or without further extension `.gz`, `.bz2` or `.xz`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (`.R` or `.r`, and `.RData` or `.rda` files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, `data` lists the available data sets. It looks for a new-style data index in the `Meta` or, if this is not found, an old-style `.00Index` file in the `data` directory of each specified package, and uses these files to prepare a listing. If there is a `data` area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class "packageIQR". The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1 (beavers)` which tells us that dataset `beaver1` can be retrieved by the call `data(beaver1).

If `lib.loc` and package are both `NULL` (the default), the data sets are searched for in all the currently loaded packages then in the `data` directory (if any) of the current working directory.

If `lib.loc = NULL` but package is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see `.libPaths`).

If `lib.loc` is specified (and not `NULL`), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the `data` directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL`, the default).

Value
A character vector of all data sets specified, or information about all available data sets in an object of class "packageIQR" if none were specified.

Good practice
`data()` was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use. That need has been almost entirely superseded by lazy-loading of datasets.
The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of data within a function without an envir argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by data(..., envir = environment()). However, two alternatives are usually preferable, both described in the ‘Writing R Extensions’ manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file ‘R/sysdata.rda’ in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees mytable as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by ::, e.g., survival::survexp.us.

Note

One can take advantage of the search order and the fact that a ‘.R’ file will change directory. If raw data are stored in ‘mydata.txt’ then one can set up ‘mydata.R’ to read ‘mydata.txt’ and pre-process it, e.g., using transform. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the ‘.R’ file can effectively contain a metadata specification for the plaintext formats.

help for obtaining documentation on data sets, save for creating the second (‘.rda’) kind of data, typically the most efficient one.

The ‘Writing R Extensions’ for considerations in preparing the ‘data’ directory of a package.

Examples

```r
require(utils)
data()  # list all available data sets
try(data(package = "rpart") )  # list the data sets in the rpart package
data(USArrests, "VADeaths")  # load the data sets 'USArrests' and 'VADeaths'
## Not run:  ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests)  # give information on data set 'USArrests'
```

Description

A spreadsheet-like editor for entering or editing data.
Usage

data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)

Arguments

... A list of variables: currently these should be numeric or character vectors or list containing such vectors.
Modes The modes to be used for the variables.
Names The names to be used for the variables.
data A list of numeric and/or character vectors.
modes A list of length up to that of data giving the modes of (some of) the variables. list() is allowed.

Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

data.entry has side effects, any changes made in the spreadsheet are reflected in the variables. The functions de, de.ncols, de.setup and de.restore are designed to help achieve these side effects. If the user passes in a matrix, \( X \) say, then the matrix is broken into columns before dataentry is called. Then on return the columns are collected and glued back together and the result assigned to the variable \( X \). If you don’t want this behaviour use dataentry directly.

The primitive function is dataentry. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the dataentry window are returned as vectors in a list when the spreadsheet is closed.

de.ncols counts the number of columns which are supplied as arguments to data.entry. It attempts to count columns in lists, matrices and vectors. de.setup sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by de.restore.

Value

de and dataentry return the edited value of their arguments. data.entry invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user’s workspace.

Resources

The data entry window responds to X resources of class R_dataentry. Resources foreground, background and geometry are utilized.

Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.
There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left. PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including -.eE) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by > or <. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in var5 to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell and copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option de.cellwidth to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

*vi, edit*: edit uses dataentry to edit data frames.

### Examples

```r
# call data entry with variables x and y
## Not run: data.entry(x, y)
```

### Description

Set or unset debugging flags based on a call to a function. Takes into account S3/S4 method dispatch based on the classes of the arguments in the call.
Usage

debugcall(call, once = FALSE)
undebugcall(call)

Arguments

call  An R expression calling a function. The called function will be debugged. See Details.

once  logical; if TRUE, debugging only occurs once, as via debugonce. Defaults to FALSE

Details

debugcall debugs the non-generic function, S3 method or S4 method that would be called by evaluating call. Thus, the user does not need to specify the signature when debugging methods. Although the call is actually to the generic, it is the method that is debugged, not the generic, except for non-standard S3 generics (see isS3stdGeneric).

Value

debugcall invisibly returns the debugged call expression.

Note

Non-standard evaluation is used to retrieve the call (via substitute). For this reason, passing a variable containing a call expression, rather than the call expression itself, will not work.

See Also

dbug for the primary debugging interface

Examples

## Not run:
## Evaluate call after setting debugging
##
f <- factor(1:10)
res <- eval(debugcall(summary(f)))
## End(Not run)

debugger  

Description

Post-Mortem Debugging

Functions to dump the evaluation environments (frames) and to examine dumped frames.

Usage

dump.frames(dumpto = "last.dump", to.file = FALSE,
               include.GlobalEnv = FALSE)
debugger(dump = last.dump)
Arguments

dump.to  a character string. The name of the object or file to dump to.
to.file  logical. Should the dump be to an R object or to a file?
include.GlobalEnv  logical indicating if a copy of the .GlobalEnv environment should be included in addition to the sys.frames(). Will be particularly useful when used in a batch job.
dump  an R dump object created by dump.frames.

Details

To use post-mortem debugging, set the option error to be a call to dump.frames. By default this dumps to an R object last.dump in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to save). The dumped object contain the call stack, the active environments and the last error message as returned by geterrmessage.

When dumping to file, dump.to gives the name of the dumped object and the file name has ‘.rda’ appended.

A dump object of class "dump.frames" can be examined by calling debugger. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the browser called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any ... argument.

If dump.frames is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

Value

Invisible NULL.

Note

Functions such as sys.parent and environment applied to closures will not work correctly inside debugger.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

demo

### Demonstrations of R Functionality

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

#### Usage

demo(topic, package = NULL, lib.loc = NULL,
character.only = FALSE, verbose = getOption("verbose"),
echo = TRUE, ask = getOption("demo.ask"),
encoding = getOption("encoding"))

Arguments

- **topic**: the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.
- **package**: a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **character.only**: logical; if TRUE, use topic as character string.
- **verbose**: a logical. If TRUE, additional diagnostics are printed.
- **echo**: a logical. If TRUE, show the R input when sourcing.
- **ask**: a logical (or "default") indicating if `devAskNewPage(ask = TRUE)` should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to TRUE and the session is interactive, the user is asked to press RETURN to start.
- **encoding**: See `source`. If the package has a declared encoding, that takes preference.

Details

If no topics are given, `demo` lists the available demos. The corresponding information is returned in an object of class "packageIQR".

See Also

- `source` and `devAskNewPage` which are called by `demo`.

Examples

demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)
## End(Not run)

## Find the location of a demo

```r
system.file("demo", "lm.glm.R", package = "stats")
```

---

### Description

This function can be used to download a file from the Internet.

### Usage

```r
download.file(url, destfile, method, quiet = FALSE, mode = "w",
cacheOK = TRUE,
extra = getOption("download.file.extra"), ...)
```

### Arguments

- `url` A character string naming the URL of a resource to be downloaded.
- `destfile` A character string with the name where the downloaded file is saved. Tilde-expansion is performed.
- `method` Method to be used for downloading files. Current download methods are "internal", "wininet" (Windows only) "libcurl", "wget" and "curl", and there is a value "auto": see 'Details' and 'Note'. The method can also be set through the option "download.file.method": see `options()`.
- `quiet` If TRUE, suppress status messages (if any), and the progress bar.
- `mode` character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Not used for methods "wget" and "curl".
- `cacheOK` logical. Is a server-side cached value acceptable?
- `extra` character vector of additional command-line arguments for the "wget" and "curl" methods.
- `...` allow additional arguments to be passed, unused.

### Details

The function `download.file` can be used to download a single file as described by `url` from the Internet and store it in `destfile`. The `url` must start with a scheme such as `http://`, `https://`, `ftp://` or `file://`.

If `method = "auto"` is chosen (the default), on a Unix-alike method "libcurl" is used except "internal" for `file://` URLs.

Method "libcurl" uses the library of that name (http://curl.haxx.se/libcurl/). It provides (non-blocking) access to `https://` and (usually) `ftps://` URLs. There is support for simultaneous downloads, so `url` and `destfile` can be character vectors of the same length greater than one (but the method has to be specified explicitly and not via "auto"). For a single URL and quiet = FALSE a progress bar is shown in interactive use.
For methods "wget" and "curl" a system call is made to the tool given by method, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

cacheOK = FALSE is useful for 'http://' and 'https:// URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by available.packages.

The "libcurl" and "wget" methods follow 'http://' and 'https://' redirections to any scheme they support: the "internal" method follows 'http://' to 'http://' redirections only. (For method "curl" use argument extra = "-L". To disable redirection in wget, use extra = "--max-redirect=0".) The "wininet" method supports some redirections but not all. (For method "libcurl", messages will quote the endpoint of redirections.)

Note that 'https:// URLs are not supported by the "internal" method but are supported by the "libcurl" and the "wininet" method on Windows.

See url for how 'file:// URLs are interpreted, especially on Windows. The "internal" and "wininet" methods do not percent-decode 'file:// URLs, but the "libcurl" and "curl" methods do: method "wget" does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see URLencode), but it seems the "wininet" method does.

The remaining details apply to the "internal", "wininet" and "libcurl" methods only.

The timeout for many parts of the transfer can be set by the option timeout which defaults to 60 seconds.

The level of detail provided during transfer can be set by the quiet argument and the internet.info option: the details depend on the platform and scheme. For the "internal" method setting option internet.info to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

Code written to download binary files must use mode = "wb", but the problems incurred by a text transfer will only be seen on Windows.

Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

What happens to the destination file(s) in the case of error depends on the method and R version.

Currently the "internal", "wininet" and "libcurl" methods will remove the file if there the URL is unavailable except when mode specifies appending when the file should be unchanged.

Setting Proxies

The next two paragraphs apply to the internal code only.

Proxies can be specified via environment variables. Setting no_proxy to * stops any proxy being tried. Otherwise the setting of http_proxy or ftp_proxy (or failing that, the all uppercase version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by ftp_proxy_user and ftp_proxy_password.

The form of http_proxy should be http://proxy.dom.com/ or http://proxy.dom.com:8080/ where the port defaults to 80 and the trailing slash may be omitted. For ftp_proxy use the form
ftp://proxy.dom.com:3128/ where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling `Sys.setenv`. Usernames and passwords can be set for HTTP proxy transfers via environment variable `http_proxy_user` in the form `user:password`. Alternatively, `http_proxy` can be of the form `http://user:pass@proxy.dom.com:8080/` for compatibility with `wget`. Only the HTTP/1.0 basic authentication scheme is supported.

Much the same scheme is supported by `method = "libcurl"`, including `no_proxy`, `http_proxy` and `ftp_proxy`, and for the last two a contents of `[user:password@]machine[:port]` where the parts in brackets are optional. See `http://curl.haxx.se/libcurl/c/libcurl-tutorial.html` for details.

**Secure URLs**

Methods which access 'https://' and 'ftps://' URLs should try to verify the site certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see `http://curl.haxx.se/docs/sslcerts.html`.

This is an issue for `method = "libcurl"` on Windows, where the OS does not provide a suitable CA certificate bundle, so by default on Windows certificates are not verified. To turn verification on, set environment variable `CURL_CA_BUNDLE` to the path to a certificate bundle file, usually named 'ca-bundle.crt' or 'curl-ca-bundle.crt'. (This is normally done for a binary installation of R, which installs `R_HOME/etc/curl-ca-bundle.crt` and sets `CURL_CA_BUNDLE` to point to it if that environment variable is not already set.) For an updated certificate bundle, see `http://curl.haxx.se/docs/sslcerts.html`. Currently one can download a copy from `https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt` and set `CURL_CA_BUNDLE` to the full path to the downloaded file.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).

**FTP sites**

'ftp:' URLs are accessed using the FTP protocol which has a number of variants. One distinction is between 'active' and '(extended) passive' modes: which is used is chosen by the client. The "internal" and "libcurl" methods use passive mode, and that is almost universally used by browsers. Prior to R 3.2.3 the "wininet" method used active mode: nowadays it first tries passive and then active.

**Good practice**

Setting the method should be left to the end user. Neither of the `wget` nor `curl` commands is widely available: you can check if one is available via `Sys.which`, and should do so in a package or script. If you use `download.file` in a package or script, you must check the return value, since it is possible that the download will fail with a non-zero status but not an R error. (This was more likely prior to R 3.4.0.)

The supported methods do change: method `libcurl` was introduced in R 3.2.0 and is still optional on Windows – use `capabilities("libcurl")` in a program to see if it is available.

**Note**

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.
download.packages

Methods "wget" and "curl" are mainly for historical compatibility but provide may provide capabilities not supported by the "libcurl" or "wininet" methods.

Method "wget" can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for wget.

wget (http://www.gnu.org/software/wget/) is commonly installed on Unix-alikes (but not macOS). Windows binaries are available from Cygwin, gnuwin32 and elsewhere.

curl (http://curl.haxx.se/) is installed on macOS and commonly on Unix-alikes. Windows binaries are available at that URL.

See Also

options to set the HTTPUserAgent, timeout and internet.info options used by some of the methods.

url for a finer-grained way to read data from URLs.

url.show, available.packages, download.packages for applications.

Contributed package Rcurl provides more comprehensive facilities to download from URLs.

download.packages   Download Packages from CRAN-like Repositories

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

Usage

download.packages(pkgs, destdir, available = NULL, repos = getOption("repos"), contriburl = contrib.url(repos, type), method, type = getOption("pkgType"), ...)

Arguments

pkgs character vector of the names of packages whose latest available versions should be downloaded from the repositories.
destdir directory where downloaded packages are to be stored.
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages.
repos character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "https://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN".
contriburl URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD. Overrides argument repos.
method Download method, see download.file.
type character string, indicate which type of packages: see install.packages and 'Details'.
... additional arguments to be passed to download.file and available.packages.
Details
download.packages takes a list of package names and a destination directory, downloads the newest versions and saves them in destdir. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file:," then the packages are not downloaded but used directly. Both "file:" and "file:///" are allowed as prefixes to a file path. Use the latter only for URLs: see url for their interpretation. (Other forms of ‘file://’ URLs are not supported.)
For download.packages, type = "both" looks at source packages only.

Value
A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

See Also
available.packages, contrib.url.
The main use is by install.packages.
See download.file for how to handle proxies and other options to monitor file transfers.
The ‘R Installation and Administration’ manual for how to set up a repository.
**Details**

`edit` invokes the text editor specified by `editor` with the object `name` to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

`data.entry` can be used to edit data, and is used by `edit` to edit matrices and data frames on systems for which `data.entry` is available.

It is important to realize that `edit` does not change the object called `name`. Instead, a copy of `name` is made and it is that copy which is changed. Should you want the changes to apply to the object `name` you must assign the result of `edit` to `name`. (Try `fix` if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes file to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()`, with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given name in the window header.

**Note**

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

**See Also**

`edit.data.frame`, `data.entry`, `fix`.

**Examples**

```r
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```
## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
     edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)

Arguments

**name**
A data frame or (numeric, logical or character) matrix.

**factor.mode**
How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated.

**edit.row.names**
logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with NULL row names.

... further arguments passed to or from other methods.

Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to character unless numeric (in the sense of is.numeric), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor’s facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if edit.row.names = FALSE and the number of rows is unchanged, and from the edited output if edit.row.names = TRUE and there are no duplicates. (If the row.names column is incomplete, it is extended by entries like row223.) In all other cases the row names are replaced by seq(1:length = n rows).
For a matrix, colnames will be added (of the form col7) if needed. The rownames will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise NULL), and from the edited output if `edit.row.names = TRUE`. (If the row.names column is incomplete, it is extended by entries like row223.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

### Value

The edited data frame or matrix.

### Note

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

data.entry, edit

### Examples

```r
## Not run:
edit(InsectSprays)
edi t(InsectSprays, factor.mode = "numeric")
## End(Not run)
```

---

### Description

Run all the R code from the Examples part of R’s online help topic topic with possible exceptions `dontrun`, `dontshow`, and `donttest`, see ‘Details’ below.

### Usage

```r
e xample(topic, package = NULL, lib.loc = NULL, 
character.only = FALSE, give.lines = FALSE, local = FALSE, 
echo = TRUE, verbose = getOption("verbose"), 
setRNG = FALSE, ask = getOption("example.ask"), 
prompt.prefix = abbreviate(topic, 6), 
run.dontrun = FALSE, run.donttest = interactive())
```
Arguments

- **topic**: name or literal character string: the online help topic the examples of which should be run.
- **package**: a character vector giving the package names to look into for the topic, or NULL (the default), when all packages on the search path are used.
- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
- **character.only**: a logical indicating whether topic can be assumed to be a character string.
- **give.lines**: logical: if true, the lines of the example source code are returned as a character vector.
- **local**: logical: if TRUE evaluate locally, if FALSE evaluate in the workspace.
- **echo**: logical; if TRUE, show the R input when sourcing.
- **verbose**: logical; if TRUE, show even more when running example code.
- **setRNG**: logical or expression; if not FALSE, the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. setRNG = TRUE sets the same state as R CMD check does for running a package’s examples. This is currently equivalent to setRNG = (RNGkind("default", "default"); set.seed(1)).
- **ask**: logical (or "default") indicating if devAskNewPage(ask = TRUE) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if echo == TRUE and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.
- **prompt.prefix**: character; prefixes the prompt to be used if echo = TRUE.
- **run.dontrun**: logical indicating that \dontrun should be ignored.
- **run.donttest**: logical indicating that \donttest should be ignored.

Details

If lib.loc is not specified, the packages are searched for amongst those already loaded, then in the libraries given by .libPaths(). If lib.loc is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If local = TRUE objects are not created in the workspace and so not available for examination after example completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the manual *Writing R Extensions*, the author of the help page can markup parts of the examples for exception rules:

- **dontrun** encloses code that should not be run.
- **dontshow** encloses code that is invisible on help pages, but will be run both by the package checking tools, and the example() function. This was previously testonly, and that form is still accepted.
- **donttest** encloses code that typically should be run, but not during package checking. The default run.donttest = interactive() leads example() use in other help page examples to skip \donttest sections appropriately.
Value

The value of the last evaluated expression, unless give.lines is true, where a character vector is returned.

demo

Examples

```r
example(InsectSprays)
## force use of the standard package 'stats':
exa("smooth", package = "stats", lib.loc = .Library)

## set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2

## Exploring examples code:
## How large are the examples of "lm...()" functions?
lmex <- sapply(apropos("lm", mode = "function"),
                example, character.only = TRUE, give.lines = TRUE)
sapply(lmex, length)
```

Description

Edit one or more files in a text editor.

Usage

```r
file.edit(..., title = file, editor = getOption("editor"),
          fileEncoding = "")
```
Arguments

\begin{itemize}
\item \textbf{...} one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see \texttt{path.expand}.
\item \textbf{title} the title to use in the editor; defaults to the filename.
\item \textbf{editor} the text editor to be used. See ‘Details’.
\item \textbf{fileEncoding} the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for \texttt{file}.
\end{itemize}

Details

The behaviour of this function is very system dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The \texttt{title} argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for \texttt{editor} is system-dependent. On Windows it defaults to "internal", the script editor, and in the macOS GUI the document editor is used whatever the value of \texttt{editor}. On Unix the default is set from the environment variables \texttt{EDITOR} or \texttt{VISUAL} if either is set, otherwise \texttt{vi} is used.

## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")
## End(Not run)
\end{verbatim}

\texttt{file_test} \hspace{1cm} \textit{Shell-style Tests on Files}

Description

Utility for shell-style file tests.

Usage

\texttt{file_test(op, x, y)}

Arguments

\begin{itemize}
\item \textbf{op} a character string specifying the test to be performed. Unary tests (only \texttt{x} is used) are "-f" (existence and not being a directory), "-d" (existence and directory) and "-x" (executable as a file or searchable as a directory). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist.
\item \textbf{x, y} character vectors giving file paths.
\end{itemize}
Details

‘Existence’ here means being on the file system and accessible by the stat system call (or a 64-bit extension) — on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see file.access.

See Also

file.exists which only tests for existence (test -e on some systems) but not for not being a directory.

file.path, file.info

Examples

dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))

findLineNum

Find the Location of a Line of Source Code, or Set a Breakpoint There

Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with keep.source = TRUE.

Usage

findLineNum(srcfile, line, nameonly = TRUE, envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE, envir = parent.frame(), lastenv, verbose = TRUE, tracer, print = FALSE, clear = FALSE, ...)

Arguments

srcfile The name of the file containing the source code.
line The line number within the file. See Details for an alternate way to specify this.
nameonly If TRUE (the default), we require only a match to basename(srcfile), not to the full path.
envir Where do we start looking for function objects?
lastenv Where do we stop? See the Details.
verbose Should we print information on where breakpoints were set?
tracer An optional tracer function to pass to trace. By default, a call to browser is inserted.
print The print argument function to pass to trace.
clear If TRUE, call untrace rather than trace.
... Additional arguments to pass to trace.
Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grandparent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment `emptyenv()` if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for `trace` and `untrace`. It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "srcfile" object, or it may include a suffix like "filename.R#nn", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package namespace. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g., `envir = environment(foo)`), `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the `base` or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g., methods on primitive generics, are not yet supported.

Value

`findLineNum` returns a list of objects containing location information. A `print` method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

Duncan Murdoch

See Also

`trace`

Examples

```r
## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
```
fix

Description

fix invokes edit on x and then assigns the new (edited) version of x in the user’s workspace.

Usage

fix(x, ...)

Arguments

x

the name of an R object, as a name or a character string.

...

arguments to pass to editor: see edit.

Details

The name supplied as x need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under edit. See edit.data.frame for changes that can occur when editing a data frame or matrix.

See Also

edit, edit.data.frame

Examples

## Not run:
## Assume 'my.fun' is a user defined function :
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)
flush.console  

*Flush Output to a Console*

**Description**

This does nothing except on console-based versions of \( R \). On the macOS and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

**Usage**

`flush.console()`

---

format  

*Format Unordered and Ordered Lists*

**Description**

Format unordered (itemize) and ordered (enumerate) lists.

**Usage**

```r
formatUL(x, label = "*", offset = 0, 
       width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1, 
       width = 0.9 * getOption("width"))
```

**Arguments**

- **x**  
  a character vector of list items.

- **label**  
  a character string used for labelling the items.

- **offset**  
  a non-negative integer giving the offset (indentation) of the list.

- **width**  
  a positive integer giving the target column for wrapping lines in the output.

- **type**  
  a character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26. Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"I" (roman), respectively.

- **start**  
  a positive integer specifying the starting number of the first item in an ordered list.

**Value**

A character vector with the formatted entries.
### Description

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

### Usage

```r
getAnywhere(x)
argsAnywhere(x)
```

### Arguments

- `x`: a character string or name.

### Details

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.
**Value**

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

- **name**: the name searched for
- **objs**: a list of objects found
- **where**: a character vector explaining where the object(s) were found
- **visible**: logical: is the object visible
- **dups**: logical: is the object identical to one earlier in the list.

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by `args`.

**See Also**

- `getS3method` to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.
- `get`, `getFromNamespace`, `args`

**Examples**

```r
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

---

**getFromNamespace**  
*Utility Functions for Developing Namespaces*

**Description**

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the 'Note').

**Usage**

```r
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1, 
                  envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```
Arguments

- **x**: an object name (given as a character string).
- **value**: an R object.
- **ns**: a namespace, or character string giving the namespace.
- **pos**: where to look for the object: see `get`.
- **envir**: an alternative way to specify an environment to look in.
- **...**: arguments to pass to the editor: see `edit`.

Details

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for `get`: `ns` can also be the environment printed as `<namespace:foo>`.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes `edit` on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

Value

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the namespace.

Warning

`assignInNamespace` should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

Note

`assignInNamespace`, `assignInMyNamespace` and `fixInNamespace` change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used only for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

See Also

`get`, `fix`, `getS3method`
getParseData

Get Detailed Parse Information from Object

Description

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

Usage

getParseData(x, includeText = NA)
getParseText(parseData, id)

Arguments

x
an expression returned from parse, or a function or other object with source reference information

includeText
logical; whether to include the text of parsed items in the result

parseData
a data frame returned from getParseData

id
a vector of item identifiers whose text is to be retrieved

Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his parser package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the srcfile record associated with source references in the parsed code, and retrieved by the getParseData function.

Value

For getParseData:
If parse data is not present, NULL. Otherwise a data frame is returned, containing the following columns:

line1
integer. The line number where the item starts. This is the parsed line number called "parse" in getSrcLocation, which ignores #line directives.

col1
integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in getSrcLocation.

line2
integer. The line number where the item ends.
### getParseData

<table>
<thead>
<tr>
<th>col2</th>
<th>integer. The column number where the item ends.</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>integer. An identifier associated with this item.</td>
</tr>
<tr>
<td>parent</td>
<td>integer. The id of the parent of this item.</td>
</tr>
<tr>
<td>token</td>
<td>character string. The type of the token.</td>
</tr>
<tr>
<td>terminal</td>
<td>logical. Whether the token is “terminal”, i.e. a leaf in the parse tree.</td>
</tr>
<tr>
<td>text</td>
<td>character string. If includeText is TRUE, the text of all tokens; if it is NA (the default), the text of terminal tokens. If includeText == FALSE, this column is not included. Very long strings (with source of 1000 characters or more) will not be stored; a message giving their length and delimiter will be included instead.</td>
</tr>
</tbody>
</table>

The rownames of the data frame will be equal to the id values, and the data frame will have a "srcfile" attribute containing the srcfile record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For `getParseText`:
A character vector of the same length as id containing the associated text items. If they are not included in parseData, they will be retrieved from the original file.

**Note**

There are a number of differences in the results returned by `getParseData` relative to those in the original parser code:

- Fewer columns are kept.
- The internal token number is not returned.
- col1 starts counting at 1, not 0.
- The id values are not attached to the elements of the parse tree, they are only retained in the table returned by `getParseData`.
- #line directives are identified, but other comment markup (e.g., roxygen comments) are not.

**Author(s)**

Duncan Murdoch

**References**

**See Also**

parse, srcref

**Examples**

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
if (!is.null(d)) {
  plus <- which(d$token == "'+'")
  sum <- d$parent[plus]
```
getS3method

Get an S3 Method

Description

Get a method for an S3 generic, possibly from a namespace or the generic’s registry.

Usage

getS3method(f, class, optional = FALSE, envir = parent.frame())

Arguments

- `f` character: name of the generic.
- `class` character: name of the class.
- `optional` logical: should failure to find the generic or a method be allowed?
- `envir` the environment in which the method and its generic are searched first.

Details

S3 methods may be hidden in namespaces, and will not then be found by `get`: this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic \( f \) is called from: `getS3method` returns the method found if \( f \) were called from the same environment.

Value

The function found, or NULL if no function is found and optional = TRUE.

See Also

`methods`, `get`, `getAnywhere`

Examples

```r
require(stats)
exists("predict.ppr") # false
gets3method("predict", "ppr")
```
glob2rx

Change Wildcard or Globbing Pattern into Regular Expression

Description

Change wildcard aka globbing patterns into the corresponding regular expressions (regexp).

Usage

glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)

Arguments

- **pattern**: character vector
- **trim.head**: logical specifying if leading "^.*" should be trimmed from the result.
- **trim.tail**: logical specifying if trailing ".*$" should be trimmed from the result.

Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. ? is mapped to . (match a single character), * to .* (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even (, [ and { can be used in pattern, but glob2rx() may not work correctly with arbitrary characters in pattern.

Value

A character vector of the same length as the input pattern where each wildcard is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

regexp about regular expression, sub, etc about substitutions using regexps.

Examples

```r
stopifnot(glob2rx("abc.*") == "^abc\..",
glob2rx("a?b.*") == "^a.b\..",
glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\..*$",
glob2rx("*.doc") == "^.*\.doc$",
glob2rx("*.doc", trim.head = TRUE) == "\..doc$",
glob2rx("*.t\") == "^.*\..t",
glob2rx("*.t??") == "^.*\..t..$",
glob2rx("*[?]") == "^.*\[.."]
```
Description

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the `check` tool is applied to this package. The call to `globalVariables` will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to `codetools`. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressForeignCheck`, the names supplied are of variables used as NAME in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (.Call, .External, etc.) and argument counts will be checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

Usage

```r
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

Arguments

- `names`: The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.
- `package`: The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.
  
  When the call to `globalVariables` or `suppressForeignCheck` comes in the package’s source file, the argument is normally omitted, as in the example below.
- `add`: Should the contents of `names` be added to the current global variables or replace it?

Details

The lists of declared global variables and native symbol objects are stored in a metadata object in the package’s namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package’s source code.

The `check` command, as implemented in package `tools`, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.
Value

globalVariables returns the current list of declared global variables, possibly modified by this call.
suppressForeignCheck returns the current list of native symbol objects which are not to be checked.

Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in check and/or in codetools, so in this version the information is stored at the package level.

Author(s)

John Chambers and Duncan Murdoch

See Also
dontCheck.

Examples

### Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", "obj2"))

## To suppress messages about a run-time calculated native symbol,
## save it to a local variable.

## At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

## Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

## HOWEVER, it is much better practice to write code
## that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

## End(Not run)

|-- hasName
   |    | Check for Name

Description

hasName is a convenient way to test for one or more names in an R object.
Usage

```r
hasName(x, name)
```

Arguments

- `x`: Any object.
- `name`: One or more character values to look for.

Details

`hasName(x, name)` is defined to be equivalent to `name %in% names(x)`, though it will evaluate slightly more quickly. It is intended to replace the common idiom `!is.null(x$name)`. The latter can be unreliable due to partial name matching; see the example below.

Value

A logical vector of the same length as `name` containing `TRUE` if the corresponding entry is in `names(x)`.

See Also

- `%in%`
- `exists`

Examples

```r
x <- list(abc = 1, def = 2)
!is.null(x$abc) # correct
!is.null(x$a)   # this is the wrong test!
hasName(x, "abc")
hasName(x, "a")
```

Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since `head()` and `tail()` are generic functions, they may also have been extended to other classes.

Usage

```r
head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'data.frame'
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...)
## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'table'
head(x, n = 6L, ...)
```
## S3 method for class 'function'
head(x, n = 6L, ...)

tail(x, ...)

## Default S3 method:
tail(x, n = 6L, ...)

## S3 method for class 'data.frame'
tail(x, n = 6L, ...)

## S3 method for class 'matrix'
tail(x, n = 6L, addrownums = TRUE, ...)

## S3 method for class 'ftable'
tail(x, n = 6L, addrownums = FALSE, ...)

## S3 method for class 'table'
tail(x, n = 6L, addrownums = TRUE, ...)

## S3 method for class 'function'
tail(x, n = 6L, ...)

### Arguments

- **x**: an object
- **n**: a single integer. If positive or zero, size for the resulting object: number of elements for a vector (including lists), rows for a matrix or data frame or lines for a function. If negative, all but the \( n \) last/first number of elements of \( x \).
- **addrownums**: if there are no row names, create them from the row numbers.
- **...**: arguments to be passed to or from other methods.

### Details

For matrices, 2-dim tables and data frames, `head()` (tail()) returns the first (last) \( n \) rows when \( n \geq 0 \) or all but the last (first) \( n \) rows when \( n < 0 \). `head.matrix()` and `tail.matrix()` are exported. For functions, the lines of the deparsed function are returned as character strings.

If a matrix has no row names, then `tail()` will add row names of the form "[n,]" to the result, so that it looks similar to the last lines of \( x \) when printed. Setting `addrownums = FALSE` suppresses this behaviour.

### Value

An object (usually) like \( x \) but generally smaller. For ftable objects \( x \), a transformed `format(x)`.

### Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet.

### Examples

```r
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)

tail(letters)
tail(letters, n = -6L)
```
help is the primary interface to the help systems.

Arguments

- **topic**: usually, a name or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.

- **package**: a name or character vector giving the packages to look into for documentation, or NULL. By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. `(pkg_ref)` (see the examples).

- **lib.loc**: a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).

- **verbose**: logical; if TRUE, the file name is reported.

- **try.all.packages**: logical; see Note.

- **help_type**: character string: the type of help required. Possible values are "text", "html" and "pdf". Case is ignored, and partial matching is allowed.

Details

The following types of help are available:

- Plain text help
• HTML help pages with hyperlinks to other topics, shown in a browser by `browseURL`. (Where possible an existing browser window is re-used: the macOS GUI uses its own browser window.) If for some reason HTML help is unavailable (see `startDynamicHelp`), plain text help will be used instead.

• For help only, typeset as PDF – see the section on ‘Offline help’.

The ‘factory-fresh’ default is text help except from the macOS GUI, which uses HTML help displayed in its own browser window.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting `options(useFancyQuotes = FALSE)`.

topic is not optional: if it is omitted R will give

• If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.

• If `lib.loc` only is specified, a (text) list of available packages.

• Help on `help` itself if none of the first three arguments is specified.

Some topics need to be quoted (by backticks) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow reserved words (including if, else for, in, repeat, while, break and next). The other reserved words can be used as if they were names, for example TRUE, NA and Inf.

If multiple help files matching topic are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the loaded packages and then along `.libPaths()`.

**Offline help**

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file ‘Rhelp.cfg’ somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some environment variables are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration Manual’).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which is nowadays ignored). It accepts a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

**Note**

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are not searched.
If this search fails and argument try.all.packages is TRUE and neither packages nor lib.loc is specified, then all the packages in the known library trees are searched for help on topic and a list of (any) packages where help may be found is displayed (with hyperlinks for help_type = "html"). NB: searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

References

See Also

? for shortcuts to help topics.

help.search() or ?? for finding help pages on a vague topic; help.start() which opens the HTML version of the R help pages; library() for listing available packages and the help objects they contain; data() for listing available data sets; methods(). Use prompt() to get a prototype for writing help pages of your own package.

Examples

help()
help(help) # the same
help(lapply)
help("for") # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
  help(dgamma, help_type = "pdf")
  ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
  system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE) # reports can be found
    # in package 'splines'

## For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))
help.request

Description
Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

Usage
help.request(subject = "", address = "r-help@R-project.org", file = "R.help.request", ...)

Arguments
subject subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries.
address recipient’s email address.
file filename to use (if needed) for setting up the email.
... additional named arguments such as method and ccaddress to pass to create.post.

Details
This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see https://www.r-project.org/posting-guide.html).

The help.request function:

• asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response if given.
• checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
• asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to create.post.

Value
Nothing useful.

Author(s)
Heather Turner, based on the then current code and help page of bug.report().

See Also
The posting guide (https://www.r-project.org/posting-guide.html), also sessionInfo() from which you may add to the help request.
create.post.
help.search

Search the Help System

Description

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either fuzzy matching or regular expression matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

Usage

help.search(pattern, fields = c("alias", "concept", "title"),
apropos, keyword, whatis, ignore.case = TRUE,
package = NULL, lib.loc = NULL,
help.db = getOption("help.db"),
verbose = getOption("verbose"),
rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
types = getOption("help.search.types"))

Arguments

pattern

a character string to be matched in the specified fields. If this is given, the arguments apropos, keyword, and whatis are ignored.

fields

a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched.

apropos

a character string to be matched in the help page topics and title.

keyword

a character string to be matched in the help page 'keywords'. ‘Keywords’ are really categories: the standard categories are listed in file ‘R.home("doc")/KEYWORDS’ (see also the example) and some package writers have defined their own. If keyword is specified, agrep defaults to FALSE.

whatis

a character string to be matched in the help page topics.

ignore.case

a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.

package

a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by lib.loc are searched.

lib.loc

a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

help.db

a character string giving the file path to a previously built and saved help database, or NULL.
verbose logical; if TRUE, the search process is traced. Integer values are also accepted, with TRUE being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for verbose = 1 and a package-by-package list for verbose >= 2.

rebuild a logical indicating whether the help database should be rebuilt. This will be done automatically if lib.loc or the search path is changed, or if package is used and a value is not found.

agrep if NULL (the default unless keyword is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via agrep is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via grep. If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument max.distance in the documentation for agrep.

use_UTF8 logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in agrep to be Perl regexps.

types a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified.

field a single value of fields to search.

Details

Upon installation of a package, a pre-built help.search index is serialized as ‘hsearch.rds’ in the ‘Meta’ directory (provided the package has any help pages). Vignettes are also indexed in the ‘Meta/vignette.rds’ file. These files are used to create the help search database via hsearch_db.

The arguments apropos and whatis play a role similar to the Unix commands with the same names. Searching with agrep = FALSE will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session. Note that currently the aliases in the matching help files are not displayed.

As with ?, in ?? the pattern may be prefixed with a package name followed by :: or ::: to limit the search to that package.

For help files, ‘\keyword’ entries which are not among the standard keywords as listed in file ‘KEYWORDS’ in the R documentation directory are taken as concepts. For standard keyword entries different from ‘internal’, the corresponding descriptions from file ‘KEYWORDS’ are additionally taken as concepts. All ‘\concept’ entries used as concepts.

Vignettes are searched as follows. The "name" and "alias" are both the base of the vignette filename, and the "concept" entries are taken from the \VignetteKeyword entries. Vignettes are not classified using the help system "keyword" classifications. Demos are handled similarly to vignettes, without the "concept" search.

Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.
help.start

In R.app on macOS, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.
The internal format of the class is undocumented and subject to change.

See Also

hsearch.db for more information on the help search database employed, and for utilities to inspect available concepts and keywords.
help; help.start for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.
RSiteSearch to access an on-line search of R resources.
apropos uses regexps and has nice examples.

Examples

help.search("linear models") # In case you forgot how to fit linear models
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package

help.search("print") # All help pages with topics or title matching 'print'
help.search(apropos = "print") # The same
help.search(keyword = "hplot") # All help pages documenting high-level plots.
file.show(file.path(R.home("doc"), "KEYWORDS")) # show all keywords

## Help pages with documented topics starting with 'try'.
help.search("\btry", fields = "alias")

help.start

Hypertext Documentation

Description

Start the hypertext (currently HTML) version of R's online documentation.

Usage

help.start(update = FALSE, gui = "irrelevant",
    browser = getOption("browser"), remote = NULL)

Arguments

update logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if remote is non-NULL.)

gui just for compatibility with S-PLUS.
browser

the name of the program to be used as a hypertext browser. It should be in the
PATH, or a full path specified. Alternatively, it can be an R function which
will be called with a URL as its only argument. This option is normally unset on
Windows, when the file-association mechanism will be used.

remote

A character string giving a valid URL for the ‘R_HOME’ directory on a remote
location.

Details

Unless remote is specified this requires the HTTP server to be available (it will be started if possible: see startDynamicHelp).

One of the links on the index page is the HTML package index,
‘R.home("docs")/html/packages.html’, which can be remade by make.packages.html(). For
local operation, the HTTP server will remake a temporary version of this list when the link is first
clicked, and each time thereafter check if updating is needed (if .libPaths has changed or any of
the directories has been changed). This can be slow, and using update = TRUE will ensure that the
packages list is updated before launching the index page.

Argument remote can be used to point to HTML help published by another R installation: it will
typically only show packages from the main library of that installation.

See Also

help() for on- and off-line help in other formats.
browseURL for how the help file is displayed.
RSiteSearch to access an on-line search of R resources.

Examples

help.start()
## Not run:
## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))
## End(Not run)

hsearch-utils Help Search Utilities

Description

Utilities for searching the help system.

Usage

hsearch_db(package = NULL, lib.loc = NULL,
types = getOption("help.search.types"),
verbose = getOption("verbose"),
rebuild = FALSE, use_UTF8 = FALSE)
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())
Arguments

package a character vector with the names of packages to search through, or NULL in which case all available packages in the library trees specified by lib.loc are searched.

lib.loc a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

types a character vector listing the types of documentation to search. See help.search for details.

verbose a logical controlling the verbosity of building the help search database. See help.search for details.

rebuild a logical indicating whether the help search database should be rebuilt. See help.search for details.

use_UTF8 logical: should results be given in UTF-8 encoding?

db a help search database as obtained by calls to hsearch_db().

Details

hsearch_db() builds and caches the help search database for subsequent use by help.search. (In fact, re-builds only when forced (rebuild = TRUE) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual aliases, concepts and keywords together with the ids of the documentation objects they belong to. Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in help.search for how searchable entries are interpreted according to help type.

hsearch_db_concepts() and hsearch_db_keywords() extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

Examples

db <- hsearch_db()
## Total numbers of documentation objects, aliases, keywords and
classes (using the current format):
sapply(db, NROW)
## Can also be obtained from print method:
db
db ## 10 most frequent concepts:
head(hsearch_db_concepts(), 10)
## 10 most frequent keywords:
head(hsearch_db_keywords(), 10)
Install Add-on Packages

Description
Utility for installing add-on packages.

Usage
R CMD INSTALL [options] [-l lib] pkgs

Arguments
pkgs a space-separated list with the path names of the packages to be installed. See 'Details'.
lib the path name of the R library tree to install to. Also accepted in the form '-l=lib'. Paths including spaces should be quoted, using the conventions for the shell in use.
options a space-separated list of options through which in particular the process for building the help files can be controlled. Use R CMD INSTALL --help for the full current list of options.

Details
This will stop at the first error, so if you want all the pkgs to be tried, call this via a shell loop.

If used as R CMD INSTALL pkgs without explicitly specifying lib, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree lib, use R CMD INSTALL -l lib pkgs. This prepends lib to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both lib and the elements of pkgs may be absolute or relative path names of directories. pkgs may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by gzip, bzip2, xz or compress. Finally, binary package archive files (as created by R CMD INSTALL --build) can be supplied.

Tarballs are by default unpackaged by the internal untar function: if needed an external tar command can be specified by the environment variable R_INSTALL_TAR: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting R_INSTALL_TAR to 'tar.exe' has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by '--preclean' or after by '--clean': cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a 'configure' script that can be passed arguments or variables via the option '--configure-args' and '--configure-vars', respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables LIBS and CPPFLAGS to specify these locations (and set these via '--configure-vars'), see section ‘Configuration variables’ in “R Installation and Administration” for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option '--no-configure'.

Finally, binary package archive files (as created by R CMD INSTALL --build) can be supplied.

Tarballs are by default unpackaged by the internal untar function: if needed an external tar command can be specified by the envir...
If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section ‘Locking’ in the help for `install.packages`.

Option ‘--build’ can be used to tar up the installed package for distribution as a binary package (as used on macOS). This is done by `utils::tar` unless environment variable `R_INSTALL_TAR` is set.

By default a package is installed with static HTML help pages if and only if R was: use options ‘--no-html’ and ‘--html’ to override this.

Packages are not by default installed keeping the source formatting (see the keep.source argument to `source`): this can be enabled by the option ‘--with-keep.source’ or by setting environment variable `R_KEEP_PKG_SOURCE` to yes.

Use `R CMD INSTALL --help` for concise usage information, including all the available options.

### Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a 'src/Makefile' (or 'src/Makefile.win' on Windows), when only compiled code for the sub-architecture running `R CMD INSTALL` is installed.

To install a source package with compiled code only for the sub-architecture used by `R CMD INSTALL`, use ‘--no-multiarch’. To install just the compiled code for another sub-architecture, use ‘--libs-only’.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag ‘--force-biarch’ (and packages can specify this via a 'Biarch' field in their DESCRIPTION files). Second, a single tarball can be installed with

```bash
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

**Note**

The options do not have to precede 'pkgs' on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see `tempdir`, usually under ‘/tmp’) having both write and execution access to the account running R. This is usually the case, but if ‘/tmp’ has been mounted as noexec, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

**See Also**

`REMOVE`; `.libPaths` for information on using several library trees; `install.packages` for R-level installation of packages; `update.packages` for automatic update of packages using the Internet or a local repository.

install.packages

Install Packages from Repositories or Local Files

Description

Download and install packages from CRAN-like repositories or from local files.

Usage

install.packages(pkgs, lib, repos = getOption("repos"),
                  contriburl = contrib.url(repos, type),
                  method, available = NULL, destdir = NULL,
                  dependencies = NA, type = getOption("pkgType"),
                  configure.args = getOption("configure.args"),
                  configure.vars = getOption("configure.vars"),
                  clean = FALSE, Ncpus = getOption("Ncpus", 1L),
                  verbose = getOption("verbose"),
                  libs_only = FALSE, INSTALL_opts, quiet = FALSE,
                  keep_outputs = FALSE, ...)  

Arguments

pkgs character vector of the names of packages whose current versions should be
downloaded from the repositories.  
If repos = NULL, a character vector of file paths. These can be source direc-
tories or archives or binary package archive files (as created by R CMD build
--binary). (http:// and file:// URLs are also accepted and the files will be
downloaded and installed from local copies.) On a CRAN build of R for macOS
these can be ‘.tgz’ files containing binary package archives. Tilde-expansion
will be done on file paths.  
If this is missing or a zero-length character vector, a listbox of available packages
is presented where possible in an interactive R session.

lib character vector giving the library directories where to install the packages. Re-
cycled as needed. If missing, defaults to the first element of .libPaths().

repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a
CRAN mirror such as "https://cloud.r-project.org". For more details on
supported URL schemes see url.  
Can be NULL to install from local files, directories or URLs: this will be inferred
by extension from pkgs if of length one.

contriburl URL(s) of the contrib sections of the repositories. Use this argument if your
repository mirror is incomplete, e.g., because you burned only the ‘contrib’
section on a CD, or only have binary packages. Overrides argument repos.
Incompatible with type = "both".

method download method, see download.file. Unused if a non-NULL available is
supplied.

available a matrix as returned by available.packages listing packages available
at the repositories, or NULL when the function makes an internal call to
available.packages. Incompatible with type = "both".
destdir

directory where downloaded packages are stored. If it is NULL (the default) a subdirectory downloaded_packages of the session temporary directory will be used (and the files will be deleted at the end of the session).

dependencies

logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if repos = NULL. Can also be a character vector, a subset of c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances").

Only supported if lib is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.

The default, NA, means c("Depends", "Imports", "LinkingTo").

TRUE means to use c("Depends", "Imports", "LinkingTo", "Suggests") for pkgs and c("Depends", "Imports", "LinkingTo") for added dependencies: this installs all the packages needed to run pkgs, their examples, tests and vignettes (if the package author specified them correctly).

In all of these, "LinkingTo" is omitted for binary packages.

type

character, indicating the type of package to download and install. Will be "source" except on Windows and some macOS builds: see the section on 'Binary packages' for those.

configure.args

(Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to R CMD INSTALL. If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)

A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'.

configure.vars

(Used only for source installs.) Analogous to configure.args for flag '--configure-vars', which is used to set environment variables for the configure run.

clean

a logical value indicating whether to add the '--clean' flag to the call to R CMD INSTALL. This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.

Ncpus

the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by Sys.getenv("MAKE", "make") accepts argument -k -j Ncpus.

verbose

a logical indicating if some "progress report" should be given.

libs_only

a logical value: should the '--libs-only' option be used to install only additional sub-architectures for source installs? (See also INSTALL_opts.) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.

INSTALL_opts

an optional character vector of additional option(s) to be passed to R CMD INSTALL for a source package install. E.g., c("--html", "--no-multiarch", "--no-test-load").

Can also be a named list of character vectors to be used as additional options, with names the respective package names.
install.packages

quiet logical: if true, reduce the amount of output.

keep_outputs a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with ‘.out’ appended. Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files.

... Arguments to be passed to download.file or to the functions for binary installs on macOS and Windows (which accept an argument "lock": see the section on 'Locking').

Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in .libPaths(), with a message if there is more than one.) If lib is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of Sys.getenv("R_LIBS_USER")) and install there.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in lib are on the default library path for installs (set by environment variable R_LIBS).

You are advised to run update.packages before install.packages to ensure that any already installed dependencies have their latest versions.

Value

Invisible NULL.

Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for macOS.

R packages are primarily distributed as source packages, but binary packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for macOS. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of type are (currently) "source", "mac.binary", "mac.binary.el-capitan" and "win.binary": the appropriate binary type where supported can also be selected as "binary".

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

    options(install.packages.check.source = "no")

and should be if there is a partial repository containing only binary files.

An alternative (and the current default) is "both" which means 'use binary if available and current, otherwise try source’. The action if there are source packages which are preferred but may contain code which needs to be compiled is controlled by

    getOption("install.packages.compile.from.source"). type = "both" will be silently changed to "binary" if either contriburl or available is specified.

Using packages with type = "source" always works provided the package contains no C/C++/Fortran code that needs compilation. Otherwise, on macOS you need to have installed the ‘Command-line tools for Xcode’ (see the ‘R Installation and Administration Manual’) and if needed by the package a Fortran compiler, and have them in your path.
Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is ‘locked’ by creating a directory ‘00LOCK’ within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option ‘--pkglock’ which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when Ncpus > 1L. Finally locking (and restoration on error) can be suppressed by ‘--no-lock’.

For a macOS or Windows binary install, no locking is done by default. Setting argument lock to TRUE (it defaults to the value of getOption("install.lock", FALSE)) will use per-directory locking as described for source installs: if the value is "pkglock" per-package locking will be used.

If package locking is used on Windows with libs_only = TRUE and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for --pkglock, of the package) until the lock directory is removed manually.

Parallel installs

Parallel installs are attempted if pkgs has length greater than one and Ncpus > 1. It makes use of a parallel make, so the make specified (default make) when R was built must be capable of supporting make -j n: GNU make, dmake and pmake do, but Solaris make and older FreeBSD make do not: if necessary environment variable MAKE can be set for the current session to select a suitable make.

install.packages needs to be able to compute all the dependencies of pkgs from available, including if one element of pkgs depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, available needs to cover both CRAN and Bioconductor packages.

Timeouts

A limit on the elapsed time for each call to R CMD INSTALL (so for source installs) can be set via environment variable _R_INSTALL_PACKAGES_ELMAPSED_TIMEOUT_: in seconds (or in minutes or hours with optional suffix ‘m’ or ‘h’, suffix ‘s’ being allowed for the default seconds) with 0 meaning no limit.

For non-parallel installs this is implemented via the timeout argument of system2: for parallel installs via the OS’s timeout command. (The one tested is from GNU coreutils, commonly available on Linux but not other Unix-alikes. If no such command is available the timeout request is ignored, with a warning.) For parallel installs a ‘Error 124’ message from make indicates that timeout occurred.

Timeouts during installation might leave lock directories behind and not restore previous versions.

Note

Some binary distributions of R have INSTALL in a separate bundle, e.g. an R-devel RPM. install.packages will give an error if called with type = “source” on such a system.

Some binary Linux distributions of R can be installed on a machine without the tools needed to install packages: a possible remedy is to do a complete install of R which should bring in all those tools as dependencies.

The ‘R Installation and Administration’ manual for how to set up a repository.

Examples

## Not run:
## A Linux example for Fedora's layout of udunits2 headers.
install.packages(c("ncdf4", "RNetCDF"),
    configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))

## End(Not run)

 installed.packages  Find Installed Packages

Description

Find (or retrieve) details of all packages installed in the specified libraries.

Usage

installed.packages(lib.loc = NULL, priority = NULL,
    noCache = FALSE, fields = NULL,
    subarch = .Platform$r_arch, ...)

Arguments

lib.loc character vector describing the location of R library trees to search through, or
NULL for all known trees (see .libPaths).

priority character vector or NULL (default). If non-null, used to select packages; "high"
is equivalent to c("base", "recommended"). To select all packages without an
assigned priority use priority = "NA".

noCache Do not use cached information, nor cache it.

fields a character vector giving the fields to extract from each package’s DESCRIPTION
file in addition to the default ones, or NULL (default). Unavailable fields result in
NA values.

subarch character string or NULL. If non-null and non-empty, used to select packages
which are installed for that sub-architecture.

... allows unused arguments to be passed down from other functions.
isS3method

Is 'method' the Name of an S3 Method?

Description

Checks if method is the name of a valid / registered S3 method. Alternatively, when f and class are specified, it is checked if f is the name of an S3 generic function and paste(f, class, sep=".") is a valid S3 method.

Usage

isS3method(method, f, class, envir = parent.frame())
isS3stdGeneric

Check if a Function Acts as an S3 Generic

Description

Determines whether f acts as a standard S3-style generic function.

Usage

isS3stdGeneric(f)

Arguments

f A function object
Details

A closure is considered a standard S3 generic if the first expression in its body calls \( \text{UseMethod} \). Functions which perform operations before calling \( \text{UseMethod} \) will not be considered “standard” S3 generics.

Value

If \( f \) is an S3 generic, a logical vector containing TRUE with the name of the S3 generic (the string passed to \( \text{UseMethod} \)). Otherwise, FALSE (unnamed).

Description

Front-end for creating executable programs.

Usage

\[
\text{R CMD LINK [options] linkcmd}
\]

Arguments

- **linkcmd**: a list of commands to link together suitable object files (include library objects) to create the executable program.
- **options**: further options to control the linking, or for obtaining information about usage and version.

Details

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of \( \text{libtool} \) installed at \( \text{'R_HOME/bin'} \).

\[
\text{R CMD LINK --help}
\]
gives usage information.

Note

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

See Also

\( \text{COMPILE} \).
localeToCharset

Select a Suitable Encoding Name from a Locale Name

Description

This function aims to find a suitable coding for the locale named, by default the current locale, and
if it is a UTF-8 locale a suitable single-byte encoding.

Usage

localeToCharset(locale = Sys.getlocale("LC_CTYPE"))

Arguments

locale character string naming a locale.

Details

The operation differs by OS. Locale names are normally like es_MX.iso88591. If final component
indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name.
Otherwise, the language (here es) is used to choose a primary or fallback encoding.
In the C locale the answer will be "ASCII".

Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe
not with commercial Unixen.

See Also

Sys.getlocale, iconv.
Examples
localeToCharset()

ls.str

List Objects and their Structure

Description
ls.str and lsf.str are variations of ls applying str() to each matched name: see section Value.

Usage
ls.str(pos = -1, name, envir, all.names = FALSE, name, envir, all.names = FALSE, pattern, mode = "any")

lsf.str(pos = -1, envir, ...)

## S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ..., digits = max(1, getOption("str")$digits.d))

Arguments

pos integer indicating search path position, or -1 for the current environment.
name optional name indicating search path position, see ls.
envir environment to use, see ls.
all.names logical indicating if names which begin with a . are omitted; see ls.
pattern a regular expression passed to ls. Only names matching pattern are considered.
max.level maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.
give.attr logical; if TRUE (default), show attributes as sub structures.
mode character specifying the mode of objects to consider. Passed to exists and get.
x an object of class "ls_str".
... further arguments to pass. lsf.str passes them to ls.str which passes them on to ls. The (non-exported) print method print.ls_str passes them to str.
digits the number of significant digits to use for printing.

Value
ls.str and lsf.str return an object of class "ls_str", basically the character vector of matching names (functions only for lsf.str), similarly to ls, with a print() method that calls str() on each object.

Author(s)
Martin Maechler
See Also

str, summary, args.

Examples

```r
require(stats)

lsf.str()  # how do the functions look like which I am using?
ls.str(mode = "list")  # what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name ?
lsf.str(pos = length(search())), pattern = "file")

## demonstrating that ls.str() works inside functions
## "[browser/debug mode]"

## [browser/debug mode]:
tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2))," *: *"), \[\], 1))
stopifnot(nms == c("aa", "r", "x","y"))
```

Description

Show the name and email address of the maintainer of a package.

Usage

```r
maintainer(pkg)
```

Arguments

pkg Character string. The name of a single package.

Details

Accesses the package description to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the `bug.report` function.

Value

A character string giving the name and email address of the maintainer of the package, or NA if no such package is installed.
Author(s)

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

References

packageDescription, bug.report

Examples

maintainer("MASS")

make.packages.html

Update HTML Package List

Description

Re-create the HTML list of packages.

Usage

make.packages.html(lib.loc = .libPaths(), temp = FALSE, verbose = TRUE, docdir = R.home("doc"))

Arguments

lib.loc character vector. List of libraries to be included.
temp logical: should the package indices be created in a temporary location for use by the HTTP server?
verbose logical. If true, print out a message.
docdir If temp is false, directory in whose ‘html’ directory the ‘packages.html’ file is to be created/updated.

Details

This creates the ‘packages.html’ file, either a temporary copy for use by help.start, or the copy in ‘R.home("doc")/html’ (for which you will need write permission).

It can be very slow, as all the package ‘DESCRIPTION’ files in all the library trees are read.

For temp = TRUE there is some caching of information, so the file will only be re-created if lib.loc or any of the directories it lists have been changed.

Value

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable permissions.
See Also

help.start

Examples

## Not run:
make.packages.html()
# this can be slow for large numbers of installed packages.

## End(Not run)

make.socket  
Create a Socket Connection

Description

With \texttt{server = FALSE} attempts to open a client socket to the specified port and host. With \texttt{server = TRUE} the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use \texttt{on.exit} to ensure that a socket is closed, as you only get 64 of them.

Usage

\texttt{make.socket(host = "localhost", port, fail = TRUE, server = FALSE)}

Arguments

\texttt{host}  
name of remote host

\texttt{port}  
port to connect to/listen on

\texttt{fail}  
failure to connect is an error?

\texttt{server}  
a server socket?

Value

An object of class "socket", a list with components:

\texttt{socket}  
socket number. This is for internal use. On a Unix-alike it is a file descriptor.

\texttt{port}  
port number of the connection.

\texttt{host}  
name of remote computer.

Warning

I don't know if the connecting host name returned when \texttt{server = TRUE} can be trusted. I suspect not.

Author(s)

Thomas Lumley
References

Adapted from Luke Tierney’s code for XLISP-Stat, in turn based on code from Robbins and Robbins “Practical UNIX Programming”.

See Also

close.socket, read.socket.

Compiling in support for sockets was optional prior to R 3.3.0: see capabilities("sockets") to see if it is available.

Examples

daytime <- function(host = "localhost"){  
a <- make.socket(host, 13)  
on.exit(close.socket(a))  
read.socket(a)  
}  
## Official time (UTC) from US Naval Observatory  
## Not run: daytime("tick.usno.navy.mil")

memory.size

Report on Memory Allocation

Description

memory.size and memory.limit are used to manage the total memory allocation on Windows. On other platforms these are stubs which report infinity with a warning.

Usage

memory.size(max = FALSE)

memory.limit(size = NA)

Arguments

max       logical. If true the maximum amount of memory obtained from the OS is reported, otherwise the amount currently in use.
size      numeric. If NA report the memory size, otherwise request a new limit, in Mb.

Details

To restrict memory usage on a Unix-alike use the facilities of the shell used to launch R, e.g. limit or ulimit.

Value

Size in bytes: always Inf.

See Also

Memory-limits for other limits.
Menu Interaction Function

Description

`menu` presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select ‘0’.

Usage

```r
menu(choices, graphics = FALSE, title = NULL)
```

Arguments

- `choices`: a character vector of choices
- `graphics`: a logical indicating whether a graphics menu should be used if available.
- `title`: a character string to be used as the title of the menu. `NULL` is also accepted.

Details

If `graphics = TRUE` and a windowing system is available (Windows, macOS or X11 via Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use `menu` in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is `NULL` or `""`.

Value

The number corresponding to the selected item, or 0 if no choice was made.

References

See Also

- `select.list`, which is used to implement the graphical menu, and allows multiple selections.

Examples

```r
## Not run:
switch(menu(c("List letters", "List LETTERS")== 1, 
cat("Nothing done\n"), letters, LETTERS)
## End(Not run)
```
methods

List Methods for S3 Generic Functions or Classes

Description
List all available methods for a S3 and S4 generic function, or all methods for an S3 or S4 class.

Usage
methods(generic.function, class)
.S3methods(generic.function, class, envir=parent.frame())

## S3 method for class 'MethodsFunction'
print(x, byclass = attr(x, "byclass"), ...)  

Arguments

- **generic.function**: a generic function, or a character string naming a generic function.
- **class**: a symbol or character string naming a class: only used if generic.function is not supplied.
- **envir**: the environment in which to look for the definition of the generic function, when the generic function is passed as a character string.
- **x**: typically the result of methods(...), an R object of class "MethodsFunction", see 'Value' below.
- **byclass**: an optional logical allowing to override the "byclass" attribute determining how the result is printed, see ‘Details’.
- **...**: potentially further arguments passed to and from methods; unused currently.

Details
methods() finds S3 and S4 methods associated with either the generic.function or class argument. Methods are found in all packages on the current search() path. .S3methods() finds only S3 methods, .S4methods() finds only only S4 methods.

When invoked with the generic.function argument, the "byclass" attribute (see Details) is FALSE, and the print method by default displays the signatures (full names) of S3 and S4 methods. S3 methods are printed by pasting the generic function and class together, separated by a ".", as generic.class. The S3 method name is followed by an asterisk * if the method definition is not exported from the package namespace in which the method is defined. S4 method signatures are printed as generic,class-method; S4 allows for multiple dispatch, so there may be several classes in the signature generic,A,B-method.

When invoked with the class argument, "byclass" is TRUE, and the print method by default displays the names of the generic functions associated with the class, generic.

The source code for all functions is available. For S3 functions exported from the namespace, enter the method at the command line as generic.class. For S3 functions not exported from the namespace, see getAnywhere or getS3method. For S4 methods, see getMethod.

Help is available for each method, in addition to each generic. For interactive help, use the documentation shortcut ? with the name of the generic and tab completion, ?"generic<tab>" to select the method for which help is desired.
The S3 functions listed are those which are named like methods and may not actually be methods (known exceptions are discarded in the code).

**Value**

An object of class "MethodsFunction", a character vector of method names with "byclass" and "info" attributes. The "byclass" attribute is a logical indicating if the results were obtained with argument class defined. The "info" attribute is a data frame with columns:

- **generic** character vector of the names of the generic.
- **visible** logical(), is the method exported from the namespace of the package in which it is defined?
- **isS4** logical(), true when the method is an S4 method.
- **from** a factor, the location or package name where the method was found.

**Note**

The original methods function was written by Martin Maechler.

**References**

**See Also**

S3Methods, class, getS3method.

For S4, getMethod, showMethods, Introduction or Methods_Details.

**Examples**

```r
require(stats)
methods(summary)
methods(class = "aov")  # S3 class
## The same, with more details and more difficult to read:
print(methods(class = "aov"), byclass=FALSE)
methods("["   )  # uses C-internal dispatching
methods("$")
methods("$<-")  # replacement function
methods("+")   # binary operator
methods("Math") # group generic
require(graphics)
methods("axis")  # looks like a generic, but is not

if(require(Matrix)) {
  print(methods(class = "Matrix"))  # S4 class
  m <- methods("dim")  # S3 and S4 methods
  print(m)
  print(attr(m, "info"))  # more extensive information

  ## --> help(showMethods) for related examples
}
```
mirrorAdmin

Managing Repository Mirrors

Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

Usage

```
mirror2html(mirrors = NULL, file = "mirrors.html",
            head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)
```

Arguments

- `mirrors`: A data frame, by default the CRAN list of mirrors is used.
- `file`: A connection or a character string.
- `head`: Name of optional header file.
- `foot`: Name of optional footer file.
- `method`: Download method, see `download.file`.

Details

- `mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.
- `checkCRAN` performs a sanity checks on all CRAN mirrors.

modifyList

Recursively Modify Elements of a List

Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

Usage

```
modifyList(x, val, keep.null = FALSE)
```

Arguments

- `x`: A named list, possibly empty.
- `val`: A named list with components to replace corresponding components in `x`.
- `keep.null`: If TRUE, NULL elements in `val` become NULL elements in `x`. Otherwise, the corresponding element, if present, is deleted from `x`. 
A modified version of \( x \), with the modifications determined as follows (here, list elements are identified by their names). Elements in \( \text{val} \) which are missing from \( x \) are added to \( x \). For elements that are common to both but are not both lists themselves, the component in \( x \) is replaced (or possibly deleted, depending on the value of \( \text{keep.null} \)) by the one in \( \text{val} \). For common elements that are in both lists, \( x[\text{name}] \) is replaced by \( \text{modifyList}(x[\text{name}], \text{val}[\text{name}]) \).

Author(s)

Deepayan Sarkar &lt;Deepayan.Sarkar@R-project.org&gt;

Examples

\[
\begin{align*}
\text{foo} &\leftarrow \text{list}(a = 1, b = \text{list}(c = \text{"a"}, d = \text{FALSE})) \\
\text{bar} &\leftarrow \text{modifyList}(\text{foo}, \text{list}(e = 2, b = \text{list}(d = \text{TRUE}))) \\
\text{str}(\text{foo}) \\
\text{str}(\text{bar})
\end{align*}
\]

Description

Build and query the news data base for \( \text{R} \) or add-on packages.

Usage

\[
\begin{align*}
\text{news}(\text{query}, \text{package} = \text{"R"}, \text{lib.loc} = \text{NULL}, \text{format} = \text{NULL}, \\
&\text{reader} = \text{NULL}, \text{db} = \text{NULL}) \\
\end{align*}
\]

## S3 method for class 'news_db'

\text{print}(x, \text{doBrowse} = \text{interactive}(), \\
&\text{browser} = \text{getOption("browser"), ...})

Arguments

- \text{query} 
  an expression for selecting news entries
- \text{package} 
  a character string giving the name of an installed add-on package, or "\( \text{R} \)".
- \text{lib.loc} 
  a character vector of directory names of \( \text{R} \) libraries, or \text{NULL}. The default value of \text{NULL} corresponds to all libraries currently known.
- \text{format} 
  Not yet used.
- \text{reader} 
  Not yet used.
- \text{db, x} 
  a news db obtained from \text{news}()
- \text{doBrowse} 
  logical specifying that the news should be opened in the browser (by \text{browseURL}, accessible as via \text{help.start}) instead of printed to the console.
- \text{browser} 
  the browser to be used, see \text{browseURL}.
- \text{...} 
  potentially further arguments passed to \text{print}().
Details

If package is "R" (default), a news db is built with the news since the 3.0.0 release of R (corresponding to R’s top-level ‘NEWS’ file). Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files ‘inst/NEWS.Rd’, ‘NEWS’ or ‘inst/NEWS’ (in that order).

File ‘inst/NEWS.Rd’ should be an Rd file given the entries as Rd\itemize lists, grouped according to version using section elements with names starting with a suitable prefix (e.g. “Changes in version” followed by a space and the version number, and optionally followed by a space and a parenthesized ISO 8601 (%Y-%m-%d, see \texttt{strptime}) format date, and possibly further grouped according to categories using \texttt{\section}[..] elements named as the categories. At the very end of \texttt{\section}[..], the date may also be specified as (%Y-%m-%d, <note>), i.e., including parentheses.

The plain text ‘NEWS’ files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header “Changes in version” at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of ‘o’, ‘*’, ‘-’ or ‘+’ as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Additional formats and readers may be supported in the future.

Package \texttt{tools} provides an (internal) utility function \texttt{news2Rd} to convert plain text ‘NEWS’ files to Rd. For ‘NEWS’ files in a format which can successfully be handled by the default reader, package maintainers can use \texttt{tools:::news2Rd(dir, "NEWS.Rd")}, possibly with additional argument \texttt{codify = TRUE}, with \texttt{dir} a character string specifying the path to a package’s root directory. Upon success, the ‘NEWS.Rd’ file can further be improved and then be moved to the ‘inst’ subdirectory of the package source directory.

The news db built is a character data frame inheriting from “news_db” with variables Version, Category, Date and Text, where the last contains the entry texts read, and the other variables may be NA if they were missing or could not be determined.

Using \texttt{query}, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, \texttt{query} should be an expression involving (a subset of) the variables Version, Category, Date and Text, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave \texttt{TRUE} are selected. When evaluating, Version and Date are coerced to \texttt{numeric_version} and \texttt{Date} objects, respectively, so that the comparison operators for these classes can be employed.

Value

A data frame inheriting from class "news_db", with attributes "package" (and "subset" if the query lead to proper subsetting).

Examples

```r
## Build a db of all R news entries.
db <- news()

## Bug fixes with PR number in 3.0.1.
```
db3 <- news(Version == "3.0.1" & grepl("^BUG", Category) & grepl("PR#", Text),
db = db)

## News from a date range ('Matrix' is there in a regular R installation):
if(length(iM <- find.package("Matrix", quiet=TRUE)) & nzchar(iM)) {
  dM <- news(package="Matrix")
  stopifnot(identical(dM, news(db=dM)))
  dM2014 <- news("2014-01-01" <= Date & Date <= "2014-12-31", db = dM)
  stopifnot(paste0("1.1-", 2:4) %in% dM2014[,"Version"])
}

## Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)

## Entries with version >= 3.0.0 (including "3.0.0 patched"):
table(news(Version >= "3.0.0", db = db)$Version)

---

**nsl**

*Look up the IP Address by Hostname*

**Description**

Interface to gethostbyname.

**Usage**

```
nsl(hostname)
```

**Arguments**

- `hostname` the name of the host.

**Details**

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file ‘arpa/inet.h’. This function is not available on Windows.

**Value**

The IP address, as a character string, or NULL if the call fails.

**Examples**

```
## Not run: nsl("www.r-project.org")
```
object.size

Report the Space Allocated for an Object

Description

Provides an estimate of the memory that is being used to store an R object.

Usage

object.size(x)

## S3 method for class 'object_size'
format(x, units = "b", standard = "auto", digits = 1L, ...)

## S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", standard = "auto", digits = 1L, ...)

Arguments

x

an R object.

quote

logical, indicating whether or not the result should be printed with surrounding quotes.

units

the units to be used in formatting and printing the size. Allowed values for the different standards are

standard = "SI": "B", "kB", "MB", "GB", "TB", "PB", "EB", "ZB" and "YB".

For all standards, unit = "auto" is also allowed. If standard = "auto", any of the "legacy" and IEC units are allowed. See ‘Formatting and printing object sizes’ for details.

standard

the byte-size unit standard to be used. A character string, possibly abbreviated from "legacy", "IEC", "SI" and "auto". See ‘Formatting and printing object sizes’ for details.

digits

the number of digits after the decimal point, passed to round.

... arguments to be passed to or from other methods.

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a EXTPTRSXP points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.
Value

An object of class "object.size" with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

Formatting and printing object sizes

Object sizes can be formatted using byte-size units from R’s legacy standard, the IEC standard, or the SI standard. As illustrated by below tables, the legacy and IEC standards use binary units (multiples of 1024), whereas the SI standard uses decimal units (multiples of 1000).

For methods format and print, argument standard specifies which standard to use and argument units specifies which byte-size unit to use. units = "auto" chooses the largest units in which the result is one or more (before rounding). Byte sizes are rounded to digits decimal places. standard = "auto" chooses the standard based on units, if possible, otherwise, the legacy standard is used.

Summary of R’s legacy and IEC units:

<table>
<thead>
<tr>
<th>object size</th>
<th>legacy</th>
<th>IEC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1 bytes</td>
<td>1 B</td>
</tr>
<tr>
<td>1024</td>
<td>1 Kb</td>
<td>1 KiB</td>
</tr>
<tr>
<td>1024^2</td>
<td>1 Mb</td>
<td>1 MiB</td>
</tr>
<tr>
<td>1024^3</td>
<td>1 Gb</td>
<td>1 GiB</td>
</tr>
<tr>
<td>1024^4</td>
<td>1 Tb</td>
<td>1 TiB</td>

package.skeleton

Create a Skeleton for a New Source Package

Description

package.skeleton automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

Usage

package.skeleton(name = "anRpackage", list, environment = .GlobalEnv, path = ".", force = FALSE, code_files = character(), encoding = "unknown")

Arguments

name character string: the package name and directory name for your package.
list character vector naming the R objects to put in the package. Usually, at most one of list, environment, or code_files will be supplied. See ‘Details’.
environment an environment where objects are looked for. See ‘Details’.

See Also

Memory-limits for the design limitations on object size.

Examples

object.size(letters)
object.size(ls)
format(object.size(library), units = "auto")

sl <- object.size(rep(letters, 1000))

print(sl) ## 209288 bytes
print(sl, units = "auto") ## 204.4 Kb
print(sl, units = "auto", standard = "IEC") ## 204.4 KiB
print(sl, units = "auto", standard = "SI") ## 209.3 kB

(fsl <- sapply(c("Kb", "KB", "KiB"),
    function(u) format(sl, units = u)))

stopifnot(identical( ## assert that all three are the same :
    unique(substr(as.vector(fsl), 1,5)),
    format(round(as.vector(sl)/1024, 1))))

## find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
    object.size(get(x, envir = baseenv())))
if(interactive()) {
    as.matrix(rev(sort(z))[1:10])
} else # (more constant over time):
    names(rev(sort(z))[1:10])
package.skeleton

path

path to put the package directory in.

force

If FALSE will not overwrite an existing directory.

code_files

a character vector with the paths to R code files to build the package around. See ‘Details’.

encoding

optionally a character string with an encoding for an optional Encoding: line in ‘DESCRIPTION’ when non-ASCII characters will be used; typically one of "latin1", "latin2", or "UTF-8"; see the WRE manual.

Details

The arguments list, environment, and code_files provide alternative ways to initialize the package. If code_files is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise list defaults to the objects in environment (including those whose names start with .), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the prompt, promptClass, and promptMethods functions. If an object from another package is intended to be imported and re-exported without changes, the promptImport function should be used after package.skeleton to generate a simple help file linking to the original one.

The package sources are placed in subdirectory name of path. If code_files is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in code_files should have suffix ".R" and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by ‘_’, invalid names are preceded by ‘zz’, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by make.unique(sep = "_"). This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary z prepended.

Functions with names starting with a dot are placed in file ‘R/name-internal.R’.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

Value

Used for its side-effects.

References

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a source package you need to install it: see the ‘R Installation and Administration’ manual, INSTALL and install.packages.

See Also

prompt, promptClass, and promptMethods.

package_native_routine_registration_skeleton for helping in preparing packages with compiled code.
Examples

```r
require(stats)
## two functions and two "data sets" :
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)
package.skeleton(list = c("f","g","d","e"), name = "mypkg")
```

### Description

Parses and returns the `DESCRIPTION` file of a package as a "packageDescription".
Utility functions return (transformed) parts of that.

### Usage

```r
packageDescription(pkg, lib.loc = NULL, fields = NULL, drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
packageDate(pkg, lib.loc = NULL, date.fields = c("Date", "Packaged", "Date/Publication", "Built"), tryFormats = c("%Y-%m-%d", "%Y/%m/%d", "%d", "%m/%d/%y"), desc = packageDescription(pkg, lib.loc=lib.loc, fields=date.fields))
asDateBuilt(built)
```

### Arguments

- **pkg**
  - a character string with the package name.

- **lib.loc**
  - a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages and namespaces are searched before the libraries.

- **fields**
  - a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).

- **drop**
  - If TRUE and the length of fields is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".

- **encoding**
  - If there is an Encoding field, to what encoding should re-encoding be attempted? If NA, no re-encoding. The other values are as used by iconv, so the default "" indicates the encoding of the current locale.

- **date.fields**
  - character vector field tags to be tried. The first for which as.Date(.) is not NA will be returned.

- **tryFormats**
  - date formats to try, see as.Date.character().

- **desc**
  - optionally, a named list with components named from date.fields; where the default is fine, a complete packageDescription() maybe specified as well.

- **built**
  - for asDateBuilt(), a character string as from packageDescription(*, fields="Built").
Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid Version field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An attached environment named to look like a package (e.g., package:utils2) will be ignored.

packageVersion() is a convenience shortcut, allowing things like
if (packageVersion("MASS") < "7.3") { do.things }.

For packageDate(), if desc is valid, both pkg and lib.loc are not made use of.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, packageDescription returns an object of class "packageDescription", which is a named list with the values of the (given) fields as elements and the tags as names, unless drop = TRUE.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if fields is not null, and NA otherwise.

packageVersion() returns a (length-one) object of class "package_version".

packageDate() will return a “Date” object from as.Date() or NA.

asDateBuilt(built) returns a “Date” object or signals an error if built is invalid.

See Also

read.dcf

Examples

packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)

if(packageVersion("MASS") < "7.3.29")
message("you need to update MASS")

pu <- packageDate("utils")
str(pu)
stopifnot(identical(pu, packageDate(desc = packageDescription("utils"))),
identical(pu, packageDate("stats"))) # as "utils" and "stats" are # both 'base R' and "Built" at same time

packageName

Find Package Associated with an Environment

Description

Many environments are associated with a package; this function attempts to determine that package.

Usage

packageName(env = parent.frame())
packageStatus

Arguments

env

The environment whose name we seek.

Details

Environment env would be associated with a package if `topenv(env)` is the namespace environment for that package. Thus when env is the environment associated with functions inside a package, or local functions defined within them, `packageName` will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. `packageName` will return NULL in these cases.

Value

A length one character vector containing the name of the package, or NULL if there is no name.

See Also

`getPackageName` is a more elaborate function that can construct a name if none is found.

Examples

```r
packageName()
packageName(environment(mean))
```

---

packageStatus Package Management Tools

Description

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

Usage

```r
packageStatus(lib.loc = NULL, repositories = NULL, method, type = getOption("pkgType"), ...)
```

```r
## S3 method for class 'packageStatus'
summary(object, ...)
```

```r
## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath), repositories = levels(object$avail$Repository), ...)
```

```r
## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)
```
packageStatus

Arguments

lib.loc      a character vector describing the location of R library trees to search through, or
            NULL. The default value of NULL corresponds to all libraries currently known.
repositories  a character vector of URLs describing the location of R package repositories
            on the Internet or on the local machine. If specified as NULL, derive appropriate
            URLs from option "repos".
method       Download method, see download.file.
type         type of package distribution: see install.packages.
object       an object of class "packageStatus" as returned by packageStatus.
ask          if TRUE, the user is prompted which packages should be upgraded and which
            not.
...          for packageStatus: arguments to be passed to available.packages and
            installed.packages.
            for the upgrade method, arguments to be passed to install.packages
            for other methods: currently not used.

Details

The URLs in repositories should be full paths to the appropriate contrib sections of the reposi-
atories. The default is contrib.url(getOption("repos")),

There are print and summary methods for the "packageStatus" objects: the print method gives
a brief tabular summary and the summary method prints the results.

The update method updates the "packageStatus" object. The upgrade method is similar to
update.packages: it offers to install the current versions of those packages which are not cur-
rently up-to-date.

Value

An object of class "packageStatus". This is a list with two components

inst         a data frame with columns as the matrix returned by installed.packages plus
            "Status", a factor with levels c("ok", "upgrade", "unavailable"). Only
            the newest version of each package is reported, in the first repository in which it
            appears.
avail        a data frame with columns as the matrix returned by available.packages plus
            "Status", a factor with levels c("installed", "not installed").

For the summary method the result is also of class "summary.packageStatus" with additional
components

Libs          a list with one element for each library
Repos         a list with one element for each repository

with the elements being lists of character vectors of package name for each status.

installed.packages, available.packages
Invoke a Pager on an R Object

Displays a representation of the object named by \texttt{x} in a pager via \texttt{file.show}.

**Usage**

\begin{verbatim}
page(x, method = c("dput", "print"), ...)
\end{verbatim}

**Arguments**

- \texttt{x}: An \texttt{R} object, or a character string naming an object.
- \texttt{method}: The default method is to dump the object via \texttt{dput}. An alternative is to use \texttt{print} and capture the output to be shown in the pager. Can be abbreviated.
- \texttt{...}: Additional arguments for \texttt{dput, print} or \texttt{file.show} (such as \texttt{title}).

**Details**

If \texttt{x} is a length-one character vector, it is used as the name of an object to look up in the environment from which \texttt{page} is called. All other objects are displayed directly.

A default value of \texttt{title} is passed to \texttt{file.show} if one is not supplied in \texttt{...}.

**See Also**

- \texttt{file.show, edit, fix}

To go to a new page when graphing, see \texttt{frame}.

**Examples**

\begin{verbatim}
## Not run: # four ways to look at the code of 'page'
page(page)  # as an object
page("page") # a character string
v <- "page"; page(v) # a length-one character vector
page(utils::page) # a call

## End(Not run)
\end{verbatim}
Description

A class and utility methods for holding information about persons like name and email address.

Usage

```r
person(given = NULL, family = NULL, middle = NULL,
       email = NULL, role = NULL, comment = NULL,
       first = NULL, last = NULL)
```

## Default S3 method:

```r
as.person(x)
```

## S3 method for class 'person'

```r
format(x,  
       include = c("given", "family", "email", "role", "comment"),  
       braces = list(given = "", family = "", email = c("<", ", ">"),  
                     role = c("[", "]"), comment = c("(" ", ")")),  
       collapse = list(given = " ", family = " ", email = ", ",  
                         role = ", ", comment = ", "),  
....  
       style = c("text", "R")
)
```

Arguments

- **given**: a character vector with the *given* names, or a list thereof.
- **family**: a character string with the *family* name, or a list thereof.
- **middle**: a character string with the collapsed middle name(s). Deprecated, see Details.
- **email**: a character string (or vector) giving an e-mail address (each), or a list thereof.
- **role**: a character vector specifying the role(s) of the person (see Details), or a list thereof.
- **comment**: a character string (or vector) providing comments, or a list thereof.
- **first**: a character string giving the first name. Deprecated, see Details.
- **last**: a character string giving the last name. Deprecated, see Details.
- **x**: a character string for the as.person default method; an object of class "person" otherwise.
- **include**: a character vector giving the fields to be included when formatting.
- **braces**: a list of characters (see Details).
- **collapse**: a list of characters (see Details).
- **...**: currently not used.
- **style**: a character string specifying the print style, with "R" yielding formatting as R code.
Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to `person()` with list arguments, or by first creating objects representing single persons and combining these via `c()`.

The `format()` method collapses information about persons into character vectors (one string for each person): the fields in include are selected, each collapsed to a string using the respective element of collapse and subsequently “embraced” using the respective element of braces, and finally collapsed into one string separated by white space. If braces and/or collapse do not specify characters for all fields, the defaults shown in the usage are imputed. If collapse is `FALSE` or `NA` the corresponding field is not collapsed but only the first element is used. The `print()` method calls the `format()` method and prints the result, the `toBibtex()` method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using `$`) or by position (using `[`).

`as.person()` is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., [https://en.wikipedia.org/wiki/Personal_name](https://en.wikipedia.org/wiki/Personal_name).

The current implementation (starting from R 2.12.0) of the "person" class uses the notions of given (including middle names) and family names, as specified by `given` and `family` respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments `first`, `middle` and `last` are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments. For persons which are not natural persons (e.g., institutions, companies, etc.) it is appropriate to use `given` (but not `family`) for the name, e.g., `person("R Core Team", role = "aut").`

The new scheme also adds the possibility of specifying roles based on a subset of the MARC Code List for Relators ([https://www.loc.gov/marc/relators/relaterm.html](https://www.loc.gov/marc/relators/relaterm.html)). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.
"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.
"cph" (Copyright holder) Use for all copyright holders.
"cre" (Creator) Use for the package maintainer.
"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.
"ctr" (Contractor) Use for authors who have been contracted to write (parts of) the package and hence do not own intellectual property.
"dtc" (Data contributor) Use for persons who contributed data sets for the package.
"fnd" (Funder) Use for persons or organizations that furnished financial support for the development of the package.
"rev" (Reviewer) Use for persons or organizations responsible for reviewing (parts of) the package.
"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.
"tr1" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.
In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator personList() for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the personList mechanism.

The comment field can be used for “arbitrary” additional information about persons. Elements named "ORCID" will be taken to give ORCID identifiers (see https://orcid.org/ for more information), and be displayed as the corresponding URIs by the print() and format() methods (see Examples below).

Value

person() and as.person() return objects of class "person".

Examples

## Create a person object directly ...
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")

## ... or convert a string.
p2 <- as.person("Ronald Aylmer Fisher")

## Combining and subsetting.
p <- c(p1, p2)
p[1]
p[-1]

## Extracting fields.
p$family
p$email
p[1]$email

## Specifying package authors, example from "boot":
## AC is the first author [aut] who wrote the S original.
## BR is the second author [aut], who translated the code to R [trl],
## and maintains the package [cre].
b <- c(person("Angelo", "Canty", role = "aut", comment =
person(c("Brian", "D."). "Ripley", role = c("aut", "trl", "cre"),
   comment = "R port", email = "ripley@stats.ox.ac.uk"))

b

## Formatting.
format(b)

format(b, include = c("family", "given", "role"),
   braces = list(family = c("", ","), role = c("(Role(s): ", ")"))

## Conversion to BibTeX author field.
paste(format(b, include = c("given", "family")), collapse = " and ")
toBibtex(b)

## ORCID identifiers.
(p3 <- person("Achim", "Zeileis",
  comment = c(ORCID = "0000-0003-0918-3766")))

**Description**

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source package from them.

**Usage**

```
R CMD check [options] pkgdirs
R CMD build [options] pkgdirs
```

**Arguments**

- `pkgdirs` a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension `.tar.gz`, `.tgz`, `.tar.bz2` or `.tar.xz`.
- `options` further options to control the processing, or for obtaining information about usage and version of the utility.

**Details**

**R CMD check** checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

**R CMD build** builds R source tarballs. The name(s) of the packages are taken from the `DESCRIPTION` files and not from the directory names. This works entirely on a copy of the supplied source directories.

Use **R CMD foo --help** to obtain usage information on utility `foo`.

The defaults for some of the options to **R CMD build** can be set by environment variables `R_BUILD_RESAVE_DATA` and `R_BUILD_COMPACT_VIGNETTES`: see 'Writing R Extensions'. Many of the checks in **R CMD check** can be turned off or on by environment variables: see Chapter 6 of the 'R Internals' manual.

By default **R CMD build** uses the "internal" option to `tar` to prepare the tarball. An external `tar` program can be specified by the `R_BUILD_TAR` environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

**R CMD check** by default unpacks tarballs by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `"tar.exe"` has been needed to overcome permissions issues on some Windows systems.)

The sections on “Checking and building packages” and “Processing Rd format” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).
process.events  

**Trigger Event Handling**

**Description**

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The `process.events` function does that.

**Usage**

```r
process.events()
```

**Details**

This is a simple wrapper for the C API function `R_ProcessEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

**Value**

NULL is returned invisibly.

---

**prompt**  

**Produce Prototype of an R Documentation File**

**Description**

Facilitate the constructing of files documenting R objects.

**Usage**

```r
prompt(object, filename = NULL, name = NULL, ...)
```

### Default S3 method:

```r
prompt(object, filename = NULL, name = NULL, force.function = FALSE, ...)
```

### S3 method for class 'data.frame'

```r
prompt(object, filename = NULL, name = NULL, ...)
```

```r
promptImport(object, filename = NULL, name = NULL, importedFrom = NULL, importPage = name, ...)
```
Arguments

- **object**: an R object, typically a function for the default method. Can be `missing` when name is specified.
- **filename**: usually, a `connection` or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is `name` followed by ".Rd". Can also be NA (see below).
- **name**: a character string specifying the name of the object.
- **force.function**: a logical. If `TRUE`, treat `object` as function in any case.
- **...**: further arguments passed to or from other methods.
- **importedFrom**: a character string naming the package from which `object` was imported. Defaults to the environment of `object` if `object` is a function.
- **importPage**: a character string naming the help page in the package from which `object` was imported.

Details

Unless `filename` is NA, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the 'man' subdirectory of the package containing the object to be documented.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

When `prompt` is used in `for` loops or scripts, the explicit name specification will be useful.

The `importPage` argument for `promptImport` needs to give the base of the name of the help file of the original help page. For example, the `approx` function is documented in ‘`approxfun.Rd`’ in the `stats` package, so if it were imported and re-exported it should have `importPage = "approxfun"`. Objects that are imported from other packages are not normally documented unless re-exported.

Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

The default `filename` may not be a valid filename under limited file systems (e.g., those on Windows).

Currently, calling `prompt` on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use `promptData` to create documentation skeletons for data sets.

Note

The documentation file produced by `prompt.data.frame` does not have the same format as many of the data frame documentation files in the `base` package. We are trying to settle on a preferred format for the documentation.

Author(s)

Douglas Bates for `prompt.data.frame`
promptData

Generate Outline Documentation for a Data Set

Description

Generates a shell of documentation for a data set.

Usage

promptData(object, filename = NULL, name = NULL)

Arguments

object an R object to be documented as a data set.
filename usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).
name a character string specifying the name of the object.

Examples

require(graphics)
prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")

prompt(women) # data.frame
unlink("women.Rd")

prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")

## Not run:
## Create a help file for each function in the .GlobalEnv:
for(f in ls()) if(is.function(get(f))) prompt(name = f)
## End(Not run)
.promptPackage

Generate a Shell for Documentation of a Package

Description

Generates a shell of documentation for an installed or source package.

Usage

promptPackage(package, lib.loc = NULL, filename = NULL, name = NULL, final = FALSE)

Arguments

package  
a character string with the name of an installed or source package to be documented.

lib.loc  
a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known. For a source package this should specify the parent directory of the package’s sources.

filename  
usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).

name  
a character string specifying the name of the help topic, typically of the form ‘<pkg>-package’.

final  
a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.

Details

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

Currently, only data frames are handled explicitly by the code.

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

See Also

prompt

Examples

promptData(sunspots)
unlink("sunspots.Rd")
Details

Unless filename is NA, a documentation shell for package is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n"), where x is the list-style representation.

If final is TRUE, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but final = TRUE is certainly less work).

Value

If filename is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

prompt, package.skeleton

Examples

```r
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

Description

These functions provide access to documentation. Documentation on a topic with name name (typically, an R object or a data set) can be displayed by either help("name") or ?name.

Usage

```r
?topic

type?topic
```

Arguments

- **topic** Usually, a name or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls `pkg::topic` and `pkg:::topic` are treated specially, and look for help on topic in package pkg.

- **type** the special type of documentation to use for this topic; for example, if the type is class, documentation is provided for the class with name topic. See the Section 'S4 Method Documentation' for the uses of type to get help on formal methods, including methods?function and method?call.
Details

This is a shortcut to help and uses its default type of help.

Some topics need to be quoted (by backticks) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow reserved words (including if, else for, in, repeat, while, break and next. The other reserved words can be used as if they were names, for example TRUE, NA and Inf.

S4 Method Documentation

Authors of formal (‘S4’) methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The "?" operator allows access to this documentation in three ways.

The expression methods?f will look for the overall documentation methods for the function f. Currently, this means the documentation file containing the alias f-methods.

There are two different ways to look for documentation on a particular method. The first is to supply the topic argument in the form of a function call, omitting the type argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The "?" operator can also be called with doc_type supplied as method; in this case also, the topic argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using selectMethod (see the documentation for getMethod). A limitation is that methods in packages (as opposed to regular functions) will only be found if the package exporting them is on the search list, even if it is specified explicitly using the ?package::generic() notation.

## Not run:
### Description

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

### Usage

```r
rc.settings(ops, ns, args, func, ipck, S3, data, help, argdb, fuzzy, quotes, files)
rc.status()
rc.options(...)
.DollarNames(x, pattern)
```

## Default S3 method:
```r
.DollarNames(x, pattern = "")
```

## S3 method for class 'list'
```r
.DollarNames(x, pattern = "")
```

## S3 method for class 'environment'
```r
.DollarNames(x, pattern = "")
```
Arguments

- **ops**: Activates completion after the $ and @ operators.
- **ns**: Controls namespace related completions.
- **args**: Enables completion of function arguments.
- **func**: Enables detection of functions. If enabled, a customizable extension ("(" by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.
- **S3**: When args = TRUE, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).
- **ipck**: Enables completion of installed package names inside library and require.
- **data**: Enables completion of data sets (including those already visible) inside data.
- **help**: Enables completion of help requests starting with a question mark, by looking inside help index files.
- **argdb**: When args = TRUE, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to args. While this gives results that are technically correct, the use of the ... argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting argdb = TRUE enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function .addFunctionInfo (see below).
- **fuzzy**: Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change.
- **quotes**: Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by ?, help completion is invoked. Setting this to FALSE relegates completion to the underlying completion front-end, which may do its own processing (for example, readline on Unix-alikes will do filename completion).
- **files**: Deprecated. Use quotes instead.

All settings are turned on by default except ipck, func, and fuzzy. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

name, ... user-settable options. Currently valid names are

- **function.suffix**: default "(" 
- **funarg.suffix**: default " = " 
- **package.suffix** default "::" 

Usage is similar to that of options.
An R object for which valid names after "$" are computed and returned.

Pattern

A regular expression. Only matching names are returned.

Details

There are several types of completion, some of which can be disabled using \texttt{rc.settings}. The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., \texttt{TRUE}). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

Completion after extractors $ and @: When the \texttt{ops} setting is turned on, completion after $ and @ is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of [], $, etc \textit{do not inhibit evaluation}).

Valid completions after the $ extractor are determined by the generic function \texttt{DollarNames}. Some basic methods are provided, and more can be written for custom classes.

Completion inside namespaces: When the \texttt{ns} setting is turned on, completion inside namespaces is attempted when a token is preceded by the :: or :::: operators. Additionally, the basic completion mechanism is extended to include all loaded namespaces, i.e., \texttt{foopkg::} becomes a valid completion of \texttt{foo} if "\texttt{foopkg}" is a loaded namespace.

The completion of package namespaces applies only to already loaded namespaces, i.e. if \texttt{MASS} is not loaded, \texttt{MAS} will not complete to \texttt{MASS::}. However, attempted completion inside an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on \texttt{MASS::fr} will load \texttt{MASS} if it is not already loaded.

Completion for help items: When the \texttt{help} setting is turned on, completion on help topics is attempted when a token is preceded by ?. Prefixes (such as \texttt{class}, \texttt{method}) are supported, as well as quoted help topics containing special characters.

Completion of function arguments: When the \texttt{args} setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually +). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that \ldots is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of \textit{all} currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generic functions with many methods (like \texttt{print} and \texttt{plot}), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the \texttt{S3} setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are
often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete \texttt{seq(TAB)} and \texttt{seq(from = 1, TAB)} will both list only the arguments of \texttt{seq} (or any of its methods), whereas trying to complete \texttt{seq(length[TAB]} will list both the \texttt{length} argument and the \texttt{length} function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

**Special functions:** For a few special functions (\texttt{library}, \texttt{data}, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The \texttt{ipck} setting, which controls whether \texttt{library} and \texttt{require} will complete on \texttt{installed.packages}, is disabled by default because the first call to \texttt{installed.packages} is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to \texttt{installed.packages} is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

**Value**

If \texttt{rc.settings} is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns \texttt{NULL} invisibly.

\texttt{rc.status} returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to \texttt{rc.status} itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

- \texttt{comps}: The possible completions generated by the last call to \texttt{.completeToken}, as a character vector.
- \texttt{token}: The token that was (or, is to be) completed, as set by the last call to \texttt{.assignToken} (possibly inside a call to \texttt{.guessTokenFromLine}).
- \texttt{linebuffer}: The full line, as set by the last call to \texttt{.assignLinebuffer}.
- \texttt{start}: The start position of the token in the line buffer, as set by the last call to \texttt{.assignStart}.
- \texttt{end}: The end position of the token in the line buffer, as set by the last call to \texttt{.assignEnd}.
- \texttt{fileName}: Logical, indicating whether the cursor is currently inside quotes.
- \texttt{fguess}: The name of the function the cursor is currently inside.
- \texttt{isFirstArg}: Logical. If cursor is inside a function, is it the first argument?

In addition, the components \texttt{settings} and \texttt{options} give the current values of settings and options respectively.

\texttt{rc.getOption} and \texttt{rc.options} behave much like \texttt{getOption} and \texttt{options} respectively.

**Unexported API**

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:
The first four functions set up a completion attempt by specifying the token to be completed (\texttt{text}),
and indicating where (\texttt{start} and \texttt{end}, which should be integers) the token is placed within the
complete line typed so far (\texttt{line}).

Potential completions of the token are generated by \texttt{.completeToken}, and the completions can
be retrieved as an R character vector using \texttt{.retrieveCompletions}. It is possible for the user to
specify a replacement for this function by setting \texttt{rc.options("custom.completer")}; if not \texttt{NULL},
this function is called to compute potential completions. This facility is meant to help in situations
where completing as R code is not appropriate. See source code for more details.

If the cursor is inside quotes, completion may be suppressed. The function \texttt{.getFileComp} can be
used after a call to \texttt{.completeToken} to determine if this is the case (returns \texttt{TRUE}), and alterna-
tive completions generated as deemed useful. In most cases, filename completion is a reasonable
fallback.

The \texttt{.guessTokenFromLine} function is provided for use with backends that do not already break a
line into tokens. It requires the linebuffer and endpoint (cursor position) to be already set, and itself
sets the token and the start position. It returns the token as a character string.

The \texttt{.win32consoleCompletion} is similar in spirit, but is more geared towards the Windows GUI
(or rather, any front-end that has no completion facilities of its own). It requires the linebuffer and
cursor position as arguments, and returns a list with three components, \texttt{addition}, \texttt{possible}
and \texttt{comps}. If there is an unambiguous extension at the current position, \texttt{addition} contains the
additional text that should be inserted at the cursor. If there is more than one possibility, these are
available either as a character vector of preformatted strings in possible, or as a single string in
\texttt{comps}. possible consists of lines formatted using the current \texttt{width} option, so that printing them
on the console one line at a time will be a reasonable way to list them. \texttt{comps} is a space separated
(collapsed) list of the same completions, in case the front-end wishes to display it in some other
fashion.

The \texttt{minlength} argument can be used to suppress completion when the token is too short (which can
be useful if the front-end is set up to try completion on every keypress). If \texttt{check.repeat} is \texttt{TRUE},
it is detected if the same completion is being requested more than once in a row, and ambiguous
completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour,
where a single TAB completes up to any unambiguous part, and multiple possibilities are reported
only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.
The function \texttt{.addFunctionInfo} can be used to add information about the permitted argument
names for specific functions. Multiple named arguments are allowed in calls to it, where the tags
are names of functions and values are character vectors representing valid arguments. When the argdb setting is TRUE, these are used as a source of valid argument names for the relevant functions.

Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set ops = FALSE. Otherwise, trying to complete foo@ba will evaluate foo, trying to complete foo[i, 1:10]$ba will evaluate foo[i, 1:10], etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this will affect promises and lazy loaded symbols.

**read.DIF**

*Data Input from Spreadsheet*

**Description**

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

**Usage**

```r
read.DIF(file, header = FALSE, dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"), row.names, col.names, as.is = !stringsAsFactors, na.strings = "NA", colClasses = NA, nrows = -1, skip = 0, check.names = TRUE, blank.lines.skip = TRUE, stringsAsFactors = default.stringsAsFactors(), transpose = FALSE, fileEncoding = ")
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file</td>
<td>the name of the file which the data are to be read from, or a connection, or a complete URL. The name &quot;clipboard&quot; may also be used on Windows, in which case <code>read.DIF(&quot;clipboard&quot;)</code> will look for a DIF format entry in the Windows clipboard.</td>
</tr>
<tr>
<td>header</td>
<td>a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.</td>
</tr>
<tr>
<td>dec</td>
<td>the character used in the file for decimal points.</td>
</tr>
<tr>
<td>numerals</td>
<td>string indicating how to convert numbers whose conversion to double precision would lose accuracy, see <code>type.convert</code>.</td>
</tr>
</tbody>
</table>
row.names a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering.

col.names a vector of optional names for the variables. The default is to use "V" followed by the column number.

as.is the default behavior of read.DIF is to convert character variables to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logics (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors. Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using type.convert as in read.table. Note: to suppress all conversions including those of numeric columns, set colClasses = "character". Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

na.strings a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.

colClasses character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA. Possible values are NA (when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class. Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).

nrows the maximum number of rows to read in. Negative values are ignored.

skip the number of lines of the data file to skip before beginning to read data.

check.names logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates.

blank.lines.skip logical: if TRUE blank lines in the input are ignored.

stringsAsFactors logical: should character vectors be converted to factors?

transpose logical, indicating if the row and column interpretation should be transposed. Microsoft's Excel has been known to produce (non-standard conforming) DIF files which would need transpose = TRUE to be read correctly.

fileEncoding character string: if non-empty declares the encoding used on a file (not a connection or clipboard) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file, the ‘R Data Import/Export Manual’ and ‘Note’.
Value

A data frame (data.frame) containing a representation of the data in the file. Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame.

Note

The columns referred to in as.is and colClasses include the column of row names (if any).

Less memory will be used if colClasses is specified as one of the six atomic vector classes.

Author(s)

R Core; transpose option by Christoph Buser, ETH Zurich

References

The DIF format specification can be found by searching on http://www.wotsit.org/; the optional header fields are ignored. See also https://en.wikipedia.org/wiki/Data_Exchange_Format.

The term is likely to lead to confusion: Windows will have a ‘Windows Data Exchange Format (DIF) data format’ as part of its WinFX system, which may or may not be compatible.

See Also

The R Data Import/Export manual.

scan, type.convert, read.fwf for reading fixed width formatted input; read.table; data.frame.

Examples

### read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))

**Read Fixed-Format Data in a Fortran-like Style**

Read fixed-format data files using Fortran-style format specifications.

Usage

read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
read.fortran

Arguments

- **file**: File or connection to read from.
- **format**: Character vector or list of vectors. See ‘Details’ below.
- **...**: Other arguments for `read.fwf`.
- **as.is**: Keep characters as characters?
- **colClasses**: Variable classes to override defaults. See `read.table` for details.

Details

The format for a field is of one of the following forms: `rFl.d`, `rDl.d`, `rXl`, `rAl`, `rIl`, where `l` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `l` is required except for `X` formats when `r` is present.

For a single-line record, `format` should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (X) columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.

Value

A data frame

Note

`read.fortran` does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying `d > 0` in the `F` or `D` format will shift the decimal `d` places to the left, even if it is explicitly specified in the input file.

`read.fwf`, `read.table`, `read.csv`

Examples

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1","F2.0","I2"))
read.fortran(ff, c("2F1.0","2X","2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1","A2"), c("3I2","2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```
**read.fwf**  

**Description**  
Read a table of fixed width formatted data into a `data.frame`.

**Usage**
```r
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names, col.names, n = -1,
         buffersize = 2000, fileEncoding = ",", ...)
```

**Arguments**
- `file`  
  the name of the file which the data are to be read from. Alternatively, `file` can be a `connection`, which will be opened if necessary, and if so closed at the end of the function call.

- `widths`  
  integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.

- `header`  
  a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by `sep`.

- `sep`  
  character; the separator used internally; should be a character that does not occur in the file (except in the header).

- `skip`  
  number of initial lines to skip; see `read.table`.

- `row.names`  
  see `read.table`.

- `col.names`  
  see `read.table`.

- `n`  
  the maximum number of records (lines) to be read, defaulting to no limit.

- `buffersize`  
  Maximum number of lines to read at one time

- `fileEncoding`  
  character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for `file`, the ‘R Data Import/Export Manual’ and ‘Note’.

- `...`  
  further arguments to be passed to `read.table`. Useful such arguments include `as.is`, `na.strings`, `colClasses` and `strip.white`.

**Details**
Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in `file` are replaced by `NA`.

Negative-width fields are used to indicate columns to be skipped, e.g., -5 to skip 5 columns. These fields are not seen by `read.table` and so should not be included in a `col.names` or `colClasses` argument (nor in the header line, if present).

Reducing the `buffersize` argument may reduce memory use when reading large files with long lines. Increasing `buffersize` may result in faster processing when enough memory is available.

Note that `read.fwf` (not `read.table`) reads the supplied file, so the latter’s argument encoding will not be useful.
read.socket

**Value**

A `data.frame` as produced by `read.table` which is called internally.

**Author(s)**

Brian Ripley for R version: originally in Perl by Kurt Hornik.

**See Also**

`scan` and `read.table`.

`read.fortran` for another style of fixed-format files.

**Examples**

```r
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3))  #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3)) #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3))  #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
```

---

**Description**

`read.socket` reads a string from the specified socket, `write.socket` writes to the specified socket. There is very little error checking done by either.

**Usage**

```r
read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
```

**Arguments**

- `socket` a socket object.
- `maxlen` maximum length (in bytes) of string to read.
- `loop` wait for ever if there is nothing to read?
- `string` string to write to socket.

**Value**

`read.socket` returns the string read as a length-one character vector. `write.socket` returns the number of bytes written.

{
  if (!is.character(user))
    stop("user name must be a string")
  user <- paste(user, "\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
## Not run:
finger("root")  ## only works if your site provides a finger daemon
## End(Not run)

read.table

Data Input

Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

Usage

read.table(file, header = FALSE, sep = "", quote = "\n", dec = ",", numerals = c("allow.loss", "warn.loss", "no.loss"), row.names, col.names, as.is = !stringsAsFactors, na.strings = "NA", colClasses = NA, nrow = -1, skip = 0, check.names = TRUE, fill = !blank.lines.skip, strip.white = FALSE, blank.lines.skip = TRUE, comment.char = ",", allowEscapes = FALSE, flush = FALSE, stringsAsFactors = default.stringsAsFactors(), fileEncoding = ",", encoding = "unknown", text, skipNul = FALSE)

read.csv(file, header = TRUE, sep = ",", quote = "\n",...
Arguments

- **file**: the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an *absolute* path, the file name is *relative* to the current working directory, `getwd()`. Tilde-expansion is performed where supported. This can be a compressed file (see `file`). Alternatively, `file` can be a readable text-mode connection (which will be opened for reading if necessary, and if so closed (and hence destroyed) at the end of the function call). (If `stdin()` is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on `stdin()` will be cleared before return.) `file` can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for `url`.)

- **header**: a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: `header` is set to `TRUE` if and only if the first row contains one fewer field than the number of columns.

- **sep**: the field separator character. Values on each line of the file are separated by this character. If `sep = ""` (the default for `read.table`) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.

- **quote**: the set of quoting characters. To disable quoting altogether, use `quote = ""`. See `scan` for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless `colClasses` is specified.

- **dec**: the character used in the file for decimal points.

- **numerals**: string indicating how to convert numbers whose conversion to double precision would lose accuracy, see `type.convert`. Can be abbreviated. (Applies also to complex-number inputs.)

- **row.names**: a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if `row.names` is missing, the rows are numbered. Using `row.names = NULL` forces row numbering. Missing or `NULL` `row.names` generate row names that are considered to be ‘automatic’ (and not preserved by `as.matrix`).

- **col.names**: a vector of optional names for the variables. The default is to use "V" followed by the column number.
The default behavior of `read.table` is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable `as.is` controls the conversion of columns not otherwise specified by `colClasses`. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.

Note: to suppress all conversions including those of numeric columns, set `colClasses = "character"`. Note that `as.is` is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

`na.strings` a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. Note that the test happens after white space is stripped from the input, so `na.strings` values may need their own white space stripped in advance.

`colClasses` character. A vector of classes to be assumed for the columns. If unnamed, recycled as necessary. If named, names are matched with unspecified values being taken to be NA. Possible values are NA (the default, when `type.convert` is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package `methods`) for conversion from "character" to the specified formal class.

Note that `colClasses` is specified per column (not per variable) and so includes the column of row names (if any).

`nrows` integer: the maximum number of rows to read in. Negative and other invalid values are ignored.

`skip` integer: the number of lines of the data file to skip before beginning to read data.

`check.names` logical. If `TRUE` then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by `make.names`) so that they are, and also to ensure that there are no duplicates.

`fill` logical. If `TRUE` then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.

`strip.white` logical. Used only when `sep` has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See `scan` for further details (including the exact meaning of ‘white space’), remembering that the columns may include the row names.

`blank.lines.skip` logical: if `TRUE` blank lines in the input are ignored.

`comment.char` character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.

`allowEscapes` logical. Should C-style escapes such as \n be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see `scan`.

`flush` logical: if `TRUE`, `scan` will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.

`stringsAsFactors` logical: should character vectors be converted to factors? Note that this is overridden by `as.is` and `colClasses`, both of which allow finer control.
read.table

fileEncoding  character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for file, the ‘R Data Import/Export Manual’ and ‘Note’.

encoding  encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see Encoding): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See ‘Value’ and ‘Note’.

text  character string: if file is not supplied and this is, then data are read from the value of text via a text connection. Notice that a literal string can be used to include (small) data sets within R code.

skipNul  logical: should nuls be skipped?

...  Further arguments to be passed to read.table.

Details

This function is the principal means of reading tabular data into R.

Unless colClasses is specified, all columns are read as character columns and then converted using type.convert to logical, integer, numeric, complex or (depending on as.is) factor as appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If row.names is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If row.names is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole input if it has less than five lines), or from the length of col.names if it is specified and is longer. This could conceivably be wrong if fill or blank.lines.skip are true, so specify col.names if necessary (as in the ‘Examples’).

read.csv and read.csv2 are identical to read.table except for the defaults. They are intended for reading ‘comma separated value’ files (‘.csv’) or (read.csv2) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, read.delim and read.delim2 are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that header = TRUE and fill = TRUE in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided blank.lines.skip is TRUE; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded nuls are unsupported: skipping them (with skipNul = TRUE) may work.

Value

A data frame (data.frame) containing a representation of the data in the file.

Empty input is an error unless col.names is specified, when a 0-row data frame is returned: similarly giving just a header line if header = TRUE results in a 0-row data frame. Note that in either case the columns will be logical unless colClasses was supplied.

Character strings in the result (including factor levels) will have a declared encoding if encoding is "latin1" or "UTF-8".
Memory usage

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the 'R Data Import/Export' manual, supplementing the notes here.

Less memory will be used if colClasses is specified as one of the six atomic vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using nrows, even as a mild over-estimate, will help memory usage.

Using comment.char = "" will be appreciably faster than the read.table default.

read.table is not the right tool for reading large matrices, especially those with many columns: it is designed to read data frames which may have columns of very different classes. Use scan instead for matrices.

Note

The columns referred to in as.is and colClasses include the column of row names (if any). There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the encoding argument to declare that. If the input is in some other encoding, then it may be translated on input. The fileEncoding argument achieves this by setting up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

References

See Also

The 'R Data Import/Export' manual.

scan, type.convert, read.fwf for reading fixed width formatted input; write.table; data.frame.

count.fields can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the 'Examples' below).

https://tools.ietf.org/html/rfc4180 for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

Examples

## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
test1 <- c(!:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)
read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE, 
          col.names = paste0("V", seq_len(ncol)))
unlink(tf)
recover

```r
## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
1 2
3 4"
)
```

---

**Description**

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

**Usage**

```r
recover()
```

**Details**

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R `browser` is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

**Value**

Nothing useful is returned. However, you can invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

**Compatibility Note**

The R `recover` function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

**References**

See the compatibility note above, however.
See Also

browser for details about the interactive computations; options for setting the error option;
dump.frames to save the current environments for later debugging.

## End(Not run)
```

relist

Allow Re-Listing an unlist()ed Object

Description

relist() is an S3 generic function with a few methods in order to allow easy inversion of
unlist(obj) when that is used with an object obj of (S3) class "relistable".

Usage

```r
relist(flesh, skeleton)
## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'factor'
```
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

## S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)

Arguments

- **flesh**
  - a vector to be relisted
- **skeleton**
  - a list, the structure of which determines the structure of the result
- **x**
  - an R object, typically a list (or vector).
- **recursive**
  - logical. Should unlisting be applied to list components of x?
- **use.names**
  - logical. Should names be preserved?

Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including optim and nlm can only operate on functions whose domain is a vector. R has unlist() to convert nested list objects into a vector representation. relist(), its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as optim()) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```r
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))).
```

However, optim cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function mvdnorm(x, mean, vcov, log = FALSE) which computes the required probability density, then

```r
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar))
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
               log = TRUE))
}

optim(unlist(initial.param), ll)
```

relist takes two parameters: skeleton and flesh. Skeleton is a sample object that has the right shape but the wrong content. flesh is a vector with the right content but the wrong shape. Invoking
relist(flesh, skeleton)

will put the content of flesh on the skeleton. You don’t need to specify skeleton explicitly if the
skeleton is stored as an attribute inside flesh. In particular, if flesh was created from some object
obj with unlist(as.relistable(obj)) then the skeleton attribute is automatically set. (Note that
this does not apply to the example here, as optim is creating a new vector to pass to ll and not its
par argument.)

As long as skeleton has the right shape, it should be a precise inverse of unlist. These equalities
hold:

\[
\text{relist}(\text{unlist}(x), x) = x
\]
\[
\text{unlist}(\text{relist}(y, \text{skeleton})) = y
\]

\[
x <- \text{as.relistable}(x)
\]
\[
\text{relist}(\text{unlist}(x)) = x
\]

Value

an object of (S3) class "relistable" (and "list").

Author(s)

R Core, based on a code proposal by Andrew Clausen.

unlist

Examples

ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))

---

**REMOVE**

*Remove Add-on Packages*

**Description**

Utility for removing add-on packages.

**Usage**

R CMD REMOVE [options] [-l lib] pkgs

**Arguments**

pkgs a space-separated list with the names of the packages to be removed.

lib the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form ‘-library=lib’.

options further options for help or version.
remove.packages

Details

If used as R CMD REMOVE pkgs without explicitly specifying lib, packages are removed from the
library tree rooted at the first directory in the library path which would be used by R run in the
current environment.
To remove from the library tree lib instead of the default one, use R CMD REMOVE -l lib pkgs.
Use R CMD REMOVE --help for more usage information.

Note

Some binary distributions of R have REMOVE in a separate bundle, e.g. an R-devel RPM.

See Also

INSTALL, remove.packages

remove.packages

Remove Installed Packages

Description

Removes installed packages/bundles and updates index information as necessary.

Usage

remove.packages(pkgs, lib)

Arguments

pkgs a character vector with the names of the packages to be removed.
lib a character vector giving the library directories to remove the packages from. If
missing, defaults to the first element in .libPaths().

See Also

REMOVE for a command line version; install.packages for installing packages.

removeSource

Remove Stored Source from a Function

Description

When options("keep.source") is TRUE, a copy of the original source code to a function is stored
with it. This function removes that copy.

Usage

removeSource(fn)
Arguments

fn A single function from which to remove the source.

Details

This removes the "srcref" and related attributes.

Value

A copy of the function with the source removed.

See Also

srcref for a description of source reference records, deparse for a description of how functions are deparsed.

Examples

```r
fn <- function(x) {
  x + 1  # A comment, kept as part of the source
}
fn
fn <- removeSource(fn)
fn
```

RHOME R Home Directory

Description

Returns the location of the R home directory, which is the root of the installed R tree.

Usage

R RHOME

roman Roman Numerals

Description

Simple manipulation of (a small set of) integer numbers as roman numerals.

Usage

```r
as.roman(x)
.romans
```

Arguments

x a numeric or character vector of arabic or roman numerals.
as.roman creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, coercion, etc, see methods(class = "roman").

Only numbers between 1 and 3899 have a unique representation as roman numbers.

.romans is the basic dictionary, a named character vector.

References

Examples

## First five roman 'numbers'.
(y <- as.roman(1 : 5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## Today, and 10, 20, 30, and 100 years ago ...
y - 10*c(0:3,10)

## mixture of arabic and roman numbers :
as.roman(c(NA, 1:3, ",", strrep("I", 1:6))) # + NA with a warning for "IIIIII"
cc <- c(NA, 1:3, strrep("I", 0:5))
(rc <- as.roman(cc)) # two NAs: 0 is not "roman"
(ic <- as.integer(rc)) # works automatically [without an explicit method]
## simple consistency checks -- arithmetic when result is in \{1,2,...,3899\}:
stopifnot(identical(rc, as.roman(rc)), # as.roman(.) is "idempotent"
identical(rc + rc + (3*rc), rc*5),
identical(ic, c(NA, 1:3, NA, 1:5)),
identical(as.integer(5*rc), 5L*ic),
identical(as.numeric(rc), as.numeric(ic)),
identical(as.list(rc), as.list(ic)))

Rprof

Enable Profiling of R's Execution

Description

Enable or disable profiling of the execution of R expressions.

Usage

Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
memory.profiling = FALSE, gc.profiling = FALSE,
line.profiling = FALSE, numfiles = 100L, bufsize = 10000L)
**Arguments**

- **filename**: The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.
- **append**: logical: should the file be over-written or appended to?
- **interval**: real: time interval between samples.
- **memory.profiling**: logical: write memory use information to the file?
- **gc.profiling**: logical: record whether GC is running?
- **line.profiling**: logical: write line locations to the file?
- **numfiles, bufsize**: integers: line profiling memory allocation

**Details**

Enabling profiling automatically disables any existing profiling to another or the same file. Profiling works by writing out the call stack every `interval` seconds, to the file specified. Either the `summaryRprof` function or the wrapper script `R CMD Rprof` can be used to process the output file to produce a summary of the usage; use `R CMD Rprof --help` for usage information.

How time is measured varies by platform: on a Unix-alike it is the CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by `system` to return.

Note that the timing interval cannot usefully be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10msecs).

Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some primitive functions do not do so: specifically those which are of type "special" (see the ‘R Internals’ manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is TRUE, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.

**Note**

Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with ‘--disable-R-profiling’ to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof` in an executable built for C-level profiling.

**Note**

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numfiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.
Rprofmem

Enable Profiling of R’s Memory Use

Description

Enable or disable reporting of memory allocation in R.

Usage

Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)

Arguments

filename The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.
append logical: should the file be over-written or appended to?
threshold numeric: allocations on R’s “large vector” heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time malloc is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which malloc is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

summaryRprof to analyse the output file.

tracemem, Rprofmem for other ways to track memory use.

Examples

## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
...
## Now post-process the output as described in Details
## End(Not run)
Note

The memory profiler slows down R even when not in use, and so is a compile-time option. The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, Rprof also collects memory information.

tracemem traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"

Examples

## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)

---

**Rscript**

*Scripting Front-End for R*

**Description**

This is an alternative front end for use in `#!` scripts and other scripting applications.

**Usage**

Rscript [options] [-e expr [-e expr2 ...] | file] [args]

**Arguments**

options  a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details.
expr, expr2  R expression(s), properly quoted.
file  the name of a file containing R commands. ‘-’ indicates ‘stdin’.
args  arguments to be passed to the script in file.
Details

`Rscript --help` gives details of usage, and `Rscript --version` gives the version of `Rscript`.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing ‘`#!`’ scripts since it is an executable and takes `file` directly as an argument. Options ‘`--slave --no-restore`’ are always supplied: these imply ‘`--no-save`’. Arguments that contain spaces cannot be specified directly on the ‘`#!`’ line, because spaces and tabs are interpreted as delimiters and there is no way to protect them from this interpretation on the ‘`#!`’ line. (The standard Windows command line has no concept of ‘`#!`’ scripts, but Cygwin shells do.)

Either one or more ‘`-e`’ options or `file` should be supplied. When using ‘`-e`’ options be aware of the quoting rules in the shell used: see the examples.

Additional options accepted (before `file` or `args`) are

‘`--verbose`’ gives details of what `Rscript` is doing. Also passed on to `R`.

‘`--default-packages=list`’ where `list` is a comma-separated list of package names or `NULL`. Sets the environment variable `R_DEFAULT_PACKAGES` which determines the packages loaded on startup.

Spaces are allowed in `expression` and `file` (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

If ‘`--default-packages`’ is not used, then `Rscript` checks the environment variable `R_SCRIPT_DEFAULT_PACKAGES`. If this is set, then it takes precedence over `R_DEFAULT_PACKAGES`.

Normally the version of `R` is determined at installation, but this can be overridden by setting the environment variable `RHOME`.

`stdin()` refers to the input file, and `file("stdin")` to the stdin file stream of the process.

Note

`Rscript` is only supported on systems with the `execv` system call.

Examples

```r
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

# Get the same initial packages in the same order as default `R`:
Rscript --default-packages=methods,datasets,utils,grDevices,graphics,stats -e 'sessionInfo()'
```

```r
## example `#!` script for a Unix-alike

#!/path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```
RShowDoc

Show R Manuals and Other Documentation

Description

Utility function to find and display R documentation.

Usage

RShowDoc(what, type = c("pdf", "html", "txt"), package)

Arguments

what a character string: see ‘Details’.

type an optional character string giving the preferred format. Can be abbreviated.

package an optional character string specifying the name of a package within which to look for documentation.

Details

what can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in ‘share/licenses’, FAQ (also available as R-FAQ), and the files in ‘R_HOME/doc’.

Only on Windows, the R for Windows FAQ is specified by rw-FAQ.

If package is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If what is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in type (or "pdf" if none is specified).

Value

A invisible character string given the path to the file found.

See Also

For displaying regular help files, help (or ?) and help.start.

For type = "txt", file.show is used. vignettes are nicely viewed via RShowDoc(*, package= . ).

Examples

RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")
RSiteSearch

Search for Key Words or Phrases in Documentation

Description

Search for key words or phrases in help pages, vignettes or task views, using the search engine at http://search.r-project.org and view them in a web browser.

Usage

RSiteSearch(string,
    restrict = c("functions", "vignettes", "views"),
    format = c("normal", "short"),
    sortby = c("score", "date:late", "date:early",
                "subject", "subject:descending",
                "from", "from:descending",
                "size", "size:descending"),
    matchesPerPage = 20)

Arguments

string A character string specifying word(s) or a phrase to search. If the words are to be searched as one entity, enclose all words in braces (see the first example).

restrict a character vector, typically of length greater than one. Values can be abbreviated. Possible areas to search in: functions for help pages, views for task views and vignettes for package vignettes.

format normal or short (no excerpts); can be abbreviated.

sortby character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for subject in alphabetical order, subject:descending for reverse alphabetical order, from or from:descending for sender (when applicable), size or size:descending for size.)

matchesPerPage How many items to show per page.

Details

This function is designed to work with the search site at http://search.r-project.org, and depends on that site continuing to be made available (thanks to Jonathan Baron and the School of Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron
rtags provides etags-like indexing capabilities for R code, using R’s own parser.

Arguments passed on to `list.files` to determine the files to be tagged. By default, these are all files with extension .R, .r, .S, and .s in the current directory. These arguments are ignored if `src` is specified.

Arguments

**Path**, **Pattern**, **Recursive**
Arguments passed on to `list.files` to determine the files to be tagged. By default, these are all files with extension .R, .r, .S, and .s in the current directory. These arguments are ignored if `src` is specified.

**Src**
A vector of file names to be indexed.

**Keep.Re**
A regular expression further restricting `src` (the files to be indexed). For example, specifying `keep.re = '/R/[.^[]*\.
R$'` will only retain files with extension .R inside a directory named R.

**Ofile**
Passed on to `cat` as the file argument; typically the output file where the tags will be written (“TAGS” by convention). By default, the output is written to the R console (unless redirected).

**Append**
Logical, indicating whether the output should overwrite an existing file, or append to it.

**Verbose**
Logical. If TRUE, file names are echoed to the R console as they are processed.

---

**See Also**

`help.search`, `help.start` for local searches.
`browseURL` for how the help file is displayed.

**Examples**

```r
# need Internet connection
RSiteSearch("(logistic regression)")  # matches exact phrase
Sys.sleep(5)  # allow browser to open, take a quick look
## Search in vignettes and store the query-string:
fullquery <- RSiteSearch("lattice", restrict = "vignettes")
fullquery  # a string of ~ 110 characters
```
Details

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style ctags format and the and emacs-style etags format. Tag files in these formats are usually generated by the ctags and etags utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The rtags function is intended to be a tagging utility for R code. It parses R code files (using R’s parser) and produces tags in Emacs’ etags format. Support for vi-style tags is currently absent, but should not be difficult to add.

list.files, cat

Examples

## Not run:
rtags("/path/to/src/repo",
    pattern = "[.]*\.[RrSs]$",
    keep.re = "/R/",
    verbose = TRUE,
    ofile = "TAGS",
    append = FALSE,
    recursive = TRUE)

## End(Not run)
Arguments

- **file**: name of Sweave source file. See the description of the corresponding argument of Sweave.
- **syntax**: an object of class SweaveSyntax.
- **output**: name of output file used unless split = TRUE: see ‘Details’.
- **annotate**: a logical or function. When true, as by default, code chunks are separated by comment lines specifying the names and line numbers of the code chunks. If FALSE the decorating comments are omitted. Alternatively, annotate may be a function, see section ‘Chunk annotation’.
- **split**: split output into a file for each code chunk?
- **quiet**: logical to suppress all progress messages.
- **drop.eval FALSE**: logical; When false, as by default, all chunks with option eval = FALSE are commented out in the output; otherwise (drop.eval FALSE = TRUE) they are omitted entirely.
- **...**: additional named arguments setting defaults for further options listed in ‘Supported Options’.

Details

Unless split = TRUE, the default name of the output file is basename(file) with an extension corresponding to the Sweave syntax (e.g., ‘Rnw’, ‘Stex’) replaced by ‘R’. File names “stdout” and “stderr” are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the ‘engine’ (default ‘.R’).

Note that this driver does more than simply extract the code chunks verbatim, because chunks may re-use earlier chunks.

Chunk annotation (annotate)

By default annotate = TRUE, the annotation is of one of the forms

```
########################################################################
### code chunk number 3: viewport
########################################################################

########################################################################
### code chunk number 18: grid.Rnw:647-648
########################################################################

########################################################################
### code chunk number 19: trellisdata (eval = FALSE)
########################################################################
```

using either the chunk label (if present, i.e., when specified in the source) or the file name and line numbers.

annotate may be a function with formal arguments (options, chunk, output), e.g. to produce less dominant chunk annotations; see Rtangle()$runcode how it is called instead of the default.
**Supported Options**

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

- **engine**: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
- **keep.source**: logical (TRUE). If keep.source == TRUE the original source is copied to the file. Otherwise, deparsed source is output.
- **eval**: logical (TRUE). If FALSE, the code chunk is copied across but commented out.
- **prefix** Used if split = TRUE. See prefix.string.
- **prefix.string**: a character string, default is the name of the source file (without extension). Used if split = TRUE as the prefix for the filename if the chunk has no label, or if it has a label and prefix = TRUE. Note that this is used as part of filenames, so needs to be portable.
- **show.line.nos** logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

**Author(s)**

Friedrich Leisch and R-core.

'Sweave User Manual', a vignette in the **utils** package.

*Sweave, RweaveLatex*

**Examples**

```r
nmRnw <- "example-1.Rnw"
exfile <- system.file("Sweave", nmRnw, package = "utils")
## Create R source file
Stangle(exfile)
nmR <- sub("Rnw$", "R", nmRnw) # the (default) R output file name
if(interactive()) file.show("example-1.R")

## Smaller R source file with custom annotation:
my.Ann <- function(options, chunk, output) {
  cat("### chunk #", options$chunknr, ", options$chunknr, " ",
       if(!is.null(ol <- options$label)) ol else .RtangleCodeLabel(chunk),
       if(!options$eval) " (eval = FALSE)",
       file = output, sep = "")
}
Stangle(exfile, annotate = my.Ann)
if(interactive()) file.show("example-1.R")

Stangle(exfile, annotate = my.Ann, drop.evalFALSE=TRUE)
if(interactive()) file.show("example-1.R")
```
Description

A driver for Sweave that translates R code chunks in LaTeX files by “running them”, i.e., `parse()` and `eval()` each.

Usage

```r
RweaveLatex()
RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
    debug = FALSE, stylepath, ...)
```

Arguments

- **file**: Name of Sweave source file. See the description of the corresponding argument of Sweave.
- **syntax**: An object of class SweaveSyntax.
- **output**: Name of output file. The default is to remove extension `.nw`, `.Rnw` or `.Snw` and to add extension `.tex`. Any directory paths in file are also removed such that the output is created in the current working directory.
- **quiet**: If TRUE all progress messages are suppressed.
- **debug**: If TRUE, input and output of all code chunks is copied to the console.
- **stylepath**: See ‘Details’.
- **...**: named values for the options listed in ‘Supported Options’.

Details

The LaTeX file generated needs to contain the line `\usepackage{Sweave}`, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the RweaveLatex driver. If `stylepath = TRUE`, a hard-coded path to the file ‘Sweave.sty’ in the R installation is set in place of Sweave. The hard-coded path makes the LaTeX file less portable, but avoids the problem of installing the current version of ‘Sweave.sty’ to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for `stylepath` is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is FALSE if it is unset or empty. If set, it should be exactly TRUE or FALSE: any other values are taken as FALSE.

The simplest way for frequent Sweave users to ensure that ‘Sweave.sty’ is in the TeX input path is to add ‘`R_HOME/share/texmf`’ as a ‘`texmf tree`’ (‘root directory’ in the parlance of the ‘MiKTeX settings’ utility).

By default, ‘Sweave.sty’ sets the width of all included graphics to:

`\setkeys{Gin}{width=0.8\textwidth}`.

This setting affects the width size option passed to the ‘`\includegraphics{}`’ directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document.
Thus, for example, you may set \texttt{width=3} in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to \texttt{0.8\textwidth} and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the \texttt{`\setkeys{Gin}{width=...}`} directive in your \texttt{`.Rnw`} file after the \texttt{`\begin{document}`} directive and changing the \texttt{width} option value as you prefer, using standard \LaTeX{} measurement values.

If you wish to override this default behavior entirely, you can add a \texttt{`\usepackage[nogin]{Sweave}`} directive in your preamble. In this case, no size-scaling options will be passed to the \texttt{`\includegraphics{}`} directive and the height and width options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

\texttt{`Sweave.sty`} also supports the \texttt{`[noae]`} option, which suppresses the use of the \texttt{`ae`} package, the use of which may interfere with certain encoding and typeface selections. If you have problems in the rendering of certain character sets, try this option.

It also supports the \texttt{`[inconsolata]`} option, to render monospaced text in \texttt{inconsolata}, the font used by default for \texttt{R} help pages.

The use of fancy quotes (see \texttt{sQuote}) can cause problems when setting \texttt{R} output. Either set \texttt{options(useFancyQuotes = \texttt{FALSE})} or arrange that \LaTeX{} is aware of the encoding used (by a \texttt{`\usepackage[utf8]{inputenc}`} declaration: Windows users of \texttt{Sweave} from \texttt{Rgui.exe} will need to replace \texttt{`utf8`} by \texttt{`cp1252`} or similar) and ensure that typewriter fonts containing directional quotes are used.

Some \LaTeX{} graphics drivers do not include \texttt{`.png`} or \texttt{`.jpg`} in the list of known extensions. To enable them, add something like \texttt{`\DeclareGraphicsExtensions{.png,.pdf,.jpg}`} to the preamble of your document or check the behavior of your graphics driver. When both \texttt{pdf} and \texttt{png} are \texttt{TRUE} both files will be produced by \texttt{Sweave}, and their order in the \texttt{`\DeclareGraphicsExtensions`} list determines which will be used by \texttt{pdflatex}.

**Supported Options**

\texttt{RweaveLatex} supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from \texttt{Sweave} through \ldots but not when use in the header of a code chunk.

- **engine**: character string ("R"). Only chunks with engine equal to "R" or "S" are processed.
- **echo**: logical (\texttt{TRUE}). Include \texttt{R} code in the output file?
- **keep.source**: logical (\texttt{TRUE}). When echoing, if \texttt{keep.source} == \texttt{TRUE} the original source is copied to the file. Otherwise, deparsed source is echoed.
- **eval**: logical (\texttt{TRUE}). If \texttt{FALSE}, the code chunk is not evaluated, and hence no text nor graphical output produced.
- **results**: character string ("verbatim"). If "verbatim", the output of \texttt{R} commands is included in the verbatim-like `\texttt{Soutput}` environment. If "tex", the output is taken to be already proper \LaTeX{} markup and included as is. If "hide" then all output is completely suppressed (but the code executed during the weave). Values can be abbreviated.
- **print**: logical (\texttt{FALSE}). If \texttt{TRUE}, this forces auto-printing of all expressions.
- **term**: logical (\texttt{TRUE}). If \texttt{TRUE}, visibility of values emulates an interactive \texttt{R} session: values of assignments are not printed, values of single objects are printed. If \texttt{FALSE}, output comes only from explicit \texttt{print} or similar statements.
- **split**: logical (\texttt{FALSE}). If \texttt{TRUE}, text output is written to separate files for each code chunk.
strip.white: character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.
A ‘blank line’ is one that is empty or includes only whitespace (spaces and tabs).
Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.

prefix: logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the prefix.string option: otherwise only unlabelled chunks use the prefix.

prefix.string: a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.

include: logical (TRUE), indicating whether input statements for text output (if split = TRUE) and ‘\includegraphics’ statements for figures should be auto-generated. Use include = FALSE if the output should appear in a different place than the code chunk (by placing the input line manually).

fig: logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

eps: logical (FALSE), indicating whether EPS figures should be generated. Ignored if fig = FALSE.

df: logical (TRUE), indicating whether PDF figures should be generated. Ignored if fig = FALSE.

pdf.version, pdf.encoding, pdf.compress: passed to pdf to set the version, encoding and compression (or not). Defaults taken from pdf.options().

png: logical (FALSE), indicating whether PNG figures should be generated. Ignored if fig = FALSE. Only available in R >= 2.13.0.

jpeg: logical (FALSE), indicating whether JPEG figures should be generated. Ignored if fig = FALSE. Only available in R >= 2.13.0.

grdevice: character (NULL): see section ‘Custom Graphics Devices’. Ignored if fig = FALSE. Only available in R >= 2.13.0.

width: numeric (6), width of figures in inches. See ‘Details’.

height: numeric (6), height of figures in inches. See ‘Details’.

resolution: numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

concordance: logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

gfigs.only: logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a ‘\SweaveOpts{}’ line in the document. For unknown options, their type is set at first use.

Custom Graphics Devices

If option grdevice is supplied for a code chunk with both fig and eval true, the following call is made
get(options$grdevice, envir = .GlobalEnv)(name=, width=,
    height=, options)

which should open a graphics device. The chunk’s code is then evaluated and \texttt{dev.off} is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

\begin{verbatim}
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
grDevices::png(filename = paste(name, "png", sep = "."),
    width = width, height = height, res = 100,
    units = "in", type = "quartz", bg = "transparent")
@
\end{verbatim}

Alternatively for $R \geq 3.4.0$, if the function exists in a package (rather than the \texttt{.GlobalEnv}) it can be used by setting \texttt{grdevice = "pkg::my.Swd"} (or with \texttt{":::"} instead of \texttt{::} if the function is not exported).

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for \texttt{dev.off} can be provided as a function with suffix \texttt{.off}, e.g. \texttt{my.Swd.off()} or \texttt{pkg::my.Swd.off()}, respectively.

\section*{Hook Functions}

Before each code chunk is evaluated, zero or more hook functions can be executed. If \texttt{getOption("SweaveHooks")} is set, it is taken to be a named list of hook functions. For each \texttt{logical} option of a code chunk (\texttt{echo}, \texttt{print}, \ldots) a hook can be specified, which is executed if and only if the respective option is \texttt{TRUE}. Hooks must be named elements of the list returned by \texttt{getOption("SweaveHooks")} and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as \texttt{list(fig = foo)}, and \texttt{foo} is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called \texttt{clean} that removes all objects in the workspace. Then all code chunks specified with \texttt{clean = TRUE} would start operating on an empty workspace.

\texttt{Sweave, Rtangle}
savehistory

Load or Save or Display the Commands History

Description

Load or save or display the commands history.

Usage

loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
        prefix = "##------ ", suffix = " ------##",
        quiet = FALSE)

Arguments

file The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory.

max.show The maximum number of lines to show. Inf will give all of the currently available history.

reverse logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.

pattern A character string to be matched against the lines of the history. When supplied, only unique matching lines are shown.

... Arguments to be passed to grep when doing the matching.

stamp A value or vector of values to be written into the history.

prefix A prefix to apply to each line.

suffix A suffix to apply to each line.

quiet If TRUE, suppress printing timestamp to the console.

Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. There are separate versions of this help file for Unix and Windows.

The functions described here work on Unix-alikes under the readline command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that R can be built without readline.

R.app, the console on macOS, has a separate and largely incompatible history mechanism, which by default uses a file ‘.Rapp.history’ and saves up to 250 entries. These functions are not currently implemented there.

The readline history mechanism is controlled by two environment variables: R_HISTSIZE controls the number of lines that are saved (default 512), and R_HISTFILE (default ‘.Rhistory’) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for loadhistory/savehistory). There is no limit on the number of lines of history.
retained during a session, so setting `R_HISTSIZE` to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of `Sys.setenv`.

Note that `readline` history library saves files with permission `0600`, that is with read/write permission for the user and not even read permission for any other account.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism only the console message is printed.

**Note**

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to `savehistory()` in `.Last`. See the examples.

**Examples**

```r
## Not run:
## Save the history in the home directory: note that it is not
## (by default) read from there but from the current directory
.Last <- function()
  if(interactive()) try(savehistory("~/.Rhistory"))

## End(Not run)
```

---

select.list  
*Select Items from a List*

**Description**

Select item(s) from a character vector.

**Usage**

```r
select.list(choices, preselect = NULL, multiple = FALSE,
            title = NULL, graphics = getOption("menu.graphics"))
```

**Arguments**

- `choices`  
a character vector of items.
- `preselect`  
a character vector, or `NULL`. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
- `multiple`  
logical: can more than one item be selected?
- `title`  
optional character string for window title, or `NULL` for no title.
- `graphics`  
logical: should a graphical widget be used?
Details

The normal default is graphics = TRUE. Under the macOS GUI this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. On other Unix-like platforms it will use a Tcl/Tk listbox widget if possible.

If graphics is FALSE or no graphical widget is available it displays a text list from which the user can choose by number(s). The multiple = FALSE case uses menu. Preselection is only supported for multiple = TRUE, where it is indicated by a "+" preceding the item.

It is an error to use select.list in a non-interactive session.

Value

A character vector of selected items. If multiple is false and no item was selected (or Cancel was used), "" is returned. If multiple is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

menu, tk_select.list for a graphical version using Tcl/Tk.

Examples

## Not run:
select.list(sort(.packages(all.available = TRUE)))
## End(Not run)

sessionInfo

Collect Information About the Current R Session

Description

Print version information about R, the OS and attached or loaded packages.

Usage

sessionInfo(package = NULL)
## S3 method for class 'sessionInfo'
print(x, locale = TRUE, ...)
## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE, ...)

Arguments

package a character vector naming installed packages, or NULL (the default) meaning all attached packages.

x an object of class "sessionInfo".

object an object of class "sessionInfo".

locale show locale information?

... currently not used.
setRepositories

Value

An object of class "sessionInfo" which has print and toLatex methods. This is a list with components

R.version a list, the result of calling R.Version().
platform a character string describing the platform R was built under. Where sub-architectures are in use this is of the form 'platform/sub-arch (nn-bit)'.
running a character string describing the OS and version which it is running under (as distinct from built under). This attempts to name a Linux distribution and give the OS name on an Apple Mac.
matprod a character string, the result of calling options("matprod").
BLAS a character string, the result of calling extSoftVersion()["BLAS"].
LAPACK a character string, the result of calling La_library().
locale a character string, the result of calling Sys.getenvlocale().
basePkgs a character vector of base packages which are attached.
otherPkgs (not always present): a character vector of other attached packages.
loadedOnly (not always present): a named list of the results of calling packageDescription on packages whose namespaces are loaded but are not attached.

Note

The information on 'loaded' packages and namespaces is the current version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

How OSes identify themselves and their versions can be arcane: where possible running uses a human-readable form.

See Also

R.version

Examples

sessionInfo()
toLatex(sessionInfo(), locale = FALSE)

setRepositories Select Package Repositories

Description

Interact with the user to choose the package repositories to be used.

Usage

setRepositories(graphics =getOption("menu.graphics"),
       ind = NULL, addURLs = character())
setRepositories

Arguments

- **graphics** Logical. If true, use a graphical list: on Windows or macOS GUI use a list box, and on a Unix-alike if `tcltk` and an X server are available, use Tk widget. Otherwise use a text menu.

- **ind** NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for `graphics = FALSE`.

- **addURLs** A character vector of additional URLs: it is often helpful to use a named vector.

Details

The default list of known repositories is stored in the file `R_HOME/etc/repositories`. That file can be edited for a site, or a user can have a personal copy in the file pointed to by the environment variable `R_REPOSITORIES`, or if this is unset or does not exist, in `HOME/.R/repositories`, which will take precedence.

A Bioconductor mirror can be selected by setting `options("BioC_mirror")`, e.g. via `chooseBioCmirror` — the default value is `"https://bioconductor.org"`.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option "pkgType" as some repositories only offer a subset of types (e.g., only source packages or not macOS binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of `R`. (Type "both" is equivalent to "source".)

Repository `CRAN` is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element "CRAN": this ensures mirror selection is sticky.

This function requires the `R` session to be interactive unless `ind` is supplied.

Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous `repos` options setting (as a `list` with component `repos`) or `NULL` if no changes were applied.

Note

This does not set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic Startup).

See Also

- `chooseCRANmirror`, `chooseBioCmirror`, `install.packages`.

Examples

```r
## Not run:
setRepositories(addURLs =
c(CRANxtras = "http://www.stats.ox.ac.uk/pub/RWin"))
## End(Not run)
```
SHLIB

Build Shared Object/DLL for Dynamic Loading

Description

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using `dyn.load` or `library.dynam`.

Usage

```r
R CMD SHLIB [options] [-o dllname] files
```

Arguments

- `files`: a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automagically made from their sources) and library linking commands.
- `dllname`: the full name of the shared object/DLL to be built, including the extension (typically ‘.so’ on Unix systems, and ‘.dll’ on Windows). If not given, the basename of the object/DLL is taken from the basename of the first file.
- `options`: Further options to control the processing. Use `R CMD SHLIB --help` for a current list.

Details

`R CMD SHLIB` is the mechanism used by `INSTALL` to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add `cpp` flags and to add libraries to the link step) and for details of some of its quirks.

Items in `files` with extensions ‘.c’, ‘.cpp’, ‘.cc’, ‘.C’, ‘.f’, ‘.f90’, ‘.f95’, ‘.m’ (ObjC), ‘.M’ and ‘.mm’ (ObjC++) are regarded as source files, and those with extension ‘.o’ as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on macOS.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option ‘-n’ (also known as ‘--dry-run’) will show the commands that would be run without actually executing them.

Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

See Also

- `COMPILE`, `dyn.load`, `library.dynam`.
- The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on “Customizing compilation” in the former.
Examples

```r
## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml

## End(Not run)
```

sourceutils  Source Reference Utilities

Description

These functions extract information from source references.

Usage

```r
getSrcFilename(x, full.names = FALSE, unique = TRUE)
getSrcDirectory(x, unique = TRUE)
getSrcref(x)
getSrcLocation(x, which = c("line", "column", "byte", "parse"),
              first = TRUE)
```

Arguments

- `x`: An object (typically a function) containing source references.
- `full.names`: Whether to include the full path in the filename result.
- `unique`: Whether to list only unique filenames/directories.
- `which`: Which part of a source reference to extract. Can be abbreviated.
- `first`: Whether to show the first (or last) location of the object.

Details

Each statement of a function will have its own source reference if the "keep.source" option is `TRUE`. These functions retrieve all of them.

The components are as follows:

- `line`: The line number where the object starts or ends.
- `column`: The column number where the object starts or ends.
- `byte`: As for "column", but counting bytes, which may differ in case of multibyte characters.
- `parse`: As for "line", but this ignores `#line` directives.

Value

- `getSrcFilename` and `getSrcDirectory` return character vectors holding the filename/directory.
- `getSrcref` returns a list of "srcref" objects or `NULL` if there are none.
- `getSrcLocation` returns an integer vector of the requested type of locations.

See Also

`srcref`, `getParseData`
Examples

```r
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved

getSrcDirectory(fn)
getSrcLocation(fn, "line")
```

---

### stack

**Stack or Unstack Vectors from a Data Frame or List**

**Description**

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

**Usage**

```r
stack(x, ...)  
## Default S3 method:  
stack(x, drop=FALSE, ...)  
## S3 method for class 'data.frame'  
stack(x, select, drop=FALSE, ...)
```

```r
unstack(x, ...)  
## Default S3 method:  
unstack(x, form, ...)  
## S3 method for class 'data.frame'  
unstack(x, form, ...)
```

**Arguments**

- `x`: a list or data frame to be stacked or unstacked.
- `select`: an expression, indicating which variable(s) to select from a data frame.
- `form`: a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to `formula(x)` in the data frame method for `unstack`.
- `drop`: Whether to drop the unused levels from the “ind” column of the return value.
- `...`: further arguments passed to or from other methods.

**Details**

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to vectors (as determined by `is.vector`): non-vector columns (e.g., factors) will be ignored with a warning. Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.
These functions are generic: the supplied methods handle data frames and objects coercible to lists by \texttt{as.list}.

**Value**

unstack produces a list of columns according to the formula \texttt{form}. If all the columns have the same length, the resulting list is coerced to a data frame.

stack produces a data frame with two columns:

- values the result of concatenating the selected vectors in \texttt{x}.
- ind a factor indicating from which vector in \texttt{x} the observation originated.

**Author(s)**

Douglas Bates

**See Also**

\texttt{lm, reshape}

**Examples**

```r
require(stats)
formula(PlantGrowth) # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg) # now put it back together
stack(pg, select = -ctrl) # omitting one vector
```

---

**\texttt{str}** Compactley Display the Structure of an Arbitrary R Object

**Description**

Compactely display the internal structure of an R object, a diagnostic function and an alternative to \texttt{summary} (and to some extent, \texttt{dput}). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for any R object. It calls \texttt{args} for (non-primitive) function objects.

\texttt{strOptions()} is a convenience function for setting \texttt{options(str = .)}, see the examples.

**Usage**

```r
str(object, ...)
```

```
## S3 method for class 'data.frame'
str(object, ...)
```

```
## Default S3 method:
str(object, max.level = NA,
vec.len = strO$vec.len, digits.d = strO$digits.d,
nchar.max = 128, give.attr = TRUE,
```
str

drop.deparse.attr = str$drop.deparse.attr,
give.head = TRUE, give.length = give.head,
width =getOption("width"), nest.lev = 0,
indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
collapse = ".."),
comp.str = "$ ", no.list = FALSE, envir = baseenv(),
strict.width = str$strict.width,
formatNum = str$formatNum, list.len = 99, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
drop.deparse.attr = TRUE,
formatNum = function(x, ...)
  format(x, trim = TRUE, drop0trailing = TRUE, ...))

Arguments

object any R object about which you want to have some information.
max.level maximal level of nesting which is applied for displaying nested structures, e.g.,
a list containing sub lists. Default NA: Display all nesting levels.
vec.len numeric (>= 0) indicating how many ‘first few’ elements are displayed of each
vector. The number is multiplied by different factors (from .5 to 3) depending
on the kind of vector. Defaults to the vec.len component of option "str" (see
options) which defaults to 4.
digits.d number of digits for numerical components (as for print). Defaults to the
digits.d component of option "str" which defaults to 3.
nchar.max maximal number of characters to show for character strings. Longer strings
are truncated, see longch example below.
give.attr logical; if TRUE (default), show attributes as sub structures.
drop.deparse.attr logical; if TRUE (default). deparse(control = <S>) will not have
"showAttributes" in <S>. Used to be hard coded to FALSE and hence can be
be set via strOptions() for back compatibility.
give.length logical; if TRUE (default), indicate length (as [1:....]).
give.head logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as
<type>[1:....]).
width the page width to be used. The default is the currently active
options("width"); note that this has only a weak effect, unless strict.width
is not "no".
nest.lev current nesting level in the recursive calls to str.
indent.str the indentation string to use.
comp.str string to be used for separating list components.
no.list logical; if true, no ‘list of...’ nor the class are printed.
envir the environment to be used for promise (see delayedAssign) objects only.
strict.width string indicating if the width argument’s specification should be followed
strictly, one of the values c("no", "cut", "wrap"), which can be abbre-
viated. Defaults to the strict.width component of option "str" (see
options) which defaults to "no" for back compatibility reasons; "wrap" uses
strwrap(*, width = width) whereas "cut" cuts directly to width. Note that
a small vec.length may be better than setting strict.width = "wrap".
formatNum is a function such as `format` for formatting numeric vectors. It defaults to the formatNum component of option "str", see "Usage" of `strOptions()` above, which is almost back compatible to R <= 2.7.x, however, using `formatC` may be slightly better.

list.len numeric; maximum number of list elements to display within a level.

... potential further arguments (required for Method/Generic reasons).

Value

`str` does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

See Also

`ls.str` for listing objects with their structure; `summary`, `args`.

Examples

```r
require(stats); require(grDevices); require(graphics)
## The following examples show some of 'str' capabilities
str(1:12)
str(ls)
str(args) # more useful than  args(args) !
str(freey)
str(str)
str(.Machine, digits.d = 20) # extra digits for identification of binary numbers
str( lsfit(1:9, 1:9))
str( lsfit(1:9, 1:9), max.level = 1)
str( lsfit(1:9, 1:9), width = 60, strict.width = "cut")
str( lsfit(1:9, 1:9), width = 60, strict.width = "wrap")
opts <- options(); str(opts) # save first;
# otherwise internal options() is used.

## Long strings, 'nchar.max'; 'strict.width':
nchar(longch <- paste(rep(letters,100), collapse = ""))
str(longch)
str(longch, nchar.max = 52)
str(longch, strict.width = "wrap")

## Multibyte characters in strings (in multibyte locales):
```
strcapture <- Sys.getlocale("LC_CTYPE")
mbyte.lc <- if (.Platform$OS.type == "windows")  
"English.United States.28605" else "en_GB.UTF-8"
try(Sys.setlocale("LC_CTYPE", mbyte.lc))
## Truncation behavior (<> correct width measurement) for "long" non-ASCII:
idx <- c(65313:65338, 65345:65350)
fwch <- intToUtf8(idx) # full width character string: each has width 2
ch <- strtrim(paste(LETTERS, collapse="._"), 64)
(c.ch = nchar(ch), w.ch = nchar(ch, "w"),  
c.fw = nchar(fwch), w.fw = nchar(fwch, "w")))
stopifnot(unname(ncc) == c(64,64, 32, 64))
## nchar.max: 1st line needs an increase of 2 in order to see 1 (in UTF-8!):
invisible(lapply(60:66, function(N) str(fwch, nchar.max = N)))
invisible(lapply(60:66, function(N) str( ch , nchar.max = N))) # "1 is 1" here
## revert locale to previous:
Sys.setlocale("LC_CTYPE", oloc)

## Settings for narrow transcript :
op <- options(width = 60,  
str = strOptions(strict.width = "wrap"))
str(lsfit(1:9,1:9))
str(options())
## reset to previous:
options(op)

str(quote( { A+B; list(C, D) } ))

## S4 classes :
require(stats4)
x <- 0:10; y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xh = 6)  
- sum(dpois(y, lambda=ymax/(1+x/xh), log=TRUE))
fit <- mle(ll)
str(fit)

---

strcapture  
Capture String Tokens into a data.frame

Description

Given a character vector and a regular expression containing capture expressions, `strcapture` will extract the captured tokens into a tabular data structure, such as a data.frame, the type and structure of which is specified by a prototype object. The assumption is that the same number of tokens are captured from every input string.

Usage

`strcapture(pattern, x, proto, perl = FALSE, useBytes = FALSE)`
**Arguments**

- **pattern** The regular expression with the capture expressions.
- **x** A character vector in which to capture the tokens.
- **proto** A `data.frame` or S4 object that behaves like one. See details.
- **perl,useBytes** Arguments passed to `regexec`.

**Details**

The `proto` argument is typically a `data.frame`, with a column corresponding to each capture expression, in order. The captured character vector is coerced to the type of the column, and the column names are carried over to the return value. Any data in the prototype are ignored. See the examples.

**Value**

A tabular data structure of the same type as `proto`, so typically a `data.frame`, containing a column for each capture expression. The column types and names are inherited from `proto`. Cases in `x` that do not match `pattern` have `NA` in every column.

**See Also**

`regexec` and `regmatches` for related low-level utilities.

**Examples**

```r
x <- "chr1:1-1000"
pattern <- "([.\d]+):([\d]+)-([\d]+)"
proto <- data.frame(chr=char(), start=integer(), end=integer())
strcapture(pattern, x, proto)
```

---

**summaryRprof**

**Summarise Output of R Sampling Profiler**

**Description**

Summarise the output of the `Rprof` function to show the amount of time used by different R functions.

**Usage**

```r
summaryRprof(filename = "Rprof.out", chunksize = 5000,
memory = c("none", "both", "tseries", "stats"),
lines = c("hide", "show", "both"),
index = 2, diff = TRUE, exclude = NULL,
basenames = 1)
```
Arguments

filename Name of a file produced by `Rprof()`.
chunksize Number of lines to read at a time.
memory Summaries for memory information. See ‘Memory profiling’ below. Can be abbreviated.
lines Summaries for line information. See ‘Line profiling’ below. Can be abbreviated.
index How to summarize the stack trace for memory information. See ‘Details’ below.
diff If TRUE memory summaries use change in memory rather than current memory.
exclude Functions to exclude when summarizing the stack trace for memory summaries.
basenames Number of components of the path to filenames to display.

Details

This function provides the analysis code for `Rprof` files used by `R CMD Rprof`.

As the profiling output file could be larger than available memory, it is read in blocks of chunksize lines. Increasing chunksize will make the function run faster if sufficient memory is available.

Value

If memory = "none" and lines = "hide", a list with components

by.self A data frame of timings sorted by ‘self’ time.
by.total A data frame of timings sorted by ‘total’ time.
sample.interval The sampling interval.
sampling.time Total time of profiling run.

The first two components have columns ‘self.time’, ‘self.pct’, ‘total.time’ and ‘total.pct’, the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If lines = "show", an additional component is added to the list:

by.line A data frame of timings sorted by source location.

If memory = "both" the same list but with memory consumption in Mb in addition to the timings.
If memory = "tseries" a data frame giving memory statistics over time. Memory usage is in bytes.
If memory = "stats" a by object giving memory statistics by function. Memory usage is in bytes.
If no events were recorded, a zero-row data frame is returned.

Memory profiling

Options other than memory = "none" apply only to files produced by `Rprof(memory.profiling = TRUE)`.

When called with memory.profiling = TRUE, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from `malloc`), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.
With `memory = "both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory = "tseries"` or `memory = "stats"` the index argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With `memory = "tseries"` the index is used to construct labels and may be a vector to give multiple sets of labels. With `memory = "stats"` the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory = "tseries"` and `memory = "stats"` the argument `diff = TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff = FALSE` asks for the memory use at the end of the interval.

**Line profiling**

If the code being run has source reference information retained (via `keep.source = TRUE` in `source` or `KeepSource = TRUE` in a package ‘DESCRIPTION’ file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the `lines` parameter can enable the display.

If `lines = "show"`, line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If `lines = "both"`, line locations will be mixed with function names in a combined display.

**See Also**

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

- `Rprof`
- `tracemem` traces copying of an object via the C function `duplicate`.
- `Rprofmem` is a non-sampling memory-use profiler.
- [https://developer.r-project.org/memory-profiling.html](https://developer.r-project.org/memory-profiling.html)

**Examples**

```r
## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)
## End(Not run)
```

---

**Description**

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.
Usage

Sweave(file, driver = RweaveLatex(),
       syntax = getOption("SweaveSyntax"), encoding = "", ...)

Stangle(file, driver = Rtangle(),
         syntax = getOption("SweaveSyntax"), encoding = "", ...)

Arguments

file          Path to Sweave source file. Note that this can be supplied without the extension,
              but the function will only proceed if there is exactly one Sweave file in the
              directory whose basename matches file.
driver        the actual workhorse, (a function returning) a named list of five functions, see
              ‘Details’ or the Sweave manual vignette.
syntax        NULL or an object of class SweaveSyntax or a character string with its name.
              See the section ‘Syntax Definition’.
encoding      The default encoding to assume for file.
...           further arguments passed to the driver’s setup function: see section ‘Details’,
              or specifically the arguments of the R...Setup() function in RweaveLatex and
              Rtangle, respectively.

Details

Automatic generation of reports by mixing word processing markup (like latex) and S code. The S
code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be
re-generated if the input data change and documents the code to reproduce the analysis in the same
file that also produces the report.

Sweave combines the documentation and code chunks together (or their output) into a single docu-
ment. Stangle extracts only the code from the Sweave file creating an S source file that can be run
using source. (Code inside \Sexpr{} statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can
be used: the CRAN package cacheSweave and the Bioconductor package weaver both provide
drivers based on the default driver RweaveLatex which incorporate ideas of caching the results of
computations on code chunks.

Environment variable SWEAVE_OPTIONS can be used to override the initial options set by the driver:
it should be a comma-separated set of key=value items, as would be used in a ‘\SweaveOpts’
statement in a document.

Non-ASCII source files must contain a line of the form

\usepackage[foo]{inputenc}

(where ‘foo’ is typically ‘latin1’, ‘latin2’, ‘utf8’ or ‘cp1252’ or ‘cp1250’) or they will give an
error. Re-encoding can be turned off completely with argument encoding = "bytes".

Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default
is a noweb-style syntax, as alternative a latex-style syntax can be used. (See the user manual for
further details.)
If syntax = NULL (the default) then the available syntax objects are consulted in turn, and selected if their extension component matches (as a regexp) the file name. Objects SweaveSyntaxNoweb (with extension = "[.][rsRS]nw$") and SweaveSyntaxLatex (with extension = "[.][rsRS]tex$") are supplied, but users or packages can supply others with names matching the pattern SweaveSyntax.*.

RweaveLatex, Rtangle.

Packages cacheSweave, weaver (Bioconductor) and SweaveListingUtils.

Further Sweave drivers are in, for example, packages R2HTML, ascii, odfWeave and pgfSweave.

Non-Sweave vignettes may be built with tools::buildVignette.

Examples

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## enforce par(ask = FALSE)
options(device.ask.default = FALSE)

## create a LaTeX file
Sweave(testfile)

## This can be compiled to PDF by
## tools::texi2pdf("Sweave-test-1.tex")
## or outside R by
## R CMD texi2pdf Sweave-test-1.tex
## which sets the appropriate TEXINPUTS path.

## create an R source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")
SweaveSyntConv

Convert Sweave Syntax

Description

This function converts the syntax of files in Sweave format to another Sweave syntax definition.

Usage

SweaveSyntConv(file, syntax, output = NULL)

Arguments

- **file**: Name of Sweave source file.
- **syntax**: An object of class SweaveSyntax or a character string with its name giving the target syntax to which the file is converted.
- **output**: Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in file are also removed such that the output is created in the current working directory.

Author(s)

Friedrich Leisch

Examples

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
Create a Tar Archive

Description
Create a tar archive.

Usage
```
tar(tarfile, files = NULL, compression = c("none", "gzip", "bzip2", "xz"), compression_level = 6, tar = Sys.getenv("tar"), extra_flags = "")
```

Arguments
- **tarfile**: The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary writes.
- **files**: A character vector of filepaths to be archived: the default is to archive all files under the current directory.
- **compression**: character string giving the type of compression to be used (default none). Can be abbreviated.
- **compression_level**: integer: the level of compression. Only used for the internal method.
- **tar**: character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by `shQuote`) – but argument `tar` can also contain flags separated from the command by spaces.
- **extra_flags**: any extra flags for an external `tar`.

Details
This is either a wrapper for a `tar` command or uses an internal implementation in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (the 'factory-fresh' default). Note that whereas Unix-alike versions of R set the environment variable TAR, its value is not the default for this function.

Argument `extra_flags` is passed to an external tar and so is platform-dependent. Possibly useful values include ‘-h’ (follow symbolic links, also ‘-L’ on some platforms), ‘--acls’, ‘--exclude-backups’, ‘--exclude-vcs’ (and similar) and on Windows ‘--force-local’ (so drives can be included in filepaths: however, this is the default for the Rtools tar). For GNU tar, ‘--format=ustar’ forces a more portable format. (The default is set at compilation and will be shown at the end of the output from `tar --help` for version 1.28 ‘out-of-the-box’ it is ‘--format=gnu’, but the manual says the intention is to change to ‘--format=pax’ which GNU incorrectly calls ‘POSIX’ – it was never part of the POSIX standard for tar and should not be used.) For libarchive’s bsd.tar, ‘--format=ustar’ is more portable than the default.

One issue which can cause an external command to fail is a command line too long for the system shell: as from R 3.5.0 this is worked around if the external command is detected to be GNU tar or libarchive tar (aka bsd.tar).

Note that `files = '.'` will usually not work with an external tar as that would expand the list of files after `tarfile` is created. (It does work with the default internal method.)
Value

The return code from `system` or 0 for the internal version, invisibly.

Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of `pax`, and in any case many common implementations diverged from the former standard. Many R platforms use a version of GNU tar (including `Rtools` on Windows), but the behaviour seems to be changed with each version. OS X >= 10.6 and FreeBSD use `bsdttar` from the ‘libarchive’ project, and commercial Unixes will have their own versions.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of tar, and supported in one way by POSIX tar and in another by GNU tar and yet another by the POSIX pax command which recent tar programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998 POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by `untar`).

Most formats do not record the encoding of file paths.

- (File) links. tar was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but `bsdttar` ignores it. The internal method uses the GNU extension, with a warning.

- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.

- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of nuls), unlike GNU tar which by default pads with ‘nul’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

The ‘ustar’ format records file modification times to a resolution of 1 second: on file systems with higher resolution it is conventional to discard fractional seconds.

Note

For users of macOS (formerly OS X). Apple’s HFS and HFS+ file systems have a legacy concept of ‘resource forks’ dating from classic Mac OS and rarely used nowadays. Apple’s version of tar stores these as separate files in the tarball with names prefixed by ‘._’, and unpacks such files into resource forks (if possible): other ways of unpacking (including `untar` in R) unpack them as separate files.
When argument `tar` is set to the command `tar` on macOS, environment variable `COPYFILE_DISABLE=1` is set, which for the system version of `tar` prevents these separate files being included in the tarball.

toLatex

Converting R Objects to BibTeX or LaTeX

Description

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

Usage

```r
?object, ...
?object, ...
## S3 method for class 'Bibtex'
?object, ...
## S3 method for class 'Latex'
?object, ...
```

Arguments

- `object` object of a class for which a `toBibtex` or `toLatex` method exists.
- `x` object of class "Bibtex" or "Latex".
- `prefix` a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation.
- `...` in the print methods, passed to `writeLines`.

Details

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

See Also

`citEntry` and `sessionInfo` for examples
Description

Text progress bar in the R console.

Usage

```r
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
               width = NA, title, label, style = 1, file = "")
```

```r
getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar'
close(con, ...)
```

Arguments

- `min, max` (finite) numeric values for the extremes of the progress bar. Must have `min < max`.
- `initial, value` initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.
- `char` the character (or character string) to form the progress bar.
- `width` the width of the progress bar, as a multiple of the width of `char`. If `NA`, the default, the number of characters is that which fits into `getOption("width")`.
- `style` the ‘style’ of the bar – see ‘Details’.
- `file` an open connection object or "" which indicates the console: `stderr()` might be useful here.
- `pb, con` an object of class "txtProgressBar".
- `title, label` ignored, for compatibility with other progress bars.
- `...` for consistency with the generic.

Details

`txtProgressBar` will display a progress bar on the R console (or a connection) via a text representation.

`setTxtProgressBar` will update the value. Missing (NA) and out-of-range values of `value` will be (silently) ignored. (Such values of `initial` cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

`style = 1` and `style = 2` just shows a line of `char`. They differ in that `style = 2` redraws the line each time, which is useful if other code might be writing to the R console. `style = 3` marks the end of the range by | and gives a percentage to the right of the bar.
Value
For `txtProgressBar` an object of class "txtProgressBar".
For `getTxtProgressBar` and `setTxtProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTxtProgressBar`).

Note
Using style 2 or 3 or reducing the value with `style = 1` uses '\r' to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when `stdout()` is redirected to a file.

See Also
- `tkProgressBar`.
  Windows versions of R also have `winProgressBar`.

Examples
```r
# slow
testit <- function(x = sort(runif(20)), ...) {
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
```

---

### type.convert

**Convert Data to Appropriate Type**

**Description**
Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

**Usage**
```
type.convert(x, ...)
```

## Default S3 method:
```
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".",
              numerals = c("allow.loss", "warn.loss", "no.loss"), ...)
```

## S3 method for class 'data.frame'
```
type.convert(x, ...)
```

## S3 method for class 'list'
```
type.convert(x, ...)
```
Arguments

- **x**: a vector, matrix, array, data frame, or list.
- **na.strings**: a vector of strings which are to be interpreted as `NA` values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
- **as.is**: whether to convert factors to character vectors. The default is to convert character vectors to factors. See ‘Details’.
- **dec**: the character to be assumed for decimal points.
- **numerals**: string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when `x` has more digits than can be stored in a `double`. Can be abbreviated. Possible values are
  - `numerals = "allow.loss", default`: the conversion happens with some accuracy loss. This was the behavior of R versions 3.0.3 and earlier, and the default from 3.1.1 onwards.
  - `numerals = "warn.loss": a warning about accuracy loss is signalled and the conversion happens as with numerals = "allow.loss".
  - `numerals = "no.loss": x is not converted to a number, but to a factor or character, depending on as.is. This was the behavior of R version 3.1.0.

... arguments to be passed to or from methods.

Details

This helper function is used by `read.table`. When the data object `x` is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and failing that converts a character vector to factor unless `as.is = TRUE`. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since `NA` is primarily logical.

Vectors containing just `F`, `T`, `FALSE`, `TRUE` and values from `na.strings` are converted to logical. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see `NumericConstants`), or `NaN`, `Inf` or `infinity` (ignoring case) or values from `na.strings` are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings (for `as.is = TRUE`) or factors.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

Value

An object like `x` but using another storage mode when appropriate.

Author(s)

R Core, with a contribution by Arni Magnusson

See Also

`read.table`, `class`, `storage.mode`. 
Examples

```r
## Numeric to integer
class(rivers)
x <- type.convert(rivers)
class(x)

## Convert many columns
auto <- type.convert(mtcars)
str(mtcars)
str(auto)

## Convert matrix
phones <- type.convert(WorldPhones)
storage.mode(WorldPhones)
storage.mode(phones)

## Factor or character
chr <- c("A", "B", "B", "A")
fac <- factor(c("A", "B", "B", "A"))
type.convert(chr) # -> factor
type.convert(fac) # -> factor
type.convert(chr, as.is = TRUE) # -> character
type.convert(fac, as.is = TRUE) # -> character
```

untar

Extract or List Tar Archives

Description

Extract files from or list the contents of a tar archive.

Usage

```r
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
      compressed = NA, extras = NULL, verbose = FALSE,
      restore_times = TRUE, tar = Sys.getenv("TAR"))
```

Arguments

tarfile  The pathname of the tar file: tilde expansion (see `path.expand`) will be performed. Alternatively, a connection that can be used for binary reads.

files A character vector of recorded filepaths to be extracted: the default is to extract all files.

list If TRUE, list the files (the equivalent of `tar -tf`). Otherwise extract the files (the equivalent of `tar -xf`).

exdir The directory to extract files to (the equivalent of `tar -C`). It will be created if necessary.

compressed logical or character string. Values "gzip", "bzip2" and "xz" select that form of compression (and may be abbreviated to the first letter). TRUE indicates gzip compression, FALSE no known compression (but an external tar command may detect compression automagically), and NA (the default) indicates that the type is inferred from the file header.
untar

`extras` NULL or a character string: further command-line flags such as `'-p'` to be passed to an external `tar` program.

`verbose` logical: if true echo the command used.

`restore_times` logical. If true (default) restore file modification times. If false, the equivalent of the `'-m'` flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.

Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds).

`tar` character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted – but `tar` can also contain flags separated from the command by spaces.

Details

This is either a wrapper for a `tar` command or for an internal implementation written in R. The latter is used if `tarfile` is a connection or if the argument `tar` is "internal" or "" (except on Windows, when `tar.exe` is tried first).

What options are supported will depend on the `tar` used. Modern GNU flavours of `tar` will support compressed archives, and since 1.15 are able to detect the type of compression automatically: version 1.20 added support for lzma and version 1.22 for xz compression using LZMA2. macOS 10.6 and later (and FreeBSD and some other OSes) have a `tar` (also known as `bsdtar`) from the ‘libarchive’ project which can also detect gzip and bzip2 compression automatically. For other flavours of `tar`, environment variable `R_GZIPCMD` gives the command to decompress gzip and compress files, and `R_BZIPCMD` for bzip2 files.

Arguments `compressed`, `extras` and `verbose` are only used when an external `tar` is used.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses `gzfile` to read a file it can handle files compressed by any of the methods that function can handle: at least compress, gzip, bzip2 and xz compression, and some types of lzma compression. It does not guard against restoring absolute file paths, as some `tar` implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the standard (USTAR/POSIX), GNU and pax ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

```markdown
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a `tar` program that handles it, and look carefully at the resulting files. There may also be the warning

```markdown
using pax extended headers
```

This is indicates that additional information may have been discarded, such as ACLs, encodings ...

The standards only support ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.
The internal implementation does not special-case ‘resource forks’ in macOS: that system’s tar command does. This may lead to unexpected files with names with prefix ‘._’.

Value

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the tar archive. Otherwise the return code from `system` with an external `tar` or `0L`, invisibly.

See Also

tar, unzip.

unzip

Extract or List Zip Archives

Description

Extract files from or list a zip archive.

Usage

`unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE, junkpaths = FALSE, exdir = ".", unzip = "internal", setTimes = FALSE)`

Arguments

`zipfile` The pathname of the zip file: tilde expansion (see `path.expand`) will be performed.

`files` A character vector of recorded filepaths to be extracted: the default is to extract all files.

`list` If `TRUE`, list the files and extract none. The equivalent of `unzip -l`.

`overwrite` If `TRUE`, overwrite existing files, otherwise ignore such files. The equivalent of `unzip -o`.

`junkpaths` If `TRUE`, use only the basename of the stored filepath when extracting. The equivalent of `unzip -j`.

`exdir` The directory to extract files to (the equivalent of `unzip -d`). It will be created if necessary.

`unzip` The method to be used. An alternative is to use `getOption("unzip")`, which on a Unix-alike may be set to the path to a `unzip` program.

`setTimes` logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.)

Value

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class “POSIXct”).

Otherwise for the “internal” method, a character vector of the filepaths extracted to, invisibly.
update.packages

Note

The default internal method is a minimal implementation, principally designed for Windows’ users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in zip 3.0: for that use unzip = "unzip" with unzip 6.00 or later. It does have some support for bzip2 compression and >2GB zip files (but not >=4GB files pre-compression contained in a zip file: like many builds of unzip it may truncate these, in R’s case with a warning if possible).

If unzip specifies a program, the format of the dates listed with list = TRUE is unknown (on Windows it can even depend on the current locale) and the return values could be NA or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from unzip 6.00).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

Source

The internal C code uses zlib and is in particular based on the contributed ’minizip’ application in the zlib sources (from http://zlib.net) by Gilles Vollant.

See Also

unz to read a single component from a zip file.
zip for packing, i.e., the “inverse” of unzip(): further untar and tar, the corresponding pair for (un)packing tar archives (“tarballs”) such as R source packages.

update.packages

Compare Installed Packages with CRAN-like Repositories

Description

old.packages indicates packages which have a (suitable) later version on the repositories whereas update.packages offers to download and install such packages.

new.packages looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

Usage

update.packages(lib.loc = NULL, repos = getOption("repos"),
contriburl = contrib.url(repos, type),
method, instlib = NULL,
ask = TRUE, available = NULL,
oldPkgs = NULL, ..., checkBuilt = FALSE,
type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
contriburl = contrib.url(repos, type),
instPkgs = installed.packages(lib.loc = lib.loc, ...),
method, available = NULL, checkBuilt = FALSE, ..., 
type = getOption("pkgType"))
new.packages(lib.loc = NULL, repos = getOption("repos"),
             contriburl = contrib.url(repos, type),
             instPkgs = installed.packages(lib.loc = lib.loc, ...),
             method, available = NULL, ask = FALSE, ...
             type = getOption("pkgType"))

Arguments

lib.loc character vector describing the location of R library trees to search through (and update packages therein), or NULL for all known trees (see .libPaths).
repos character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as "https://cloud.r-project.org".
contriburl URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument repos. Incompatible with type = "both".
method Download method, see download.file. Unused if a non-NULL available is supplied.
instlib character string giving the library directory where to install the packages.
ask logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. (The latter value only works on systems with a GUI version of select.list, and is otherwise equivalent to ask = TRUE.)
available an object as returned by available.packages listing packages available at the repositories, or NULL which makes an internal call to available.packages. Incompatible with type = "both".
checkBuilt If TRUE, a package built under an earlier major.minor version of R (e.g., 3.4) is considered to be 'old'.
oldPkgs if specified as non-NULL, update.packages() only considers these packages for updating. This may be a character vector of package names or a matrix as returned by old.packages.
instPkgs by default all installed packages, installed.packages(lib.loc = lib.loc). A subset can be specified; currently this must be in the same (character matrix) format as returned by installed.packages().
... Arguments such as destdir and dependencies to be passed to install.packages and ignore_repos_cache, max_repos_cache_age and noCache to available.packages or installed.packages.
type character, indicating the type of package to download and install. See install.packages.

Details

old.packages compares the information from available.packages with that from instPkgs (computed by installed.packages by default) and reports installed packages that have newer versions on the repositories or, if checkBuilt = TRUE, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

1994
**url.show**

Display a Text URL

**Description**

Extension of `file.show` to display text files from a remote server.

**Usage**

```r
url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)
```
Arguments

url  The URL to read from.
title  Title for the browser.
file  File to copy to.
delete.file  Delete the file afterwards?
method  File transfer method: see download.file
...  Arguments to pass to file.show.

Note

Since this is for text files, it will convert to CRLF line endings on Windows.

See Also

url, file.show, download.file

Examples

## Not run: url.show("http://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")

---

**URLencode**

Encode or Decode a (partial) URL

Description

Functions to percent-encode or decode characters in URLs.

Usage

URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)

Arguments

URL  a character string.
reserved  logical: should ‘reserved’ characters be encoded? See ‘Details’.
repeated  logical: should apparently already-encoded URLs be encoded again?

Details

Characters in a URL other than the English alphanumeric characters and ‘- _ . ~’ should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as ‘percent-encoding’.

In addition, ‘! $ & ’ ( ) * + , ; = / ? # [ ]’ are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in URLencode is to leave them alone, which is appropriate for ‘file://’ URLs, but probably not for ‘http://’ ones.

An ‘apparently already-encoded URL’ is one containing %xx for two hexadecimal digits.
Value

A character string.

References

Examples

(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted

utils-deprecated

Deprecated Functions in Package utils

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

Deprecated, Defunct

View

Invoke a Data Viewer

Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

View(x, title)

Arguments

x an R object which can be coerced to a data frame with non-zero numbers of rows and columns.

name title for viewer window. Defaults to name of x prefixed by Data:
Details

Object \( x \) is coerced (if possible) to a data frame, then columns are converted to character using `format.data.frame`. The object is then viewed in a spreadsheet-like data viewer, a read-only version of `data.entry`.

If there are row names on the data frame that are not \( 1:nrow \), they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

The array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

Value

Invisible `NULL`. The functions puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

`edit.data.frame`, `data.entry`.

---

**vignette** | View, List or Get R Source of Package Vignettes

---

Description

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

Usage

```r
vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)
```

```r
## S3 method for class 'vignette'
print(x, ...)
## S3 method for class 'vignette'
edit(name, ...)
```

Arguments

- **topic**
  - a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.

- **package**
  - a character vector with the names of packages to search through, or `NULL` in which ‘all’ packages (as defined by argument `all`) are searched.

- **lib.loc**
  - a character vector of directory names of R libraries, or `NULL`. The default value of `NULL` corresponds to all libraries currently known.

- **all**
  - logical; if `TRUE` search all available packages in the library trees specified by `lib.loc`, and if `FALSE`, search only attached packages.

- **x, name**
  - object of class `vignette`.

- **...**
  - ignored by the `print` method, passed on to `file.edit` by the `edit` method.
warnErrList

Collect and Summarize Errors From List

Description

Collect errors (class "error", typically from tryCatch) from a list `x` into a “summary warning”, by default produce a `warning` and keep that message as "warningMsg" attribute.

Usage

`warnErrList(x, warn = TRUE, errValue = NULL)`
Arguments

**x**
a list, typically from applying models to a list of data (sub)sets, e.g., using `tryCatch(*, error = identity)`.

**warn**
logical indicating if `warning()` should be called.

**errValue**
the value with which errors should be replaced.

Value

a list of the same length and names as the x argument, with the error components replaced by `errValue`, NULL by default, and summarized in the "warningMsg" attribute.

See Also

The `warnErrList()` utility has been used in `lmList()` and `nlsList()` in recommended package `nlme` forever.

Examples

```r
## Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[,"Chick"])
sapply(ChWtgrps, nrow)# typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
                                   lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning :
## 50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors --> all replaced by NULL
nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
                                   lm(weight ~ Time + I(Time^2), data = DAT)))
nl2 <- warnErrList(nlis2)
stopifnot(identical(nl2, nlis2)) # because there was *no* error at all
nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
                                   lm(weight ~ poly(Time, 3), data = DAT)))
nl3 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error"),
          identical(nl3[-1], nlis3[-1]),
          is.null(nl3[[1]]))
)

## With different error messages
if(requireNamespace("nlme")) { # almost always, as it is recommended
data(Soybean, package="nlme")
attr(Soybean, "formula") #-> weight ~ Time | Plot => split by "Plot":
L <- lapply(split(Soybean, Soybean[,"Plot"]),
          function(DD) tryCatch(error = identity,
                             nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
Lw <- warnErrList(L)
} # if <nlme>
```
write.table  

Data Output

Description

write.table prints its required argument \( x \) (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

Usage

\[
\text{write.table}(x, \text{file}=\text{""}, \text{append} = \text{FALSE}, \text{quote} = \text{TRUE}, \text{sep} = \text{""}, \\
\text{eol} = \text{"\n"}, \text{na} = \text{"NA"}, \text{dec} = \text{"."}, \text{row.names} = \text{TRUE}, \\
\text{col.names} = \text{TRUE}, \text{qmethod} = \text{c("escape", "double")}, \\
\text{fileEncoding} = \text{""})
\]

write.csv(...)  
write.csv2(...)

Arguments

- \( x \): the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce \( x \) to a data frame.
- \( \text{file} \): either a character string naming a file or a connection open for writing. \text{""} indicates output to the console.
- \( \text{append} \): logical. Only relevant if \( \text{file} \) is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.
- \( \text{quote} \): a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted.
- \( \text{sep} \): the field separator string. Values within each row of \( x \) are separated by this string.
- \( \text{eol} \): the character(s) to print at the end of each line (row). For example, \text{eol} = \text{"\r\n"} will produce Windows’ line endings on a Unix-alike OS, and \text{eol} = \text{"\r"} will produce files as expected by Excel:mac 2004.
- \( \text{na} \): the string to use for missing values in the data.
- \( \text{dec} \): the string to use for decimal points in numeric or complex columns: must be a single character.
- \( \text{row.names} \): either a logical value indicating whether the row names of \( x \) are to be written along with \( x \), or a character vector of row names to be written.
- \( \text{col.names} \): either a logical value indicating whether the column names of \( x \) are to be written along with \( x \), or a character vector of column names to be written. See the section on ‘CSV files’ for the meaning of \text{col.names} = \text{NA}.
- \( \text{qmethod} \): a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of “escape” (default for \text{write.table}), in which case the quote character is escaped in C style by a backslash, or “double” (default for \text{write.csv} and \text{write.csv2}), in which case it is doubled. You can specify just the initial letter.
write.table

fileEncoding character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See file.

... arguments to write.table: append, col.names, sep, dec and qmethod cannot be altered.

Details

If the table has no columns the rownames will be written only if row.names = TRUE, and vice versa. Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (via as.matrix) and so a character col.names or a numeric quote should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate as.character method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by quote.

The dec argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by I(). Use options("OutDec") to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see options), but with the internal equivalent of digits = 15. For finer control, use format to make a character matrix/data frame, and call write.table on that.

These functions check for a user interrupt every 1000 lines of output.

If file is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. file = file("filename", "wb").

CSV files

By default there is no column name for a column of row names. If col.names = NA and row.names = TRUE a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

read.csv(file = "<filename>", row.names = 1)

write.csv and write.csv2 provide convenience wrappers for writing CSV files. They set sep and dec (see below), qmethod = "double", and col.names to NA if row.names = TRUE (the default) and to TRUE otherwise.

write.csv uses "." for the decimal point and a comma for the separator.

write.csv2 uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change append, col.names, sep, dec or qmethod are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism)
correctly if they are ASCII or UTF-16 (use fileEncoding = "UTF-16LE") or perhaps in the current Windows codepage (e.g., "CP1252"), but the `Text Import Wizard` (from the ‘Data’ tab) allows far more choice of encodings. Excel:mac 2004/8 can import only ‘Macintosh’ (which seems to mean Mac Roman), ‘Windows’ (perhaps Latin-1) and ‘PC-8’ files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 ([https://tools.ietf.org/html/rfc4180](https://tools.ietf.org/html/rfc4180)) for CSV files, which mandates comma as the separator and CRLF line endings. `write.csv` writes compliant files on Windows: use `eol = "\r\n"` on other platforms.

**Note**

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

**See Also**

The ‘R Data Import/Export’ manual.

`read.table`, `write.table`, `write.matrix` in package MASS.

**Examples**

```r
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA, qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")

## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)
```

**zip**

Create Zip Archives

**Description**

A wrapper for an external `zip` command to create zip archives.
zip

Usage

zip(zipfile, files, flags = "-r9X", extras = ",",
    zip = Sys.getenv("R_ZIPCMD", "zip"))

Arguments

zipfile The pathname of the zip file: tilde expansion (see path.expand) will be performed.
files A character vector of recorded filepaths to be included.
flags A character string of flags to be passed to the command: see ‘Details’.
extras An optional character vector: see ‘Details’.
zip A character string specifying the external command to be used.

Details

On a Unix-alike, the default for zip will by default use the value of R_ZIPCMD, which is set in 'etc/Renviron' if an unzip command was found during configuration. On Windows, the default relies on a zip program (for example that from Rtools) being in the path.

The default for flags is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the zip command for other possibilities.

Argument extras can be used to specify -x or -i followed by a list of filepaths to exclude or include.

Value

The status value returned by the external command, invisibly.

See Also

unzip, unz; further, tar and untar for (un)packing tar archives.
Part II
Chapter 15

The KernSmooth package

bkde \hspace{1cm} \textit{Compute a Binned Kernel Density Estimate}

**Description**

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

**Usage**

\[
\text{bkde}(x, \text{kernel} = \text{"normal"}, \text{canonical} = \text{FALSE}, \text{bandwidth}, \text{gridsize} = 401L, \text{range.x}, \text{truncate} = \text{TRUE})
\]

**Arguments**

- **x**: numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **bandwidth**: the kernel bandwidth smoothing parameter. Larger values of bandwidth make smoother estimates, smaller values of bandwidth make less smooth estimates. The default is a bandwidth computed from the variance of x, specifically the 'oversmoothed bandwidth selector' of Wand and Jones (1995, page 61).
- **kernel**: character string which determines the smoothing kernel. \text{kernel} can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
- **canonical**: logical flag: if TRUE, canonically scaled kernels are used.
- **gridsize**: the number of equally spaced points at which to estimate the density.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

2007
Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each \( x \) value in the sample, the kernel is centered on that \( x \) and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding \( y \) value in the output.

Value

a list containing the following components:

\- \( x \) vector of sorted \( x \) values at which the estimate was computed.
\- \( y \) vector of density estimates at the corresponding \( x \).

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate’s variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

References

See Also

density, dpik, hist, ksmooth.

Examples

data(geyser, package="MASS")
x <- geyser$duration
est <- bkde(x, bandwidth=0.25)
plot(est, type="l")
Arguments

- **x**: a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **bandwidth**: numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.
- **gridsize**: vector containing the number of equally spaced points in each direction over which the density is to be estimated.
- **range.x**: a list containing two vectors, where each vector contains the minimum and maximum values of x at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Value

A list containing the following components:

- **x1**: vector of values of the grid points in the first coordinate direction at which the estimate was computed.
- **x2**: vector of values of the grid points in the second coordinate direction at which the estimate was computed.
- **fhat**: matrix of density estimates over the mesh induced by x1 and x2.

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each x1,x2 pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding fhat value in the output.

References

See Also

- `bkde`, `density`, `hist`.

Examples

data(geyser, package="MASS")
x <- cbind(geyser$duration, geyser$waiting)
est <- bkde2D(x, bandwidth=c(0.7, 7))
contour(est$x1, est$x2, est$fhat)
persp(est$fhat)
Compute a Binned Kernel Functional Estimate

Description

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

Usage

bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE, truncate = TRUE)

Arguments

- **x**: numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
- **drv**: order of derivative in the density functional. Must be a non-negative even integer.
- **bandwidth**: the kernel bandwidth smoothing parameter. Must be supplied.
- **gridsize**: the number of equally-spaced points over which binning is performed.
- **range.x**: vector containing the minimum and maximum values of x at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
- **binned**: logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
- **truncate**: logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The density functional of order drv is the integral of the product of the density and its drvth derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

Value

the (scalar) estimated functional.

Background

Estimates of this type were proposed by Sheather and Jones (1991).

References

Examples

```r
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)
```

dpih

Select a Histogram Bin Width

Description

Uses direct plug-in methodology to select the bin width of a histogram.

Usage

```r
dpih(x, scalest = "minim", level = 2L, gridsize = 401L, range.x = range(x), truncate = TRUE)
```

Arguments

- `x`: numeric vector containing the sample on which the histogram is to be constructed.
- `scalest`: estimate of scale.
  - "stdev": standard deviation is used.
  - "iqr": inter-quartile range divided by 1.349 is used.
  - "minim": minimum of "stdev" and "iqr" is used.
- `level`: number of levels of functional estimation used in the plug-in rule.
- `gridsize`: number of grid points used in the binned approximations to functional estimates.
- `range.x`: range over which functional estimates are obtained. The default is the minimum and maximum data values.
- `truncate`: if `truncate` is `TRUE` then observations outside of the interval specified by `range.x` are omitted. Otherwise, they are used to weight the extreme grid points.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bin width.

Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

hist

Examples

data(geyser, package="MASS")
x <- geyser$duration
h <- dpik(x)
bins <- seq(min(x)-h, max(x)+h, by=h)
hist(x, breaks=bins)

---

dpink

Select a Bandwidth for Kernel Density Estimation

Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

dpink(x, scalest = "minim", level = 2L, kernel = "normal",
       canonical = FALSE, gridsize = 401L, range.x = range(x),
       truncate = TRUE)

Arguments

- **x**: numeric vector containing the sample on which the kernel density estimate is to be constructed.
- **scalest**: estimate of scale. 
  - "stdev" - standard deviation is used.
  - "iqr" - inter-quartile range divided by 1.349 is used.
  - "minim" - minimum of "stdev" and "iqr" is used.
- **level**: number of levels of functional estimation used in the plug-in rule.
- **kernel**: character string which determines the smoothing kernel. kernel can be:
  - "normal" - the Gaussian density function (the default).
  - "box" - a rectangular box.
  - "epanech" - the centred beta(2,2) density.
  - "biweight" - the centred beta(3,3) density.
  - "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation.
- **canonical**: logical flag: if TRUE, canonically scaled kernels are used
- **gridsize**: the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.
dpill

range.x vector containing the minimum and maximum values of \(x\) at which to compute the estimate. The default is the minimum and maximum data values.

truncate logical flag: if TRUE, data with \(x\) values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

References

See Also

bkde, density, ksmooth

x <- geyser$duration
h <- dpik(x)
est <- bkde(x, bandwidth=h)
plot(est, type="l")

---

dpill Select a Bandwidth for Local Linear Regression

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05, 
gridsize = 401L, range.x, truncate = TRUE)
Arguments

- **x** numeric vector of x data. Missing values are not accepted.
- **y** numeric vector of y data. This must be same length as x, and missing values are not accepted.
- **blockmax** the maximum number of blocks of the data for construction of an initial parametric estimate.
- **divisor** the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
- **trim** the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
- **proptrun** the proportion of the range of x at each end truncated in the functional estimates.
- **gridsize** number of equally-spaced grid points over which the function is to be estimated.
- **range.x** vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
- **truncate** logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallow’s $C_p$ is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

h <- dpill(x, y)
fit <- locpoly(x, y, bandwidth = h)
lines(fit)

locpoly

Estimate Functions Using Local Polynomials

Description

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

Usage

locpoly(x, y, drv = 0L, degree, kernel = "normal",
bandwidth, gridsize = 401L, bwdisc = 25,
range.x, binned = FALSE, truncate = TRUE)

Arguments

x numeric vector of x data. Missing values are not accepted.
bandwidth the kernel bandwidth smoothing parameter. It may be a single number or an array having length gridsize, representing a bandwidth that varies according to the location of estimation.
y vector of y data. This must be same length as x, and missing values are not accepted.
drv order of derivative to be estimated.
degree degree of local polynomial used. Its value must be greater than or equal to the value of drv. The default value is of degree is drv + 1.
kernel "normal" - the Gaussian density function. Currently ignored.
gridsize number of equally-spaced grid points over which the function is to be estimated.
bwdisc number of logarithmically-equally-spaced bandwidths on which bandwidth is discretised, to speed up computation.
range.x vector containing the minimum and maximum values of x at which to compute the estimate.
binned logical flag: if TRUE, then x and y are taken to be grid counts rather than raw data.
truncate logical flag: if TRUE, data with x values outside the range specified by range.x are ignored.
Value

if y is specified, a local polynomial regression estimate of E[Y|X] (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

- x: vector of sorted x values at which the estimate was computed.
- y: vector of smoothed estimates for either the density or the regression at the corresponding x.

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length gridsize.

<table>
<thead>
<tr>
<th>abbey</th>
<th>Determinations of Nickel Content</th>
</tr>
</thead>
</table>

**Description**

A numeric vector of 31 determinations of nickel content (ppm) in a Canadian syenite rock.

**Usage**

`abbey`

**Source**

**References**

---

<table>
<thead>
<tr>
<th>accdeaths</th>
<th>Accidental Deaths in the US 1973-1978</th>
</tr>
</thead>
</table>

**Description**

A regular time series giving the monthly totals of accidental deaths in the USA.

**Usage**

`accdeaths`

**Details**

The values for first six months of 1979 (p. 326) were 7798 7406 8363 8460 9217 9316.
addterm

Try All One-Term Additions to a Model

**Description**

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

```r
addterm(object, ...)  
```

### Default S3 method:

```r
addterm(object, scope, scale = 0, test = c("none", "Chisq"),  
        k = 2, sorted = FALSE, trace = FALSE, ...)
```

### S3 method for class 'lm'

```r
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
        k = 2, sorted = FALSE, ...)
```

### S3 method for class 'glm'

```r
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
        k = 2, sorted = FALSE, trace = FALSE, ...)
```

**Arguments**

- `object`: An object fitted by some model-fitting function.
- `scope`: a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
- `scale`: used in the definition of the AIC statistic for selecting the models, currently only for `lm`, `aov` and `glm` models. Specifying `scale` asserts that the residual standard error or dispersion is known.
- `test`: should the results include a test statistic relative to the original model? The F test is only appropriate for `lm` and `aov` models, and perhaps for some over-dispersed `glm` models. The Chisq test can be an exact test (`lm` models with known scale) or a likelihood-ratio test depending on the method.
- `k`: the multiple of the number of degrees of freedom used for the penalty. Only `k=2` gives the genuine AIC: `k = log(n)` is sometimes referred to as BIC or SBC.
- `sorted`: should the results be sorted on the value of AIC?
- `trace`: if `TRUE` additional information may be given on the fits as they are tried.
- `...`: arguments passed to or from other methods.
Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

house.glm0 <- glm(Freq ~ Infl*Type*Cont + Sat, family=poisson, data=housing)
addterm(house.glm0, . ~ . + Sat:(Infl+Type+Cont), test="Chisq")
house.glm1 <- update(house.glm0, . ~ . + Sat*(Infl+Type+Cont))
addterm(house.glm1, . ~ . + Sat:(Infl+Type+Cont)^2, test = "Chisq")

Description

Australian AIDS Survival Data

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

Usage

Aids2

Format

This data frame contains 2843 rows and the following columns:

state  Grouped state of origin: "NSW" includes ACT and "other" is WA, SA, NT and TAS.
sex  Sex of patient.
diag (Julian) date of diagnosis.
death (Julian) date of death or end of observation.
status "A" (alive) or "D" (dead) at end of observation.
T.categ Reported transmission category.
age Age (years) at diagnosis.
2020

Animals

Note
This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

Animals  Brain and Body Weights for 28 Species

Description
Average brain and body weights for 28 species of land animals.

Usage
Animals

Format
body  body weight in kg.
brain  brain weight in g.

Note
The name Animals avoids conflicts with a system dataset animals in S-PLUS 4.5 and later.

Source

References
Description

The anorexia data frame has 72 rows and 3 columns. Weight change data for young female anorexia patients.

Usage

anorexia

Format

This data frame contains the following columns:

- Treat: Factor of three levels: "Cont" (control), "CBT" (Cognitive Behavioural treatment) and "FT" (family treatment).
- Prewt: Weight of patient before study period, in lbs.
- Postwt: Weight of patient after study period, in lbs.

Source

(Note that the original source mistakenly says that weights are in kg.)

References

Description

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

Usage

## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
Arguments

object: Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of glm.nb().

...: Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.

test: Argument to match the test argument of anova.glm. Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function anova() for class "negbin". It can be invoked by calling anova(x) for an object x of the appropriate class, or directly by calling anova.negbin(x) regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The theta parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case theta is assumed to have been re-estimated for each model.

glm.nb, negative.binomial, summary.negbin

Examples

m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)

area

Adaptive Numerical Integration

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
Arguments

- **f**: The integrand as an S function object. The variable of integration must be the first argument.
- **a**: Lower limit of integration.
- **b**: Upper limit of integration.
- **...**: Additional arguments needed by the integrand.
- **fa**: Function value at the lower limit.
- **fb**: Function value at the upper limit.
- **limit**: Limit on the depth to which recursion is allowed to go.
- **eps**: Error tolerance to control the process.

Details

The method divides the interval in two and compares the values given by Simpson’s rule and the trapezium rule. If these are within eps of each other the Simpson’s rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

Value

The integral from a to b of f(x).

References

Examples

```r
area(sin, 0, pi) # integrate the sin function from 0 to pi.
```

bacteria

### Presence of Bacteria after Drug Treatments

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

Usage

```r
bacteria
```

Format

This data frame has 220 rows and the following columns:

- **y**: presence or absence: a factor with levels `n` and `y`.
- **ap**: active/placebo: a factor with levels `a` and `p`.
- **hilo**: hi/low compliance: a factor with levels `hi` and `lo`.
- **week**: numeric: week of test.
- **ID**: subject ID: a factor.
- **trt**: a factor with levels `placebo`, `drug` and `drug+`, a re-coding of `ap` and `hilo`.  

Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

    family = binomial, data = bacteria))
```

Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

Usage

`bandwidth.nrd(x)`
bcv

Arguments

\(x\)  
A data vector.

Value

A bandwidth on a scale suitable for the \texttt{width} argument of \texttt{density}.

References

Examples

# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}

bcv \hspace{1cm} \textit{Biased Cross-Validation for Bandwidth Selection}

Description

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

bcv(x, nb = 1000, lower, upper)

Arguments

\(x\)  
a numeric vector

\(nb\)  
number of bins to use.

\(lower, upper\)  
Range over which to minimize. The default is almost always satisfactory.

Value

a bandwidth

beav1  

*Body Temperature Series of Beaver 1*

Description

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

Usage

beav1

Format

The `beav1` data frame has 114 rows and 4 columns. This data frame contains the following columns:

- **day**  Day of observation (in days since the beginning of 1990), December 12–13.
- **time**  Time of observation, in the form 0330 for 3.30am.
- **temp**  Measured body temperature in degrees Celsius.
- **activ** Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing.

Biopsy Data on Breast Cancer Patients

Description

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

Usage

biopsy

Format

This data frame contains the following columns:

- **ID** sample code number (not unique).
- **V1** clump thickness.
- **V2** uniformity of cell size.
- **V3** uniformity of cell shape.
- **V4** marginal adhesion.
- **V5** single epithelial cell size.
- **V6** bare nuclei (16 values are missing).
- **V7** bland chromatin.
- **V8** normal nucleoli.
- **V9** mitoses.
- **class** "benign" or "malignant".

birthwt  

Risk Factors Associated with Low Infant Birth Weight

Description

The *birthwt* data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

Usage

*birthwt*

Format

This data frame contains the following columns:

- **low**: indicator of birth weight less than 2.5 kg.
- **age**: mother’s age in years.
- **lwt**: mother’s weight in pounds at last menstrual period.
- **race**: mother’s race (1 = white, 2 = black, 3 = other).
- **smoke**: smoking status during pregnancy.
- **ptl**: number of previous premature labours.
- **ht**: history of hypertension.
- **ui**: presence of uterine irritability.
- **ftv**: number of physician visits during the first trimester.
- **bwt**: birth weight in grams.

Source

References

Examples

```r
bwt <- with(birthwt, {
  race <- factor(race, labels = c("white", "black", "other"))

  levels(ftv)[-(1:2)] <- "2+
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
              ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```
**Boston Housing Values in Suburbs of Boston**

**Description**

The Boston data frame has 506 rows and 14 columns.

**Usage**

Boston

**Format**

This data frame contains the following columns:

- **crim**  per capita crime rate by town.
- **zn**  proportion of residential land zoned for lots over 25,000 sq.ft.
- **indus**  proportion of non-retail business acres per town.
- **chas**  Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).
- **nox**  nitrogen oxides concentration (parts per 10 million).
- **rm**  average number of rooms per dwelling.
- **age**  proportion of owner-occupied units built prior to 1940.
- **dis**  weighted mean of distances to five Boston employment centres.
- **rad**  index of accessibility to radial highways.
- **tax**  full-value property-tax rate per \$10,000.
- **ptratio**  pupil-teacher ratio by town.
- **black**  $1000(Bk - 0.63)^2$ where $Bk$ is the proportion of blacks by town.
- **lstat**  lower status of the population (percent).
- **medv**  median value of owner-occupied homes in \$1000s.

**Source**

**Box-Cox Transformations for Linear Models**

**Description**
Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

**Usage**

```r
boxcox(object, ...)  
## Default S3 method:  
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
       interp, eps = 1/50, xlab = expression(lambda),  
       ylab = "log-Likelihood", ...)  
## S3 method for class 'formula'  
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
       interp, eps = 1/50, xlab = expression(lambda),  
       ylab = "log-Likelihood", ...)  
## S3 method for class 'lm'  
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,  
       interp, eps = 1/50, xlab = expression(lambda),  
       ylab = "log-Likelihood", ...)  
```

**Arguments**

- `object` a formula or fitted model object. Currently only `lm` and `aov` objects are handled.
- `lambda` vector of values of lambda – default (-2, 2) in steps of 0.1.
- `plotit` logical which controls whether the result should be plotted.
- `interp` logical which controls whether spline interpolation is used. Default to TRUE if plotting with lambda of length less than 100.
- `eps` Tolerance for lambda = 0; defaults to 0.02.
- `xlab` defaults to "lambda".
- `ylab` defaults to "log-Likelihood".
- `...` additional parameters to be used in the model fitting.

**Value**
A list of the lambda vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

**Side Effects**
If `plotit = TRUE` plots log-likelihood vs lambda and indicates a 95% confidence interval about the maximum observed value of lambda. If `interp = TRUE`, spline interpolation is used to give a smoother plot.
cabbages

Cars93  

Data from 93 Cars on Sale in the USA in 1993

Description

The *Cars93* data frame has 93 rows and 27 columns.

Usage

Cars93
Format

This data frame contains the following columns:

- **Manufacturer**
- **Model**
- **Type**: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".
- **Min.Price**: Minimum Price (in \$1,000): price for a basic version.
- **Price**: Midrange Price (in \$1,000): average of Min.Price and Max.Price.
- **Max.Price**: Maximum Price (in \$1,000): price for “a premium version”.
- **MPG.city**: City MPG (miles per US gallon by EPA rating).
- **MPG.highway**: Highway MPG.
- **AirBags**: Air Bags standard. Factor: none, driver only, or driver & passenger.
- **DriveTrain**: Drive train type: rear wheel, front wheel or 4WD; (factor).
- **Cylinders**: Number of cylinders (missing for Mazda RX-7, which has a rotary engine).
- **EngineSize**: Engine size (litres).
- **Horsepower**: Horsepower (maximum).
- **RPM**: RPM (revs per minute at maximum horsepower).
- **Rev.per.mile**: Engine revolutions per mile (in highest gear).
- **Man.trans.avail**: Is a manual transmission version available? (yes or no, Factor).
- **Fuel.tank.capacity**: Fuel tank capacity (US gallons).
- **Passengers**: Passenger capacity (persons).
- **Length**: Length (inches).
- **Wheelbase**: Wheelbase (inches).
- **Width**: Width (inches).
- **Turn.circle**: U-turn space (feet).
- **Rear.seat.room**: Rear seat room (inches) (missing for 2-seater vehicles).
- **Luggage.room**: Luggage capacity (cubic feet) (missing for vans).
- **Weight**: Weight (pounds).
- **Origin**: Of non-USA or USA company origins? (factor).
- **Make**: Combination of Manufacturer and Model (character).

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once. Further description can be found in Lock (1993).

cement  Heat Evolved by Setting Cements

Description
Experiment on the heat evolved in the setting of each of 13 cements.

Usage
cement

Format
- x1, x2, x3, x4  Proportions (%) of active ingredients.
- y  heat evolved in cals/gm.

Details
Thirteen samples of Portland cement were set. For each sample, the percentages of the four main chemical ingredients was accurately measured. While the cement was setting the amount of heat evolved was also measured.

**con2tr**

*Convert Lists to Data Frames for use by lattice*

**Description**

Convert lists to data frames for use by lattice.

**Usage**

con2tr(obj)

**Arguments**

- **obj**

  A list of components x, y and z as passed to contour.

**Details**

con2tr repeats the x and y components suitably to match the vector z.
Confidence Intervals for Model Parameters

Description
Computes confidence intervals for one or more parameters in a fitted model. Package MASS adds methods for glm and nls fits.

Usage
```r
## S3 method for class 'glm'
confint(object, parm, level = 0.95, trace = FALSE, ...)
## S3 method for class 'nls'
confint(object, parm, level = 0.95, ...)
```

Arguments
- `object`: a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.
- `parm`: a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
- `level`: the confidence level required.
- `trace`: logical. Should profiling be traced?
- `...`: additional argument(s) for methods.

Details
`confint` is a generic function in package stats.

These confint methods call the appropriate profile method, then find the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value
A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as (1 - level)/2 and 1 - (1 - level)/2 in % (by default 2.5% and 97.5%).

confint(budworm.lg0)
confint(budworm.lg0, "ldose")

contr.sdif

Successive Differences Contrast Coding

Description

A coding for factors based on successive differences.

Usage

contr.sdif(n, contrasts = TRUE, sparse = FALSE)

Arguments

n

  The number of levels required.

contrasts

  logical: Should there be n - 1 columns orthogonal to the mean (the default) or
  n columns spanning the space?
sparse logical. If true and the result would be sparse (only true for contrasts = FALSE), return a sparse matrix.

Details
The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

Value
If contrasts is TRUE, a matrix with n rows and n - 1 columns, and the n by n identity matrix if contrasts is FALSE.

---

**corresp**

*Simple Correspondence Analysis*

**Description**
Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

**Usage**

```r
corresp(x, ...)  
## S3 method for class 'matrix'
corresp(x, nf = 1, ...)
## S3 method for class 'factor'
corresp(x, y, ...)
## S3 method for class 'data.frame'
corresp(x, ...)
## S3 method for class 'xtabs'
corresp(x, ...)
## S3 method for class 'formula'
corresp(formula, data, ...)
```

**Arguments**
- `x, formula` The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class "xtabs" and formulae of the form ~ F1 + F2, where F1 and F2 are factors.
- `nf` The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.
- `y` a second factor for a cross-classification.
- `data` a data frame against which to preferentially resolve variables in the formula.
- `...` If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.
Details

See Venables & Ripley (2002). The plot method produces a graphical representation of the table if nf=1, with the areas of circles representing the numbers of points. If nf is two or more the biplot method is called, which plots the second and third columns of the matrices $A = Dr^{(-1/2)} U L$ and $B = Dc^{(-1/2)} V L$ where the singular value decomposition is $U L V$. Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does not have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

Value

An list object of class “correspondence” for which print, plot and biplot methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

cov.rob

Resistant Estimation of Multivariate Location and Scatter

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. cov.mve and cov.mcd are compatibility wrappers.

Usage

cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
  method = c("mve", "mcd", "classical"),
  nsamp = "best", seed)
cov.mve(...)
cov.mcd(...)

**cov.rob**

**Arguments**

- **x**: a matrix or data frame.
- **cor**: should the returned result include a correlation matrix?
- **quantile.used**: the minimum number of the data points regarded as good points.
- **method**: the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using `cov.mve` or `cov.mcd` forces `mve` or `mcd` respectively.
- **nsamp**: the number of samples or "best" or "exact" or "sample". If "sample" the number chosen is \(\min(5*p, 3000)\), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted however many samples are needed.
- **seed**: the seed to be used for random sampling: see `RNGkind`. The current value of `.Random.seed` will be preserved if it is set.
- **...**: arguments to `cov.rob` other than `method`.

**Details**

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be good. The final estimates are the mean and rescaled covariance of the good points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an ad hoc finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of \(p\) of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

**Value**

A list with components

- **center**: the final estimate of location.
- **cov**: the final estimate of scatter.
- **cor**: (only is cor = TRUE) the estimate of the correlation matrix.
- **sing**: message giving number of singular samples out of total
- **crit**: the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
- **best**: the subset used. For MVE the best sample, for MCD the best set of size `quantile.used`.
- **n.obs**: total number of observations.

cov.trob Covariance Estimation for Multivariate t Distribution

Description

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

Usage

cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
maxit = 25, tol = 0.01)

Arguments

x data matrix. Missing values (NAs) are not allowed.
wt A vector of weights for each case: these are treated as if the case i actually occurred wt[i] times.
cor Flag to choose between returning the correlation (cor = TRUE) or covariance (cor = FALSE) matrix.
center a logical value or a numeric vector providing the location about which the covariance is to be taken. If center = FALSE, no centering is done; if center = TRUE the MLE of the location vector is used.
nu ‘degrees of freedom’ for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
maxit Maximum number of iterations in fitting.
tol Convergence tolerance for fitting.
Value
A list with the following components

- **cov**: the fitted covariance matrix.
- **center**: the estimated or specified location vector.
- **wt**: the specified weights: only returned if the `wt` argument was given.
- **n.obs**: the number of cases used in the fitting.
- **cor**: the fitted correlation matrix: only returned if `cor = TRUE`.
- **call**: The matched call.
- **iter**: The number of iterations used.

`crabs`  
*Morphological Measurements on Leptograpsus Crabs*

Description

The `crabs` data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

Usage

`crabs`

Format

This data frame contains the following columns:

- `sp`: species - "B" or "O" for blue or orange.
- `sex`: as it says.
- `index`: index 1:50 within each of the four groups.
- `FL`: frontal lobe size (mm).
- `RW`: rear width (mm).
- `CW`: carapace length (mm).
- `BD`: body depth (mm).

**Denumerate**

*Transform an Allowable Formula for `loglm` into one for `terms`*

**Description**

`loglm` allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that `terms` can process.

**Usage**

denumerate(x)

**Arguments**

x A formula conforming to the conventions of `loglm`, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

**Details**

The model fitting function `loglm` fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, … for the first, second, third, … margins in a similar way to variable names. As the model formula has to be parsed by `terms`, which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely n is replaced by .vn. This allows `terms` to parse the formula in the usual way.
Value

A linear model formula like that presented, except that where dimension numbers, say n, have been used to specify fixed margins these are replaced by names of the form .vn which may be processed by terms.

Examples

denumerate(~(1+2+3)^3 + a/b)
## which gives ~ (.v1 + .v2 + .v3)^3 + a/b

dose.p

Predict Doses for Binomial Assay model

Description

Calibrate binomial assays, generalizing the calculation of LD50.

Usage

dose.p(obj, cf = 1:2, p = 0.5)

Arguments

obj A fitted model object of class inheriting from "glm".

cf The terms in the coefficient vector giving the intercept and coefficient of (log-)
dose

p Probabilities at which to predict the dose needed.

Value

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

References

Examples

ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)

**drivers**

*Deaths of Car Drivers in Great Britain 1969-84*

**Description**

A regular time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983.

**Usage**

```r
drivers
```

**Source**

**References**

---

**dropterm**

*Try All One-Term Deletions from a Model*

**Description**

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

```r
dropterm(object, ...)  
## Default S3 method:  
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),  
    k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'  
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
    k = 2, sorted = FALSE, ...)  

## S3 method for class 'glm'  
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),  
    k = 2, sorted = FALSE, trace = FALSE, ...)  
```
Arguments

object
A object fitted by some model-fitting function.

scope
a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.

scale
used in the definition of the AIC statistic for selecting the models, currently only for \texttt{lm}, \texttt{aov} and \texttt{glm} models. Specifying scale asserts that the residual standard error or dispersion is known.

test
should the results include a test statistic relative to the original model? The F test is only appropriate for \texttt{lm} and \texttt{aov} models, and perhaps for some over-dispersed \texttt{glm} models. The Chisq test can be an exact test (\texttt{lm} models with known scale) or a likelihood-ratio test depending on the method.

k
the multiple of the number of degrees of freedom used for the penalty. Only \( k = 2 \) gives the genuine AIC: \( k = \log(n) \) is sometimes referred to as BIC or SBC.

sorted
should the results be sorted on the value of AIC?

trace
if TRUE additional information may be given on the fits as they are tried.

... arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (\texttt{lm} models with specified scale) the constant is taken to be that used in Mallows’ Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

dropterm(eagles.glm)
prof <- profile(eagles.glm)
plot(prof)
pairs(prof)
```
Description
Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject’s age is the only covariate.

Usage
epil

Format
This data frame has 236 rows and the following 9 columns:
y the count for the 2-week period.
trt treatment, “placebo” or “progabide”.
base the counts in the baseline 8-week period.
age subject’s age, in years.
V4 0/1 indicator variable of period 4.
subject subject number, 1 to 59.
period period, 1 to 4.
lbase log-counts for the baseline period, centred to have zero mean.
lage log-ages, centred to have zero mean.

eqscplot

Plots with Geometrically Equal Scales

Description

Version of a scatterplot with scales chosen to be equal on both axes, that is 1 cm represents the same units on each

Usage

eqscplot(x, y, ratio = 1, tol = 0.04, uin, ...)

Arguments

x
    vector of x values, or a 2-column matrix, or a list with components x and y

y
    vector of y values

ratio
    desired ratio of units on the axes. Units on the y axis are drawn at ratio times the size of units on the x axis. Ignored if uin is specified and of length 2.

tol
    proportion of white space at the margins of plot

uin
    desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.

... further arguments for plot and graphical parameters. Note that par(xaxs="i", yaxs="i") is enforced, and xlim and ylim will be adjusted accordingly.

Details

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by ratio. Finally both are stretched by 1 + tol to move points away from the axes, and the points plotted.

Value

invisibly, the values of uin used for the plot.

Side Effects

performs the plot.
Note
Arguments ratio and uin were suggested by Bill Dunlap.

farms

Ecological Factors in Farm Management

Description
The farms data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

Usage
farms

Format
This data frame contains the following columns:
- Mois Five levels of soil moisture – level 3 does not occur at these 20 farms.
- Manag Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).
- Use Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing).
- Manure Manure usage – classes C0 to C4.

Source
Quoted as from:

Examples
```r
courts.mca <- mca(farms, abbrev = TRUE)  # Use levels as names
eqscplot(farms.mca$cs, type = "n")
text(farms.mca$rs, cex = 0.7)
text(farms.mca$cs, labels = dimnames(farms.mca$cs)[[1]], cex = 0.7)
```
The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

**Usage**

`fgl`

**Format**

This data frame contains the following columns:

- **RI** refractive index; more precisely the refractive index is 1.518xxxx.
- The next 8 measurements are percentages by weight of oxides.
  - Na sodium.
  - Mg manganese.
  - Al aluminium.
  - Si silicon.
  - K potassium.
  - Ca calcium.
  - Ba barium.
  - Fe iron.
- **type** The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (WinF: 70), window non-float glass (WinNF: 76), vehicle window glass (Veh: 17), containers (Con: 13), tableware (Tabl: 9) and vehicle headlamps (Head: 29).

**References**

**Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

`fitdistr(x, densfun, start, ...)`
Arguments

`x`  A numeric vector of length at least one containing only finite values.

densfun  Either a character string or a function returning a density evaluated at its first argument.

Distributions  "beta", "cauchy", "chi-squared", "exponential", "f", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.

`start`  A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).

...  Additional parameters, either for densfun or for optim. In particular, it can be used to specify bounds via `lower` or `upper` or both. If arguments of densfun (or the density function corresponding to a character-string specification) are included they will be held fixed.

Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and `start` should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using `optim`. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named `lower` or `upper` are supplied (when L-BFGS-B is used) or method is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location `m` and scale `s`.

For the following named distributions, reasonable starting values will be computed if `start` is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by `mu` and `size`), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are `print`, `coef`, `vcov` and `logLik` methods for class "fitdistr".

Value

An object of class "fitdistr", a list with four components,

- `estimate`  the parameter estimates,
- `sd`  the estimated standard errors,
- `vcov`  the estimated variance-covariance matrix, and
- `loglik`  the log-likelihood.

Note

Numerical optimization cannot work miracles: please note the comments in `optim` on scaling data.

If the fitted parameters are far away from one, consider re-fitting specifying the control parameter `parscale`.

## Examples

```r
## avoid spurious accuracy
op <- options(digits = 3)
set.seed(123)
x <- rgamma(100, shape = 5, rate = 0.1)
fitdistr(x, "gamma")
## now do this directly with more control.
fitdistr(x, dgamma, list(shape = 1, rate = 0.1), lower = 0.001)

set.seed(123)
x2 <- rt(250, df = 9)
fitdistr(x2, "t", df = 9)
## allow df to vary: not a very good idea!
fitdistr(x2, "t")
## now do fixed-df fit directly with more control.
mydt <- function(x, m, s, df) dt((x-m)/s, df)/s
fitdistr(x2, mydt, list(m = 0, s = 1), df = 9, lower = c(-Inf, 0))

set.seed(123)
x3 <- rweibull(100, shape = 4, scale = 100)
fitdistr(x3, "weibull")

set.seed(123)
x4 <- rnegbin(500, mu = 5, theta = 4)
fitdistr(x4, "Negative Binomial")
options(op)
```

### forbes

**Forbes’ Data on Boiling Points in the Alps**

## Description

A data frame with 17 observations on boiling point of water and barometric pressure in inches of mercury.

## Usage

```r
forbes
```

## Format

- **bp**: boiling point (degrees Fahrenheit).
- **pres**: barometric pressure in inches of mercury.

## Source

fractions

Rational Approximation

Description
Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage
fractions(x, cycles = 10, max.denominator = 2000, ...)

Arguments
- x: Any object of mode numeric. Missing values are now allowed.
- cycles: The maximum number of steps to be used in the continued fraction approximation process.
- max.denominator: An early termination criterion. If any partial denominator exceeds max.denominator the continued fraction stops at that point.
- ...: arguments passed to or from other methods.

Details
Each component is first expanded in a continued fraction of the form
\[ x = \text{floor}(x) + \frac{1}{(p_1 + \frac{1}{p_2 + \ldots})} \]
where \( p_1, p_2, \ldots \) are positive integers, terminating either at cycles terms or when a \( p_j > \text{max.denominator} \). The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

Value
An object of class "fractions". A structure with .Data component the same as the input numeric x, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

References

See Also
rational
Examples

```r
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
fractions(solve(X, X/5))
fractions(solve(X, X/5)) + 1
```

GAGurine  
**Level of GAG in Urine of Children**

Description

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrican to assess if a child’s GAG concentration is ‘normal’.

Usage

GAGurine

Format

This data frame contains the following columns:

- **Age** age of child in years.
- **GAG** concentration of GAG (the units have been lost).

Source

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

References

Galaxies

**Velocities for 82 Galaxies**

Description

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

Usage

galaxies
Note

There is an 83rd measurement of 5607 km/sec in the Postman et al. paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

Source

References

Examples

gal <- galaxies/1000
c(width.SJ(gal, method = "dpi"), width.SJ(gal))
plot(x = c(0, 40), y = c(0, 0.3), type = "n", bty = "l",
     xlab = "velocity of galaxy (1000km/s)", ylab = "density")
rug(gal)
lines(density(gal, width = 3.25, n = 200), lty = 1)
lines(density(gal, width = 2.56, n = 200), lty = 3)

gamma.dispersion  Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit

description

A front end to gamma.shape for convenience. Finds the reciprocal of the estimate of the shape parameter only.

Usage

gamma.dispersion(object, ...)

Arguments

object  Fitted model object giving the gamma fit.
...

Addional arguments passed on to gamma.shape.

Value

The MLE of the dispersion parameter of the gamma distribution.

References

gamma.shape

Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit

Description

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

Usage

```r
## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
            eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

Arguments

- `object`: Fitted model object from a Gamma family or quasi family with variance = "mu^2".
- `it.lim`: Upper limit on the number of iterations.
- `eps.max`: Maximum discrepancy between approximations for the iteration process to continue.
- `verbose`: If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.
- `...`: Further arguments passed to or from other methods.

Details

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

Value

List of two components

- `alpha`: the maximum likelihood estimate
- `SE`: the approximate standard error, the square-root of the reciprocal of the observed information.

    lot2 = c(69,35,26,21,18,16,13,12,12))
clot1 <- glm(lot1 ~ log(u), data = clotting, family = Gamma)
gamma.shape(clot1)

gm <- glm(Days + 0.1 ~ Age*Eth*Sex*Lrn, quasi(link=log, variance="mu^2"), quine,
    start = c(3, rep(0,31)))
gamma.shape(gm, verbose = TRUE)
summary(gm, dispersion = gamma.dispersion(gm)) # better summary

gehan  

Remission Times of Leukaemia Patients

Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug 6-mercaptopurine and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

Usage

gehan

Format

This data frame contains the following columns:

time remission time in weeks.
cens censoring, 0/1.
treat treatment, control or 6-MP.

Source

References

Examples

```r
library(survival)
gehan.surv <- survfit(Surv(time, cens) ~ treat, data = gehan,
    conf.type = "log-log")
summary(gehan.surv)
survreg(Surv(time, cens) ~ factor(pair) + treat, gehan, dist = "exponential")
summary(survreg(Surv(time, cens) ~ treat, gehan, dist = "exponential"))
summary(survreg(Surv(time, cens) ~ treat, gehan))
gehan.cox <- coxph(Surv(time, cens) ~ treat, gehan)
summary(gehan.cox)
```

### Rat Genotype Data

#### Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

#### Usage

```r
genotype
```

#### Format

The data frame has the following components:

- **Litter** genotype of the litter.
- **Mother** genotype of the foster mother.
- **Wt** Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

#### Source

**Old Faithful Geyser Data**

**Description**

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

**Usage**

geyser

**Format**

A data frame with 299 observations on 2 variables.

- **duration** numeric Eruption time in mins
- **waiting** numeric Waiting time for this eruption

**Note**

The waiting time was incorrectly described as the time to the next eruption in the original files, and corrected for MASS version 7.3-30.

**Line Transect of Soil in Gilgai Territory**

**Description**

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.
Usage

gilgais

Format

This data frame contains the following columns:

- pH00: pH at depth 0–10 cm.
- pH30: pH at depth 30–40 cm.
- pH60: pH at depth 80–90 cm.
- e00: electrical conductivity in mS/cm (0–10 cm).
- e30: electrical conductivity in mS/cm (30–40 cm).
- e60: electrical conductivity in mS/cm (80–90 cm).
- c00: chloride content in ppm (0–10 cm).
- c30: chloride content in ppm (30–40 cm).
- c60: chloride content in ppm (80–90 cm).

ginv

Generalized Inverse of a Matrix

Description

Calculates the Moore-Penrose generalized inverse of a matrix X.

Usage

ginv(X, tol = sqrt(.Machine$double.eps))

Arguments

- X: Matrix for which the Moore-Penrose inverse is required.
- tol: A relative tolerance to detect zero singular values.

Value

A MP generalized inverse matrix for X.
glm.convert

References

See Also

solve, svd, eigen

Examples

## Not run:
# The function is currently defined as
function(X, tol = sqrt(.Machine$double.eps))
{
## Generalized Inverse of a Matrix
dnx <- dimnames(X)
if(is.null(dnx)) dnx <- vector("list", 2)
s <- svd(X)
nz <- s$df > tol * s$d[1]
structure(
  if(any(nz)) s$v[, nz] %*% (t(s$u[, nz])/s$d[nz]) else X,
  dimnames = dnx[2:1])
}

## End(Not run)

glm.convert

Change a Negative Binomial fit to a GLM fit

Description

This function modifies an output object from glm.nb() to one that looks like the output from glm() with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage

glm.convert(object)

Arguments

object An object of class "negbin", typically the output from glm.nb().

Details

Convenience function needed to effect some low level changes to the structure of the fitted model object.

Value

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.
See Also

 glm.nb, negative.binomial, glm

Examples

 quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)

glm.nb

Fit a Negative Binomial Generalized Linear Model

Description

A modification of the system function glm() to include estimation of the additional parameter, theta, for a Negative Binomial generalized linear model.

Usage

 glm.nb(formula, data, weights, subset, na.action,
 start = NULL, etastart, mustart, 
 control = glm.control(...), method = "glm.fit",
 model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...,
 init.theta, link = log)

Arguments

 formula, data, weights, subset, na.action, start = NULL, etastart, mustart, 
 control = glm.control(...), method = "glm.fit",
 model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...
 init.theta Optional initial value for the theta parameter. If omitted a moment estimator 
after an initial fit using a Poisson GLM is used.
 link The link function. Currently must be one of log, sqrt or identity.

Details

An alternating iteration process is used. For given theta the GLM is fitted using the same process as used by glm(). For fixed theta the parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating theta are controlled by the maxit parameter of glm.control.)

Setting trace > 0 traces the alternating iteration process. Setting trace > 1 traces the glm fit, and setting trace > 2 traces the estimation of theta.

Value

A fitted model object of class negbin inheriting from glm and lm. The object is like the output of glm but contains three additional components, namely theta for the ML estimate of theta, SE.theta for its approximate standard error (using observed rather than expected information), and twologlik for twice the log-likelihood function.
glmmPQL

Fit Generalized Linear Mixed Models via PQL

Description

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

Usage

glmmPQL(fixed, random, family, data, correlation, weights, control, niter = 10, verbose = TRUE, ...)

Arguments

fixed a two-sided linear formula giving fixed-effects part of the model.
random a formula or list of formulae describing the random effects.
family a GLM family.
data an optional data frame used as the first place to find variables in the formulae, weights and if present in ..., subset.
correlation an optional correlation structure.
weights optional case weights as in glm.
control an optional argument to be passed to lme.
niter maximum number of iterations.
verbose logical: print out record of iterations?
... Further arguments for lme.

Details

glmmPQL works by repeated calls to lme, so package nlme will be loaded at first use if necessary.

Value

A object of class "lme": see lmeObject.
References

See Also

`lme`

Examples

```r
library(nlme)  # will be loaded automatically if omitted
summary(glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
              family = binomial, data = bacteria))
```

**hills**

*Record Times in Scottish Hill Races*

Description

The record times in 1984 for 35 Scottish hill races.

Usage

`hills`

Format

The components are:

- `dist` distance in miles (on the map).
- `climb` total height gained during the route, in feet.
- `time` record time in minutes.

Source

[A.C. Atkinson (1988) Transformations unmasked. *Technometrics* 30, 311–318 “corrects” the time for Knock Hill from 78.65 to 18.65. It is unclear if this based on the original records.]

References

**hist.scott**

*Plot a Histogram with Automatic Bin Width Selection*

**Description**

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

**Usage**

```r
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

**Arguments**

- `x` A data vector
- `prob` Should the plot have unit area, so be a density estimate?
- `xlab`, `...` Further arguments to `hist`.

**Value**

For the `nclass.*` functions, the suggested number of classes.

**Side Effects**

Plot a histogram.

huber

*Huber M-estimator of Location with MAD Scale*

**Description**

Finds the Huber M-estimator of location with MAD scale.

**Usage**

huber(y, k = 1.5, tol = 1e-06)

**Arguments**

- **y** vector of data values
- **k** Winsorizes at k standard deviations
- **tol** convergence tolerance

**Value**

list of location and scale parameters

- **mu** location estimate
- **s** MAD scale estimate
Huber Proposal 2 Robust Estimator of Location and/or Scale

Description

Finds the Huber M-estimator for location with scale specified, scale with location specified, or both if neither is specified.

Usage

```r
hubers(y, k = 1.5, mu, s, initmu = median(y), tol = 1e-06)
```

Arguments

- `y`: vector `y` of data values
- `k`: Winsorizes at `k` standard deviations
- `mu`: specified location
- `s`: specified scale
- `initmu`: initial value of `mu`
- `tol`: convergence tolerance

Value

- list of location and scale estimates
- `mu`: location estimate
- `s`: scale estimate

Yields from a Barley Field Trial

Description

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

Usage

`immer`

Format

This data frame contains the following columns:

- **Loc**: The location.
- **Var**: The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").
- **Y1**: Yield in 1931.
- **Y2**: Yield in 1932.

Source

References

Examples

```r
immer.aov <- aov(cbind(Y1,Y2) ~ Loc + Var, data = immer)
summary(immer.aov)

immer.aov <- aov((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
```
Insurance

Numbers of Car Insurance claims

Description

The data given in data frame Insurance consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

Usage

Insurance

Format

This data frame contains the following columns:

District factor: district of residence of policyholder (1 to 4): 4 is major cities.
Group an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.
Age an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.
Holders numbers of policyholders.
Claims numbers of claims

Source

References

Examples

```r
# main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
   data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```
isoMDS  
Kruskal’s Non-metric Multidimensional Scaling

Description
One form of non-metric multidimensional scaling

Usage
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE, 
tol = 1e-3, p = 2)

Shepard(d, x, p = 2)

Arguments
d         distance structure of the form returned by dist, or a full, symmetric matrix.
Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed.
y         An initial configuration. If none is supplied, cmdscale is used to provide the classical solution, unless there are missing or infinite dissimilarities.
k         The desired dimension for the solution, passed to cmdscale.
maxit     The maximum number of iterations.
trace     Logical for tracing optimization. Default TRUE.
tol       convergence tolerance.
p         Power for Minkowski distance in the configuration space.
x         A final configuration.

Details
This chooses a k-dimensional (default k = 2) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.
An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since for the default $p = 2$ the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

Value
Two components:
points     A k-column vector of the fitted configuration.
stress     The final stress achieved (in percent).

Side Effects
If trace is true, the initial stress and the current stress are printed out every 5 iterations.

```

kde2d

Two-Dimensional Kernel Density Estimation

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

Usage

```r
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

Arguments

- **x**: x coordinate of data
- **y**: y coordinate of data
- **h**: vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see `bandwidth.nrd`). A scalar value will be taken to apply to both directions.
- **n**: Number of grid points in each direction. Can be scalar or a length-2 integer vector.
- **lims**: The limits of the rectangle covered by the grid as c(xl, xu, yl, yu).

Value

A list of three components.

- **x**, **y**: The x and y coordinates of the grid points, vectors of length n.

        ylab = "duration", levels = c(0.05, 0.1, 0.2, 0.4))
detach("geyser")
```

### lda

*Linear Discriminant Analysis*

Description

Linear discriminant analysis.

Usage

```r
lda(x, ...)
```

## S3 method for class 'formula'
```r
lda(formula, data, ..., subset, na.action)
```

## Default S3 method:
```r
lda(x, grouping, prior = proportions, tol = 1.0e-4,
    method, CV = FALSE, nu, ...)
```

## S3 method for class 'data.frame'
```r
lda(x, ...)
```

## S3 method for class 'matrix'
```r
lda(x, grouping, ..., subset, na.action)
```
Arguments

- formula: A formula of the form `groups ~ x1 + x2 + ...`. That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
- data: Data frame from which variables specified in `formula` are preferentially to be taken.
- x: (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
- grouping: (required if no formula principal argument is given.) a factor specifying the class for each observation.
- prior: the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.
- tol: A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than `tol^2`.
- subset: An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
- na.action: A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is `na.omit`, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
- method: "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use `cov.mve`, or "t" for robust estimates based on a t distribution.
- CV: If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
- nu: degrees of freedom for method = "t".
- ... arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the prior will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

Value

If `CV = TRUE` the return value is a list with components class, the MAP classification (a factor), and posterior, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

- prior: the prior probabilities used.
means the group means.
scaling a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.
svd the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.

N The number of observations used.
call The (matched) function call.

Note
This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but subset= and na.action=, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using update() in the usual way.

ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks, 
    xlim = range(breaks), ymax = 0, width,
    type = c("histogram", "density", "both"),
    sep = (type != "density"),
    col = 5, xlab = deparse(substitute(data)), bty = "n", ...)

Arguments

data vector of data. Missing values (NAs) are allowed and omitted.
g factor or vector giving groups, of the same length as data.
nbins Suggested number of bins to cover the whole range of the data.
h The bin width (takes precedence over nbins).
x0 Shift for the bins - the breaks are at x0 + h * (... -1, 0, 1, ...)
bbreaks The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
xlim The limits for the x-axis.
ymax The upper limit for the y-axis.
width Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately.
type Type of plot.
sep Whether there is a separate plot for each group, or one combined plot.
col The colour number for the bar fill.
xlab label for the plot x-axis. By default, this will be the name of data.
bty The box type for the plot - defaults to none.
... additional arguments to polygon.

Side Effects

Histogram and/or density plots are plotted on the current device.

plot.lda.
Description

A data frame of data from 33 leukaemia patients.

Usage

leuk

Format

A data frame with columns:

- wbc  white blood count.
- ag   a test result, "present" or "absent".
- time survival time in weeks.

Details

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient’s white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

**lm.gls**

*Fit Linear Models by Generalized Least Squares*

**Description**

Fit linear models by Generalized Least Squares

**Usage**

```r
lm.gls(formula, data, W, subset, na.action, inverse = FALSE, 
method = "qr", model = FALSE, x = FALSE, y = FALSE, 
contrasts = NULL, ...)
```

**Arguments**

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- `data`: an optional data frame in which to interpret the variables occurring in `formula`.
- `W`: a weight matrix.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `inverse`: logical: if true `W` specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
- `method`: method to be used by `lm.fit`.
- `model`: should the model frame be returned?
- `x`: should the design matrix be returned?
- `y`: should the response be returned?
- `contrasts`: a list of contrasts to be used for some or all of
- `...`: additional arguments to `lm.fit`.

**Details**

The problem is transformed to uncorrelated form and passed to `lm.fit`.

**Value**

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

**See Also**

`gls`, `lm`, `lm.ridge`
Ridge Regression

Description

Fit a linear model by ridge regression.

Usage

```r
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
         x = FALSE, y = FALSE, contrasts = NULL, ...)
```

Arguments

- `formula`: a formula expression as for regression models, of the form `response ~ predictors`. See the documentation of `formula` for other details.
- `offset`: terms are allowed.
- `data`: an optional data frame in which to interpret the variables occurring in `formula`.
- `subset`: expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
- `na.action`: a function to filter missing data.
- `lambda`: A scalar or vector of ridge constants.
- `model`: should the model frame be returned? Not implemented.
- `x`: should the design matrix be returned? Not implemented.
- `y`: should the response be returned? Not implemented.
- `contrasts`: a list of contrasts to be used for some or all of factor terms in the formula. See the `contrasts.arg` of `model.matrix.default`.
- `...`: additional arguments to `lm.fit`.

Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

Value

A list with components

- `coef`: matrix of coefficients, one row for each value of `lambda`. Note that these are not on the original scale and are for use by the `coef` method.
- `scales`: scalings used on the X matrix.
- `Inter`: was intercept included?
- `lambda`: vector of lambda values
- `ym`: mean of y
- `xm`: column means of x matrix
- `GCV`: vector of GCV values
- `kHKB`: HKB estimate of the ridge constant.
- `kLW`: L-W estimate of the ridge constant.

loglm

Fit Log-Linear Models by Iterative Proportional Scaling

Description

This function provides a front-end to the standard function, loglin, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as glm.

Usage

loglm(formula, data, subset, na.action, …)

Arguments

formula A linear model formula specifying the log-linear model.

If the left-hand side is empty, the data argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the dimnames attribute of the frequency array, or may be the positive integers: 1, 2, 3, … used as alternative names for the 1st, 2nd, 3rd, … dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the data argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a . to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.

data Numeric array or data frame. In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way.

This argument may be the result of a call to xtabs.

subset Specifies a subset of the rows in the data frame to be used. The default is to take all rows.

na.action Specifies a method for handling missing observations. The default is to fail if missing values are present.

… May supply other arguments to the function loglm1.
**Details**

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

**Value**

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

**Warning**

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

`logtrans` Estimate log Transformation Parameter

**Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form $\log(y + \alpha) \sim x_1 + x_2 + \ldots$. 

**Usage**

```r
logtrans(object, ...) 
```

## Default S3 method:

```r
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y), plotit = TRUE, interp =, xlab = "alpha", ylab = "log Likelihood") 
```

## S3 method for class 'formula'

```r
logtrans(object, data, ...) 
```

## S3 method for class 'lm'

```r
logtrans(object, ...) 
```

**Arguments**

- `object` Fitted linear model object, or formula defining the untransformed model that is $y \sim x_1 + x_2 + \ldots$. The function is generic.
- `...` If `object` is a formula, this argument may specify a data frame as for `lm`. 

```r
fm <- loglm(~ 1 + 2 + 3 + 4, minn38a) # numerals as names.
deviance(fm)
## [1] 3711.9
fm1 <- update(fm, .~.^2)
fm2 <- update(fm, .~.^3, print = TRUE)
## 5 iterations: deviation 0.075
anova(fm, fm1, fm2)

# Case 1. An array generated with xtabs.

loglm(~ Type + Origin, xtabs(~ Type + Origin, Cars93))

# Case 2. Frequencies given as a vector in a data frame

names(quine)
## [1] "Eth" "Sex" "Age" "Lrn" "Days"
fm <- loglm(Days ~ .^2, quine)

gm <- glm(Days ~ .^2, poisson, quine) # check glm.
c(deviance(fm), deviance(gm)) # deviances agree
## [1] 1368.7 1368.7
c(fm$df, gm$df) # resid df do not!
c(fm$df, gm$df.residual) # resid df do not!
## [1] 127 128
# The loglm residual degrees of freedom is wrong because of
# a non-detectable redundancy in the model matrix.
```
alpha  Set of values for the transformation parameter, alpha.
plotit Should plotting be done?
interp Should the marginal log-likelihood be interpolated with a spline approximation? (Default is TRUE if plotting is to be done and the number of real points is less than 100.)
xlab  as for plot.
ylab  as for plot.
data  optional data argument for lm fit.

Value
List with components x (for alpha) and y (for the marginal log-likelihood values).

Side Effects
A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

lqs Resistant Regression

Description
Fit a regression to the good points in the dataset, thereby achieving a regression estimator with a high breakdown point. lmsreg and ltsreg are compatibility wrappers.

Usage
lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ..., 
    method = c("lts", "lqs", "lms", "S", "model.frame"), 
    subset, na.action, model = TRUE, 
    x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
quantile, control = lqs.control(...), k0 = 1.548, seed, ...)
lmsreg(...)ltsreg(...)

**Arguments**

- **formula**: a formula of the form \(y \sim x_1 + x_2 + \ldots\)
- **data**: data frame from which variables specified in `formula` are preferentially to be taken.
- **subset**: an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)
- **na.action**: function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include `na.omit` and `na.exclude`, which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.)
- **model, x.ret, y.ret**: logical. If `TRUE` the model frame, the model matrix and the response are returned, respectively.
- **contrasts**: an optional list. See the `contrasts.arg` of `model.matrix.default`.
- **x**: a matrix or data frame containing the explanatory variables.
- **y**: the response: a vector of length the number of rows of `x`.
- **intercept**: should the model include an intercept?
- **method**: the method to be used. `model.frame` returns the model frame: for the others see the Details section. Using `lmsreg` or `ltsreg` forces "lms" and "lts" respectively.
- **quantile**: the quantile to be used: see Details. This is over-ridden if `method = "lms"`.
- **control**: additional control items: see Details.
- **k0**: the cutoff / tuning constant used for \(\chi()\) and \(\psi()\) functions when `method = "S"`, currently corresponding to Tukey’s ‘biweight’.
- **seed**: the seed to be used for random sampling: see `.Random.seed`. The current value of `.Random.seed` will be preserved if it is set.
- **...**: arguments to be passed to `lqs.default` or `lqs.control`, see control above and Details.

**Details**

Suppose there are \(n\) data points and \(p\) regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are `floor((n+p+1)/2)` and `floor((n+1)/2)` respectively. For "lts" the default is `floor(n/2) + floor((p+1)/2)`.

The "S" estimation method solves for the scale \(s\) such that the average of a function chi of the residuals divided by \(s\) is equal to a given constant.

The `control` argument is a list with components

- **psamp**: the size of each sample. Defaults to \(p\).
nsamp: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is min(5*p, 3000), taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

adjust: should the intercept be optimized for each sample? Defaults to TRUE.

Value
An object of class "lqs". This is a list with components

crit the value of the criterion for the best solution found, in the case of method == "S" before IWLS refinement.
sing character. A message about the number of samples which resulted in singular fits.
coefficients of the fitted linear model
bestone the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
fitted.values the fitted values.
residuals the residuals.
scale estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for method == "S") is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

Note
There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate \( n^{-1/3} \)) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of \((\text{floor}((n-p)/2) + 1)/n\) attained if \(\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)\). The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if \( n \) is large and \( p \) small.

Opinions differ over the choice of psamp. Rousseeuw and Hubert (1997) only consider \( p \); Marazzi (1993) recommends \( p+1 \) and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

Multiple Correspondence Analysis

Description

Computes a multiple correspondence analysis of a set of factors.

Usage

mca(df, nf = 2, abbrev = FALSE)

Arguments

df  A data frame containing only factors
nf  The number of dimensions for the MCA. Rarely 3 might be useful.
abbrev  Should the vertex names be abbreviated? By default these are of the form 'factor.level' but if abbrev = TRUE they are just 'level' which will suffice if the factors have distinct levels.

Value

An object of class "mca", with components

rs  The coordinates of the rows, in nf dimensions.
cs  The coordinates of the column vertices, one for each level of each factor.
fs  Weights for each row, used to interpolate additional factors in predict.mca.
p  The number of factors
d  The singular values for the nf dimensions.
call  The matched call.

Michelson’s Speed of Light Data

Description
Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

Usage
michelson

Format
The data frame contains the following components:

- **Expt** The experiment number, from 1 to 5.
- **Run** The run number within each experiment.
- **Speed** Speed-of-light measurement.

References

minn38  

Minnesota High School Graduates of 1938

Description
The Minnesota high school graduates of 1938 were classified according to four factors, described below. The minn38 data frame has 168 rows and 5 columns.

Usage
minn38

Format
This data frame contains the following columns:

- **hs** high school rank: "L", "M" and "U" for lower, middle and upper third.
- **phs** post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").
- **fol** father’s occupational level, (seven levels, "F1", "F2", . . . , "F7").
- **sex** sex: factor with levels "F" or "M".
- **f** frequency.
**Source**

---

**motors**

**Accelerated Life Testing of Motorettes**

**Description**

The motors data frame has 40 rows and 3 columns. It describes an accelerated life test at each of four temperatures of 10 motorettes, and has rather discrete times.

**Usage**

`motors`

**Format**

This data frame contains the following columns:

- `temp` the temperature (degrees C) of the test.
- `time` the time in hours to failure or censoring at 8064 hours (= 336 days).
- `cens` an indicator variable for death.

**Source**

**References**

**Examples**

```r
library(survival)
plot(survfit(Surv(time, cens) ~ factor(temp), motors), conf.int = FALSE)
# fit Weibull model
motor.wei <- survreg(Surv(time, cens) ~ temp, motors)
summary(motor.wei)
# and predict at 130C
unlist(predict(motor.wei, data.frame(temp=130), se.fit = TRUE))

motor.cox <- coxph(Surv(time, cens) ~ temp, motors)
summary(motor.cox)
# predict at temperature 200
```
The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

**Usage**

```
muscle
```

**Format**

This data frame contains the following columns:

- **Strip** which heart muscle strip was used?
- **Conc** concentration of calcium chloride solution, in multiples of 2.2 mM.
- **Length** the change in length (shortening) of the strip, (allegedly) in mm.

**Source**

**References**

**Examples**

```
A <- model.matrix(~ Strip - 1, data=muscle)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho^Conc),
                       data = muscle, start = c(rho=0.1), algorithm="plinear")
(B <- coef(rats.nls1))

st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[Strip] + beta*rho^Conc,
                       data = muscle, start = st))

Muscle <- with(muscle, {
  Muscle <- expand.grid(Conc = sort(unique(Conc)), Strip = levels(Strip))
  Muscle$Yhat <- predict(rats.nls2, Muscle)
  Muscle <- cbind(Muscle, logLength = rep(as.numeric(NA), 126))
})
```
ind <- match(paste(Strip, Conc),
    paste(Muscle$Strip, Muscle$Conc))
Muscle$logLength[ind] <- log(Length)
Muscle})
lattice::xyplot(Yhat ~ Conc | Strip, Muscle, as.table = TRUE,
    ylim = range(c(Muscle$Yhat, Muscle$logLength), na.rm = TRUE),
    subscripts = TRUE, xlab = "Calcium Chloride concentration (mM)",
    ylab = "log(Length in mm)", panel =
    function(x, y, subscripts, ...) {
        panel.xyplot(x, Muscle$logLength[subscripts], ...)
        llines(spline(x, y))
    })

**mvnorm**  
*Simulate from a Multivariate Normal Distribution*

**Description**

Produces one or more samples from the specified multivariate normal distribution.

**Usage**

`mvnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)`

**Arguments**

- `n` the number of samples required.
- `mu` a vector giving the means of the variables.
- `Sigma` a positive-definite symmetric matrix specifying the covariance matrix of the variables.
- `tol` tolerance (relative to largest variance) for numerical lack of positive-definiteness in `Sigma`.
- `empirical` logical. If true, `mu` and `Sigma` specify the empirical not population mean and covariance matrix.
- `EISPACK` logical: values other than FALSE are an error.

**Details**

The matrix decomposition is done via eigen; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

**Value**

If `n = 1` a vector of the same length as `mu`, otherwise an `n` by `length(mu)` matrix with one sample in each row.

**Side Effects**

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.
negative.binomial

Family function for Negative Binomial GLMs

Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known theta parameter, using glm().

Usage

negative.binomial(theta = stop("'theta' must be specified"), link = "log")

Arguments

theta

The known value of the additional parameter, theta.

link

The link function, as a character string, name or one-element character vector specifying one of log, sqrt or identity, or an object of class "link-glm".

Value

An object of class "family", a list of functions and expressions needed by glm() to fit a Negative Binomial generalized linear model.

References

See Also

glm.nb, anova.negbin, summary.negbin

Examples

# Fitting a Negative Binomial model to the quine data
# with theta = 2 assumed known.
#
glm(Days ~ .^4, family = negative.binomial(2), data = quine)
newcomb

Description
A numeric vector giving the ‘Third Series’ of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24 give the time in millionths of a second for light to traverse a known distance. The ‘true’ value is now considered to be 33.02.

Usage
newcomb

Source

nlschools

Description
Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

Usage
nlschools

Format
This data frame contains 2287 rows and the following columns:

- lang language test score.
- IQ verbal IQ.
- class class ID.
- GS class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).
- SES social-economic status of pupil’s family.
- COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

Source
References

Examples

```r
nl1 <- within(nlschools, {
Iqave <- tapply(IQ, class, mean)[as.character(class)]
IQ <- IQ - IQave
})
cen <- c("IQ", "Iqave", "SES")
nl1[cen] <- scale(nl1[cen], center = TRUE, scale = FALSE)

nl.lme <- nlme::lme(lang ~ IQ*COMB + IQave + SES, 
                    random = ~ IQ | class, data = nl1)
summary(nl.lme)
```

npk

Classical N, P, K Factorial Experiment

Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

npk

Format

The npk data frame has 24 rows and 5 columns:

- block which block (label 1 to 6).
- N indicator (0/1) for the application of nitrogen.
- P indicator (0/1) for the application of phosphate.
- K indicator (0/1) for the application of potassium.
- yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

Note

This dataset is also contained in R 3.0.2 and later.

Source

References

Examples

```r
options(contrasts = c("contr.sum", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
npk.aov
summary(npk.aov)
alias(npk.aov)
coef(npk.aov)
options(contrasts = c("contr.treatment", "contr.poly"))
npk.aov1 <- aov(yield ~ block + N + K, data = npk)
summary.lm(npk.aov1)
se.contrast(npk.aov1, list(N="0", N="1"), data = npk)
model.tables(npk.aov1, type = "means", se = TRUE)
```

**npr1**

*US Naval Petroleum Reserve No. 1 data*

**Description**

Data on the locations, porosity and permeability (a measure of oil flow) on 104 oil wells in the US Naval Petroleum Reserve No. 1 in California.

**Usage**

`npr1`

**Format**

This data frame contains the following columns:

- **x** x coordinates, in miles (origin unspecified).
- **y** y coordinates, in miles.
- **perm** permeability in milli-Darcies.
- **por** porosity (%).

**Source**

**References**

Null

Null Spaces of Matrices

Description

Given a matrix, \( M \), find a matrix \( N \) giving a basis for the (left) null space. That is \( \mathrm{crossprod}(N, M) = t(N) \times M \) is an all-zero matrix and \( N \) has the maximum number of linearly independent columns.

Usage

\[ \text{Null}(M) \]

Arguments

\( M \)

Input matrix. A vector is coerced to a 1-column matrix.

Details

For a basis for the (right) null space \( \{ x : Mx = 0 \} \), use \( \text{Null}(t(M)) \).

Value

The matrix \( N \) with the basis for the (left) null space, or a matrix with zero columns if the matrix \( M \) is square and of maximal rank.

References

See Also

\( \text{qr}, \text{qr.Q} \).

Examples

# The function is currently defined as
\[
function(M) 
\{
  \text{tmp} <- \text{qr}(M)
  \text{set} <- \text{if}(\text{tmp}\$rank == 0L) \text{seq_len(ncol(M))} \text{else} -\text{seq_len(tmp}\$rank)
  \text{qr.Q}(\text{tmp}, \text{complete} = \text{TRUE})[, \text{set}, \text{drop} = \text{FALSE}]
\}
Data from an Oats Field Trial

Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

Usage

oats

Format

This data frame contains the following columns:

B Blocks, levels I, II, III, IV, V and VI.
V Varieties, 3 levels.
N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.
Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

model.tables(oats.aov2, type = "means", se = TRUE)
Description

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

Usage

OME

Format

The OME data frame has 1129 rows and 7 columns:

ID  Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.
OME  "low" or "high" or "N/A" (at ages other than 30 and 60 months).
Age  Age of the subject (months).
Loud  Loudness of stimulus, in decibels.
Noise  Whether the signal in the stimulus was "coherent" or "incoherent".
Correct  Number of correct responses from Trials trials.
Trials  Number of trials performed.

Background

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term ‘binaural hearing’ is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

## End(Not run)

## Description

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

## Usage

painters
pairs.lda

Format

The row names of the data frame are the painters. The components are:

Composition Composition score.
Drawing Drawing score.
Colour Colour score.
Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows: "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

pairs.lda Produce Pairwise Scatterplots from an 'lda' Fit

Description

Pairwise scatterplot of the data on the linear discriminants.

Usage

## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda,
dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))

Arguments

x Object of class "lda".
labels vector of character strings for labelling the variables.
panel panel function to plot the data in each panel.
dimen The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.
abbrev whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
... additional arguments for pairs.default.
cex graphics parameter cex for labels on plots.
type type of plot. The default is in the style of pairs.default; the style "trellis" uses the Trellis function splom.
Details

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

Parallel Coordinates Plot

Description

Parallel coordinates plot

Usage

```r
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

Arguments

- `x` a matrix or data frame who columns represent variables. Missing values are allowed.
- `col` A vector of colours, recycled as necessary for each observation.
- `lty` A vector of line types, recycled as necessary for each observation.
- `var.label` If `TRUE`, each variable’s axis is labelled with maximum and minimum values.
- `...` Further graphics parameters which are passed to `matplot`.

Side Effects

a parallel coordinates plots is drawn.

Author(s)

B. D. Ripley. Enhancements based on ideas and code by Fabian Scheipl.

References

Examples

```r
parcoord(state.x77[, c(7, 4, 6, 2, 5, 3)])
ir <- rbind(iris3[,1], iris3[,2], iris3[,3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```
**Description**

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

**Usage**

```
petrol
```

**Format**

The variables are as follows:

- **No** crude oil sample identification label. (Factor.)
- **SG** specific gravity, degrees API. (Constant within sample.)
- **VP** vapour pressure in pounds per square inch. (Constant within sample.)
- **V10** volatility of crude; ASTM 10% point. (Constant within sample.)
- **EP** desired volatility of gasoline. (The end point. Varies within sample.)
- **Y** yield as a percentage of crude.

**Source**

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.

**References**

**Examples**

```
library(nlme)
Petrol <- petrol
Petrol[, 2:5] <- scale(as.matrix(Petrol[, 2:5]), scale = FALSE)
pet3.lme <- lme(Y ~ SG + VP + V10 + EP,
                random = ~ 1 | No, data = Petrol)
pet3.lme <- update(pet3.lme, method = "ML")
pet4.lme <- update(pet3.lme, fixed = Y ~ V10 + EP)
anova(pet4.lme, pet3.lme)
```
Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage

Pima.tr  
Pima.tr2  
Pima.te

Format

These data frames contain the following columns:

npreg  number of pregnancies.
glu  plasma glucose concentration in an oral glucose tolerance test.
bp  diastolic blood pressure (mm Hg).
skin  triceps skin fold thickness (mm).
bmi  body mass index (weight in kg/(height in m)²).
ped  diabetes pedigree function.
age  age in years.
type  Yes or No, for diabetic according to WHO criteria.

Details

The training set Pima.tr contains a randomly selected set of 200 subjects, and Pima.te contains the remaining 332 subjects. Pima.tr2 contains Pima.tr plus 100 subjects with missing values in the explanatory variables.

Source

plot.lda

Plot Method for Class 'lda'

Description

Plots a set of data on one, two or more linear discriminants.

Usage

## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
     abbrev = FALSE, xlab = "LD1", ylab = "LD2")

Arguments

x  An object of class "lda".
panel the panel function used to plot the data.
... additional arguments to pairs, ldahist or eqscplot.
cex graphics parameter cex for labels on plots.
dimen The number of linear discriminants to be used for the plot; if this exceeds the
number determined by x the smaller value is used.
abbrev whether the group labels are abbreviated on the plots. If abbrev > 0 this gives
minlength in the call to abbreviate.
xlab label for the x axis
ylab label for the y axis

Details

This function is a method for the generic function plot() for class "lda". It can be invoked
by calling plot(x) for an object x of the appropriate class, or directly by calling plot.lda(x)
regardless of the class of the object.

The behaviour is determined by the value of dimen. For dimen > 2, a pairs plot is used. For
dimen = 2, an equiscaled scatter plot is drawn. For dimen = 1, a set of histograms or density plots
are drawn. Use argument type to match "histogram" or "density" or "both".

plot.mca

Plot Method for Objects of Class 'mca'

Description
Plot a multiple correspondence analysis.

Usage
## S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)

Arguments
x
An object of class "mca".

rows
Should the coordinates for the rows be plotted, or just the vertices for the levels?

col, cex
The colours and cex to be used for the row points and level vertices respectively.

...
Additional parameters to plot.

plot.profile

Plotting Functions for 'profile' Objects

Description
plot and pairs methods for objects of class "profile".

Usage
## S3 method for class 'profile'
plot(x, ...)

## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)

Arguments
x
an object inheriting from class "profile".

colours
Colours to be used for the mean curves conditional on x and y respectively.

...
arguments passed to or from other methods.
Details

This is the main plot method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters x and y, two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of y|x and x|y, and the contours would be exactly elliptical.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

See Also

`profile.glm`, `profile.nls`.

Examples

```r
## see ?profile.glm for an example using glm fits.
## a version of example(profile.nls) from R >= 2.8.0
fm1 <- nls(demand ~ SSasympOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fm1, alpha = 0.1)
MASS:::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated
## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

polr

Ordered Logistic or Probit Regression

Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is proportional odds logistic regression, after which the function is named.

Usage

```r
polr(formula, data, weights, start, ..., subset, na.action,
    contrasts = NULL, Hess = FALSE, model = TRUE,
    method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```
Arguments

formula  
a formula expression as for regression models, of the form  
response ~ predictors. The response should be a factor (preferably  
an ordered factor), which will be interpreted as an ordinal response, with levels  
ordered as in the factor. The model must have an intercept: attempts to remove  
one will lead to a warning and be ignored. An offset may be used. See the  
documentation of formula for other details.

data  
an optional data frame in which to interpret the variables occurring in formula.

weights  
optional case weights in fitting. Default to 1.

start  
initial values for the parameters. This is in the format c(coefficients, zeta):  
see the Values section.

...  
additional arguments to be passed to optim, most often a control argument.

subset  
expression saying which subset of the rows of the data should be used in the fit.  
All observations are included by default.

na.action  
a function to filter missing data.

contrasts  
a list of contrasts to be used for some or all of the factors appearing as variables  
in the model formula.

Hess  
logical for whether the Hessian (the observed information matrix) should be  
returned. Use this if you intend to call summary or vcov on the fit.

model  
logical for whether the model matrix should be returned.

method  
logistic or probit or (complementary) log-log or cauchit (corresponding to a  
Cauchy latent variable).

Details

This model is what Agresti (2002) calls a cumulative link model. The basic interpretation is as a  
coarsened version of a latent variable $Y_i$ which has a logistic or normal or extreme-value or Cauchy  
distribution with scale parameter one and a linear model for the mean. The ordered factor which is  
observed is which bin $Y_i$ falls into with breakpoints  
\[
\zeta_0 = -\infty < \zeta_1 < \cdots < \zeta_K = \infty
\]

This leads to the model  
\[
\text{logit} P(Y \leq k | x) = \zeta_k - \eta
\]

with logit replaced by probit for a normal latent variable, and $\eta$ being the linear predictor, a linear  
function of the explanatory variables (with no intercept). Note that it is quite common for other  
software to use the opposite sign for $\eta$ (and hence the coefficients beta).

In the logistic case, the left-hand side of the last display is the log odds of category $k$ or less, and  
since these are log odds which differ only by a constant for different $k$, the odds are proportional.  
Hence the term proportional odds logistic regression.

The log-log and complementary log-log links are the increasing functions  
$F^{-1}(p) = -\log(-\log(p))$ and $F^{-1}(p) = \log(-\log(1 - p))$; some call the first the ‘negative log-log’ link.  
These correspond to a latent variable with the extreme-value distribution for the maximum and  
minimum respectively.

A proportional hazards model for grouped survival times can be obtained by using the complementary  
log-log link with grouping ordered by increasing times.

predict, summary, vcov, anova, model.frame and an extractAIC method for use with stepAIC  
(and step). There are also profile and confint methods.
Value

A object of class "polr". This has components

- coefficients: the coefficients of the linear predictor, which has no intercept.
- zeta: the intercepts for the class boundaries.
- deviance: the residual deviance.
- fitted.values: a matrix, with a column for each level of the response.
- lev: the names of the response levels.
- terms: the terms structure describing the model.
- df.residual: the number of residual degrees of freedom, calculated using the weights.
- edf: the (effective) number of degrees of freedom used by the model
- n, nobs: the (effective) number of observations, calculated using the weights. (nobs is for use by stepAIC.
- call: the matched call.
- method: the matched method used.
- convergence: the convergence code returned by optim.
- niter: the number of function and gradient evaluations used by optim.
- lp: the linear predictor (including any offset).
- Hessian: (if Hess is true). Note that this is a numerical approximation derived from the optimization process.
- model: (if model is true).

Note

The vcov method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, method = "cloglog" confusingly gave the log-log link, implicitly assuming the first response level was the ‘best’.

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
house.plr <- polr(Sat ~ Infl + Type + Cont, weights = Freq, data = housing)
house.plr
summary(house.plr, digits = 3)
## slightly worse fit from
summary(update(house.plr, method = "probit", Hess = TRUE), digits = 3)
## although it is not really appropriate, can fit
summary(update(house.plr, method = "loglog", Hess = TRUE), digits = 3)
```
summary(update(house.plr, method = "cloglog", Hess = TRUE), digits = 3)
predict(house.plr, housing, type = "p")
addterm(house.plr, ~.^2, test = "Chisq")
house.plr2 <- stepAIC(house.plr, ~.^2)
house.plr2$anova
anova(house.plr, house.plr2)

house.plr <- update(house.plr, Hess=TRUE)
pr <- profile(house.plr)
confint(pr)
plot(pr)
pairs(pr)

predict.glmmPQL

Predict Method for glmmPQL Fits

Description

Obtains predictions from a fitted generalized linear model with random effects.

Usage

## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
         level, na.action = na.pass, ...)

Arguments

object a fitted object of class inheriting from "glmmPQL".
newdata optionally, a data frame in which to look for variables with which to predict.
type the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
level an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
na.action function determining what should be done with missing values in newdata. The default is to predict NA.
... further arguments passed to or from other methods.

Value

If level is a single integer, a vector otherwise a data frame.

See Also

glmmPQL, predict.lme.
Examples

```r
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
               family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

predict.lda

Classify Multivariate Observations by Linear Discrimination

Description

Classify multivariate observations in conjunction with lda, and also project data onto the linear discriminants.

Usage

```r
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
         method = c("plug-in", "predictive", "debiased"), ...)
```

Arguments

- `object`: object of class "lda"
- `newdata`: data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the lda object.
- `prior`: The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to lda.
- `dimen`: the dimension of the space to be used. If this is less than \( \min(p, n_g - 1) \), only the first `dimen` discriminant components are used (except for `method="predictive"`), and only those dimensions are returned in `x`.
- `method`: This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
- `...`: arguments based from or to other methods

Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning NA if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.
predict.lqs

**Value**

a list with components

- **class**: The MAP classification (a factor)
- **posterior**: posterior probabilities for the classes
- **x**: the scores of test cases on up to `dimen` discriminant variables

**References**

**See Also**

`lda`, `qda`, `predict.qda`

**Examples**

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[tr,,1], iris3[tr,,2], iris3[tr,,3])
test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- lda(train, cl)
predict(z, test)$class
```

---

**predict.lqs**  
*Predict from an lqs Fit*

**Description**

Predict from an resistant regression fitted by `lqs`.

**Usage**

```r
## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

**Arguments**

- **object**: object inheriting from class "lqs"
- **newdata**: matrix or data frame of cases to be predicted or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the `lqs` object.
- **na.action**: function determining what should be done with missing values in `newdata`. The default is to predict `NA`.
- **...**: arguments to be passed from or to other methods.
predict.mca

Details

This function is a method for the generic function predict() for class lqs. It can be invoked by calling predict(x) for an object x of the appropriate class, or directly by calling predict.lqs(x) regardless of the class of the object.

Missing values in newdata are handled by returning NA if the linear fit cannot be evaluated. If newdata is omitted and the na.action of the fit omitted cases, these will be omitted on the prediction.

Value

A vector of predictions.

lqs

Examples

set.seed(123)
fm <- lqs(stack.loss ~ ., data = stackloss, method = "S", nsamp = "exact")
predict(fm, stackloss)

predict.mca

Description

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

Usage

## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)  

Arguments

object

An object of class "mca", usually the result of a call to mca.

newdata

A data frame containing either additional rows of the factors used to fit object or additional factors for the cases used in the original fit.

type

Are predictions required for further rows or for new factors?

...  

Additional arguments from predict: unused.

Value

If type = "row", the coordinates for the additional rows.

If type = "factor", the coordinates of the column vertices for the levels of the new factors.

**predict.qda**

Classify from Quadratic Discriminant Analysis

**Description**

Classify multivariate observations in conjunction with *qda*

**Usage**

```r
## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
    method = c("plug-in", "predictive", "debiased", "looCV"), ...)
```

**Arguments**

- `object` : object of class "qda"
- `newdata` : data frame of cases to be classified or, if `object` has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If `newdata` is missing, an attempt will be made to retrieve the data used to fit the *qda* object.
- `prior` : The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to *qda*.
- `method` : This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned.
- `...` : arguments based from or to other methods

**Details**

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.
Value

A list with components

- `class`: The MAP classification (a factor)
- `posterior`: posterior probabilities for the classes

References

Examples

```r
tr <- sample(1:50, 25)
train <- rbind(iris3[,1,], iris3[,2,], iris3[,3,])
test <- rbind(iris3[-tr,1,], iris3[-tr,2,], iris3[-tr,3,])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
qz <- qda(train, cl)
predict(qz, test)$class
```

profile.glm

Method for Profiling glm Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

```r
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
        del = zmax/5, trace = FALSE, ...)
```

Arguments

- `fitted`: the original fitted model object.
- `which`: the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
- `alpha`: highest significance level allowed for the profile t-statistics.
- `maxsteps`: maximum number of points to be used for profiling each parameter.
- `del`: suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
- `trace`: logical: should the progress of profiling be reported?
- `...`: further arguments passed to or from other methods.
Details

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

- par.vals: a matrix of parameter values for each fitted model.
- tau: the profile t-statistics.

Author(s)

glm, profile, plot.profile

Examples

```r
options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

qda

Quadratic Discriminant Analysis

Description

Quadratic discriminant analysis.

Usage

```r
qda(x, ...)
```

## S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
     method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
qda(x, ...)
```
### S3 method for class 'matrix'

`qda(x, grouping, ..., subset, na.action)`

**Arguments**

- **formula**
  A formula of the form `groups ~ x1 + x2 + ...` That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.

- **data**
  Data frame from which variables specified in formula are preferentially to be taken.

- **x**
  (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.

- **grouping**
  (required if no formula principal argument is given.) a factor specifying the class for each observation.

- **prior**
  the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.

- **subset**
  An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)

- **na.action**
  A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is na.omit, which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)

- **method**
  "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use cov.mve, or "t" for robust estimates based on a t distribution.

- **CV**
  If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.

- **nu**
  degrees of freedom for method = "t".

- **...**
  arguments passed to or from other methods.

**Details**

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

**Value**

an object of class "qda" containing the following components:

- **prior**
  the prior probabilities used.

- **means**
  the group means.

- **scaling**
  for each group i, scaling[,i] is an array which transforms observations so that within-groups covariance matrix is spherical.

- **ldet**
  a vector of half log determinants of the dispersion matrix.

- **lev**
  the levels of the grouping factor.

- **terms**
  (if formula is a formula) an object of mode expression and class term summarizing the formula.
call the (matched) function call.

unless CV=TRUE, when the return value is a list with components:

class The MAP classification (a factor)
posterior posterior probabilities for the classes

z <- qda(train, cl)
predict(z,test)$class

quine Absenteeism from School in Rural New South Wales

Description
The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

Usage
quine

Format
This data frame contains the following columns:

Eth  ethnic background: Aboriginal or Not, ("A" or "N").
Sex  sex: factor with levels ("F" or "M").
Age  age group: Primary ("F0")., or forms "F1", "F2" or "F3".
Lrn  learner status: factor with levels Average or Slow learner, ("AL" or "SL").
Days days absent from school in the year.
