

# Package ‘zoo’

January 2, 2012

**Version** 1.7-6

**Date** 2011-11-02

**Title** S3 Infrastructure for Regular and Irregular Time Series (Z’s ordered observations)

**Description** An S3 class with methods for totally ordered indexed observations. It is particularly aimed at irregular time series of numeric vectors/matrices and factors. zoo’s key design goals are independence of a particular index/date/time class and consistency with ts and base R by providing methods to extend standard generics.

**Depends** R (>= 2.10.0), stats

**Suggests**

coda, chron, DAAG, fts, its, lattice, mondate, strucchange,timeDate, timeSeries, tis, tseries, xts

**Imports** stats, utils, graphics, grDevices, lattice (>= 0.18-1)

**License** GPL-2

**URL** <http://zoo.R-Forge.R-project.org/>

**Author** Achim Zeileis [aut, cre],Gabor Grothendieck [aut],Jeffrey A. Ryan [aut],Felix Andrews [ctb]

**Maintainer** Achim Zeileis <Achim.Zeileis@R-project.org>

**Repository** CRAN

**Date/Publication** 2011-11-02 18:40:09

aggregate.zoo	<i>Compute Summary Statistics of zoo Objects</i>
---------------	--

---

## Description

Splits a "zoo" object into subsets along a coarser index grid, computes summary statistics for each, and returns the reduced "zoo" object.

## Usage

```
## S3 method for class 'zoo'
aggregate(x, by, FUN = sum, ..., regular = NULL, frequency = NULL)
```

## Arguments

x	an object of class "zoo".
by	index vector of the same length as index(x) which defines aggregation groups and the new index to be associated with each group. If by is a function, then it is applied to index(x) to obtain the aggregation groups.
FUN	a scalar function to compute the summary statistics which can be applied to all subsets.
...	further arguments passed to FUN.

regular	logical. Should the aggregated series be coerced to class "zooreg" (if the series is regular)? The default is FALSE for "zoo" series and TRUE for "zooreg" series.
frequency	numeric indicating the frequency of the aggregated series (if a "zooreg" series should be returned. The default is to determine the frequency from the data if regular is TRUE. If frequency is specified, it sets regular to TRUE. See examples for illustration.

**Value**

An object of class "zoo" or "zooreg".

**Note**

The xts package functions endpoints, period.apply to.period, to.weekly, to.monthly, etc., can also directly input and output certain zoo objects and so can be used for aggregation tasks in some cases as well.

**See Also**

[zoo](#)

**Examples**

```
## averaging over values in a month:
# x.date is jan 1,3,5,7; feb 9,11,13; mar 15,17,19
x.date <- as.Date(paste(2004, rep(1:4, 4:1), seq(1,20,2), sep = "-")); x.date
x <- zoo(rnorm(12), x.date); x
# coarser dates - jan 1 (4 times), feb 1 (3 times), mar 1 (3 times)
x.date2 <- as.Date(paste(2004, rep(1:4, 4:1), 1, sep = "-")); x.date2
x2 <- aggregate(x, x.date2, mean); x2
# same - uses as.yearmon
x2a <- aggregate(x, as.Date(as.yearmon(time(x))), mean); x2a
# same - uses by function
x2b <- aggregate(x, function(tt) as.Date(as.yearmon(tt)), mean); x2b
# same - uses cut
x2c <- aggregate(x, as.Date(cut(time(x), "month")), mean); x2c
# almost same but times of x2d have yearmon class rather than Date class
x2d <- aggregate(x, as.yearmon, mean); x2d

# compare time series
plot(x)
lines(x2, col = 2)

## aggregate a daily time series to a quarterly series
# create zoo series
tt <- as.Date("2000-1-1") + 0:300
z.day <- zoo(0:300, tt)

# function which returns corresponding first "Date" of quarter
first.of.quarter <- function(tt) as.Date(as.yearqtr(tt))
```

```

# average z over quarters
# 1. via "yearqtr" index (regular)
# 2. via "Date" index (not regular)
z.qtr1 <- aggregate(z.day, as.yearqtr, mean)
z.qtr2 <- aggregate(z.day, first.of.quarter, mean)

# The last one used the first day of the quarter but suppose
# we want the first day of the quarter that exists in the series
# (and the series does not necessarily start on the first day
# of the quarter).
z.day[!duplicated(as.yearqtr(time(z.day)))]

# This is the same except it uses the last day of the quarter.
# It requires R 2.6.0 which introduced the fromLast= argument.
## Not run:
z.day[!duplicated(as.yearqtr(time(z.day)), fromLast = TRUE)]

## End(Not run)

# The aggregated series above are of class "zoo" (because z.day
# was "zoo"). To create a regular series of class "zooreg",
# the frequency can be automatically chosen
zr.qtr1 <- aggregate(z.day, as.yearqtr, mean, regular = TRUE)
# or specified explicitly
zr.qtr2 <- aggregate(z.day, as.yearqtr, mean, frequency = 4)

## aggregate on month and extend to monthly time series
if(require(chron)) {
y <- zoo(matrix(11:15, nrow = 5, ncol = 2), chron(c(15, 20, 80, 100, 110)))
colnames(y) <- c("A", "B")

# aggregate by month using first of month as times for coarser series
# using first day of month as representative time
y2 <- aggregate(y, as.Date(as.yearmon(time(y))), head, 1)

# fill in missing months by merging with an empty series containing
# a complete set of 1st of the months
yrt2 <- range(time(y2))
y0 <- zoo(seq(from = yrt2[1], to = yrt2[2], by = "month"))
merge(y2, y0)
}

# given daily series keep only first point in each month at
# day 21 or more
z <- zoo(101:200, as.Date("2000-01-01") + seq(0, length = 100, by = 2))
zz <- z[as.numeric(format(time(z), "%d")) >= 21]
zz[!duplicated(as.yearmon(time(zz)))]

# same except times are of "yearmon" class
aggregate(zz, as.yearmon, head, 1)

# aggregate POSIXct seconds data every 10 minutes

```

```

tt <- seq(10, 2000, 10)
x <- zoo(tt, structure(tt, class = c("POSIXt", "POSIXct")))
aggregate(x, time(x) - as.numeric(time(x)) %% 600, mean)

# aggregate weekly series to a series with frequency of 52 per year
set.seed(1)
z <- zooreg(1:100 + rnorm(100), start = as.Date("2001-01-01"), deltat = 7)

# new.freq() converts dates to a grid of freq points per year
# yd is sequence of dates of firsts of years
# yy is years sequence
# last line interpolates so dates, d, are transformed to year + frac of year
# so first week of 2001 is 2001.0, second week is 2001 + 1/52, third week
# is 2001 + 2/52, etc.
new.freq <- function(d, freq = 52) {
  y <- as.Date(cut(range(d), "years")) + c(0, 367)
  yd <- seq(y[1], y[2], "year")
  yy <- as.numeric(format(yd, "%Y"))
  floor(freq * approx(yd, yy, xout = d)$y) / freq
}

# take last point in each period
aggregate(z, new.freq, tail, 1)

# or, take mean of all points in each
aggregate(z, new.freq, mean)

# example of taking means in the presence of NAs
z.na <- zooreg(c(1:364, NA), start = as.Date("2001-01-01"))
aggregate(z.na, as.yearqtr, mean, na.rm = TRUE)

# Find the sd of all days that lie in any Jan, all days that lie in
# any Feb, ..., all days that lie in any Dec (i.e. output is vector with
# 12 components)
aggregate(z, format(time(z), "%m"), sd)

```

---

as.zoo

*Coercion from and to zoo*

---

## Description

Methods for coercing "zoo" objects to other classes and a generic function `as.zoo` for coercing objects to class "zoo".

## Usage

```
as.zoo(x, ...)
```

**Arguments**

`x` an object,  
`...` further arguments passed to `zoo` when the return object is created.

**Details**

`as.zoo` currently has a default method and methods for `ts`, `its`, `fts`, `irts`, `mcmc`, `tis`, `xts` objects (and `zoo` objects themselves).

Methods for coercing objects of class "zoo" to other classes currently include: `as.ts`, `as.matrix`, `as.vector`, `as.data.frame`, `as.list` (the latter also being available for "ts" objects).

In the conversion between `zoo` and `ts`, the `zooreg` class is always used.

**Value**

`as.zoo` returns a `zoo` object.

**See Also**

`zoo`, `zooreg`, `ts`, `its`, `irts`, `tis`, `fts`, `mcmc`, `xts`.

**Examples**

```
## coercion to zoo:
## default method
as.zoo(rnorm(5))
## method for "ts" objects
as.zoo(ts(rnorm(5), start = 1981, freq = 12))

## coercion from zoo:
x.date <- as.POSIXct(paste("2003-", rep(1:4, 4:1), "-", sample(1:28, 10, replace = TRUE), sep = ""))
x <- zoo(matrix(rnorm(24), ncol = 2), x.date)
as.matrix(x)
as.vector(x)
as.data.frame(x)
as.list(x)
```

**Description**

Generic functions for extracting the core data contained in a (more complex) object and replacing it.

**Usage**

```
coredata(x, ...)
coredata(x) <- value
```

**Arguments**

x                    an object.  
...                  further arguments passed to methods.  
value                a suitable value object for use with x.

**Value**

In zoo, there are currently coredata methods for time series objects of class "zoo", "ts", "its", "irts", all of which strip off the index/time attributes and return only the observations. The are also corresponding replacement methods for these classes.

**See Also**

[zoo](#)

**Examples**

```
x.date <- as.Date(paste(2003, rep(1:4, 4:1), seq(1,20,2), sep = "-"))
x <- zoo(matrix(rnorm(20), ncol = 2), x.date)

## the full time series
x
## and only matrix of observations
coredata(x)

## change the observations
coredata(x) <- matrix(1:20, ncol = 2)
x
```

---

frequency<-

*Replacing the Index of Objects*

---

**Description**

Generic function for replacing the frequency of an object.

**Usage**

```
frequency(x) <- value
```

**Arguments**

x                    an object.  
value                a frequency.

**Details**

frequency<- is a generic function for replacing (or assigning) the frequency of an object. Currently, there is a "zooreg" and a "zoo" method. In both cases, the value is assigned to the "frequency" of the object if it complies with the index(x).

**See Also**

[zooreg](#), [index](#)

**Examples**

```
z <- zooreg(1:5)
z
as.ts(z)
frequency(z) <- 3
z
as.ts(z)
```

---

index

*Extracting/Replacing the Index of Objects*

---

**Description**

Generic functions for extracting the index of an object and replacing it.

**Usage**

```
index(x, ...)
index(x) <- value
```

**Arguments**

x	an object.
...	further arguments passed to methods.
value	an ordered vector of the same length as the "index" attribute of x.

**Details**

index is a generic function for extracting the index of objects, currently it has a default method and a method for zoo objects which is the same as the time method for zoo objects. Another pair of generic functions provides replacing the index or time attribute. Methods are available for "zoo" objects only, see examples below.

The start and end of the index/time can be queried by using the methods of start and end.

**See Also**

[time](#), [zoo](#)

**Examples**

```
x.date <- as.Date(paste(2003, 2, c(1, 3, 7, 9, 14), sep = "-"))
x <- zoo(rnorm(5), x.date)

## query index/time of a zoo object
index(x)
time(x)

## change class of index from Date to POSIXct
## relative to current time zone
x
index(x) <- as.POSIXct(format(time(x)),tz="")
x

## replace index/time of a zoo object
index(x) <- 1:5
x
time(x) <- 6:10
x

## query start and end of a zoo object
start(x)
end(x)

## query index of a usual matrix
xm <- matrix(rnorm(10), ncol = 2)
index(xm)
```

---

is.regular

*Check Regularity of a Series*

---

**Description**

is.regular is a regular function for checking whether a series of ordered observations has an underlying regularity or is even strictly regular.

**Usage**

```
is.regular(x, strict = FALSE)
```

**Arguments**

x                    an object (representing a series of ordered observations).  
strict                logical. Should strict regularity be checked? See details.

## Details

A time series can either be irregular (unequally spaced), strictly regular (equally spaced) or have an underlying regularity, i.e., be created from a regular series by omitting some observations. Here, the latter property is called *regular*. Consequently, regularity follows from strict regularity but not vice versa.

`is.regular` is a generic function for checking regularity (default) or strict regularity. Currently, it has methods for "ts" objects (which are always strictly regular), "zooreg" objects (which are at least regular), "zoo" objects (which can be either irregular, regular or even strictly regular) and a default method. The latter coerces `x` to "zoo" before checking its regularity.

## Value

A logical is returned indicating whether `x` is (strictly) regular.

## See Also

[zooreg](#), [zoo](#)

## Examples

```
## checking of a strictly regular zoo series
z <- zoo(1:10, seq(2000, 2002.25, by = 0.25), frequency = 4)
z
class(z)
frequency(z) ## extraction of frequency attribute
is.regular(z)
is.regular(z, strict = TRUE)
## by omitting observations, the series is not strictly regular
is.regular(z[-3])
is.regular(z[-3], strict = TRUE)

## checking of a plain zoo series without frequency attribute
## which is in fact regular
z <- zoo(1:10, seq(2000, 2002.25, by = 0.25))
z
class(z)
frequency(z) ## data driven computation of frequency
is.regular(z)
is.regular(z, strict = TRUE)
## by omitting observations, the series is not strictly regular
is.regular(z[-3])
is.regular(z[-3], strict = TRUE)

## checking of an irregular zoo series
z <- zoo(1:10, rnorm(10))
z
class(z)
frequency(z) ## attempt of data-driven frequency computation
is.regular(z)
is.regular(z, strict = TRUE)
```

lag.zoo

*Lags and Differences of zoo Objects***Description**

Methods for computing lags and differences of "zoo" objects.

**Usage**

```
## S3 method for class 'zoo'
lag(x, k = 1, na.pad = FALSE, ...)
## S3 method for class 'zoo'
diff(x, lag = 1, differences = 1, arithmetic = TRUE, na.pad = FALSE, ...)
```

**Arguments**

x	a "zoo" object.
k, lag	For lag the number of lags (in units of observations). Note the sign of k behaves as in <code>lag</code> . For diff it is the number of backward lags used (or if negative the number of forward lags).
differences	an integer indicating the order of the difference.
arithmetic	logical. Should arithmetic (or geometric) differences be computed?
na.pad	logical. If TRUE it adds any times that would not otherwise have been in the result with a value of NA. If FALSE those times are dropped.
...	currently not used.

**Details**

These methods for "zoo" objects behave analogously to the default methods. The only additional arguments are `arithmetic` in `diff` `na.pad` in `lag.zoo` which can also be specified in `diff.zoo` as part of the dots. Also, "k" can be a vector of lags in which case the names of "k", if any, are used in naming the result.

**Value**

The lagged or differenced "zoo" object.

**Note**

Note the sign of k: a series lagged by a positive k is shifted *earlier* in time.

`lag.zoo` and `lag.zooreg` can give different results. For a lag of 1 `lag.zoo` moves points to the adjacent time point whereas `lag.zooreg` moves the time by `deltat`. This implies that a point in a zoo series cannot be lagged to a time point that is not already in the series whereas this is possible for a zooreg series.

**See Also**

[zoo](#), [lag](#), [diff](#)

**Examples**

```
x <- zoo(11:21)

lag(x, k = 1)
lag(x, k = -1)
# this pairs each value of x with the next or future value
merge(x, lag1 = lag(x, k=1))
diff(x^3)
diff(x^3, -1)
diff(x^3, na.pad = TRUE)
```

---

make.par.list

*Make a List from a Parameter Specification*

---

**Description**

Process parameters so that a list of parameter specifications is returned (used by `plot.zoo` and `xyplot.zoo`).

**Usage**

```
make.par.list(nams, x, n, m, def, recycle = sum(unnamed) > 0)
```

**Arguments**

nams	character vector with names of variables.
x	list or vector of parameter specifications, see details.
n	numeric, number of rows.
m	numeric, number of columns. (Only determines whether m is 1 or greater than 1.
def	default parameter value.
recycle	logical. If TRUE recycle columns to provide unspecified ones. If FALSE use def to provide unspecified ones. This only applies to entire columns. Within columns recycling is always done regardless of how recycle is set. Defaults to TRUE if there is at least one unnamed variable and defaults to FALSE if there are only named variables in x.

**Details**

This function is currently intended for internal use. It is currently used by `plot.zoo` and `xyplot.zoo` but might also be used in the future to create additional new plotting routines. It creates a new list which uses the named variables from `x` and then assigns the unnamed in order. For the remaining variables assign them the default value if `!recycle` or recycle the unnamed variables if `recycle`.

**Value**

A list of parameters, see details.

**Examples**

```
make.par.list(letters[1:5], 1:5, 3, 5)
suppressWarnings( make.par.list(letters[1:5], 1:4, 3, 5, 99) )
make.par.list(letters[1:5], c(d=3), 3, 5, 99)
make.par.list(letters[1:5], list(d=1:2, 99), 3, 5)
make.par.list(letters[1:5], list(d=1:2, 99, 100), 3, 5)
```

MATCH

*Value Matching***Description**

MATCH is a generic function for value matching.

**Usage**

```
MATCH(x, table, nomatch = NA, ...)
## S3 method for class 'times'
MATCH(x, table, nomatch = NA, units = "sec", eps = 1e-10, ...)
```

**Arguments**

x	an object.
table	the values to be matched against.
nomatch	the value to be returned in the case when no match is found. Note that it is coerced to integer.
units	See <a href="#">trunc.times</a> .
eps	See <a href="#">trunc.times</a> .
...	further arguments to be passed to methods.

**Details**

MATCH is a new generic function which aims at providing the functionality of the non-generic base function [match](#) for arbitrary objects. Currently, there is only a default method which simply calls [match](#).

MATCH.times is used for chron objects. x will match any time in table less than units away.

**See Also**

[match](#)

**Examples**

```
MATCH(1:5, 2:3)
```

merge.zoo

*Merge Two or More zoo Objects***Description**

Merge two zoo objects by common indexes (times), or do other versions of database *join* operations.

**Usage**

```
## S3 method for class 'zoo'
merge(..., all = TRUE, fill = NA, suffixes = NULL,
       check.names = FALSE, retclass = c("zoo", "list", "data.frame"),
       drop = TRUE)
```

**Arguments**

...	two or more objects, usually of class "zoo".
all	logical vector having the same length as the number of "zoo" objects to be merged (otherwise expanded).
fill	an element for filling gaps in merged "zoo" objects (if any).
suffixes	character vector of the same length as the number of "zoo" objects specifying the suffixes to be used for making the merged column names unique.
check.names	See link{read.table}.
retclass	character that specifies the class of the returned result. It can be "zoo" (the default), "list" or NULL. For details see below.
drop	logical. If a "zoo" object without observations is merged with a one-dimensional "zoo" object (vector or 1-column matrix), should the result be a vector (drop = TRUE) or a 1-column matrix (drop = FALSE)? The former is the default in the Merge method, the latter in the cbind method.

**Details**

The merge method for "zoo" objects combines the columns of several objects along the union of the dates for `all = TRUE`, the default, or the intersection of their dates for `all = FALSE` filling up the created gaps (if any) with the `fill` pattern.

The first argument must be a zoo object. If any of the remaining arguments are plain vectors or matrices with the same length or number of rows as the first argument then such arguments are coerced to "zoo" using `as.zoo`. If they are plain but have length 1 then they are merged after all non-scalars such that their column is filled with the value of the scalar.

`all` can be a vector of the same length as the number of "zoo" objects to merged (if not, it is expanded): All indexes (times) of the objects corresponding to `TRUE` are included, for those corresponding to `FALSE` only the indexes present in all objects are included. This allows intersection, union and left and right joins to be expressed.

If `retclass` is "zoo" (the default) a single merged "zoo" object is returned. If it is set to "list" a list of "zoo" objects is returned. If `retclass = NULL` then instead of returning a value it updates

each argument (if it is a variable rather than an expression) in place so as to extend or reduce it to use the common index vector.

The indexes of different "zoo" objects can be of different classes and are coerced to one class in the resulting object (with a warning).

The default cbind method is essentially the default merge method, but does not support the retclass argument. The rbind method combines the dates of the "zoo" objects (duplicate dates are not allowed) and combines the rows of the objects. Furthermore, the c method is identical to the rbind method.

## Value

An object of class "zoo" if retclass="zoo", an object of class "list" if retclass="list" or modified arguments as explained above if retclass=NULL. If the result is an object of class "zoo" then its frequency is the common frequency of its zoo arguments, if they have a common frequency.

## See Also

[zoo](#)

## Examples

```
## simple merging
x.date <- as.Date(paste(2003, 02, c(1, 3, 7, 9, 14), sep = "-"))
x <- zoo(rnorm(5), x.date)

y1 <- zoo(matrix(1:10, ncol = 2), 1:5)
y2 <- zoo(matrix(rnorm(10), ncol = 2), 3:7)

## using arguments 'fill' and 'suffixes'
merge(y1, y2, all = FALSE)
merge(y1, y2, all = FALSE, suffixes = c("a", "b"))
merge(y1, y2, all = TRUE)
merge(y1, y2, all = TRUE, fill = 0)

## if different index classes are merged, as in
## the next merge example then ## a warning is issued and
### the indexes are coerced.
## It is up to the user to ensure that the result makes sense.
merge(x, y1, y2, all = TRUE)

## extend an irregular series to a regular one:
# create a constant series
z <- zoo(1, seq(4)[-2])
# create a 0 dimensional zoo series
z0 <- zoo(, 1:4)
# do the extension
merge(z, z0)
# same but with zero fill
merge(z, z0, fill = 0)

merge(z, coredata(z), 1)
```

```

## merge multiple series represented in a long form data frame
## into a multivariate zoo series and plot, one series for each site.
## Additional examples can be found here:

---

na.aggregate

*Replace NA by Aggregation*

---

### Description

Generic function for replacing each NA with aggregated values. This allows imputing by the overall mean, by monthly means, etc.

### Usage

```

na.aggregate(object, ...)
## Default S3 method:
na.aggregate(object, by = 1, ..., FUN = mean,
              na.rm = FALSE, maxgap = Inf)

```

**Arguments**

object	an object.
by	a grouping variable corresponding to object, or a function to be applied to time(object) to generate the groups.
...	further arguments passed to by if by is a function.
FUN	function to apply to the non-missing values in each group defined by by.
na.rm	logical. Should any remaining NAs be removed?
maxgap	maximum number of consecutive NAs to fill. Any longer gaps will be left unchanged.

**Value**

An object in which each NA in the input object is replaced by the mean (or other function) of its group, defined by by. This is done for each series in a multi-column object. Common choices for the aggregation group are a year, a month, all calendar months, etc.

If a group has no non-missing values, the default aggregation function mean will return NaN. Specify na.rm = TRUE to omit such remaining missing values.

**See Also**

[zoo](#)

**Examples**

```
z <- zoo(c(1, NA, 3:9),
        c(as.Date("2010-01-01") + 0:2,
          as.Date("2010-02-01") + 0:2,
          as.Date("2011-01-01") + 0:2))
## overall mean
na.aggregate(z)
## group by months
na.aggregate(z, as.yearmon)
## group by calendar months
na.aggregate(z, months)
## group by years
na.aggregate(z, format, "%Y")
```

---

na.approx

*Replace NA by Interpolation*

---

**Description**

Generic functions for replacing each NA with interpolated values.

**Usage**

```

na.approx(object, ...)
## S3 method for class 'zoo'
na.approx(object, x = index(object), xout, ..., na.rm = TRUE, along)
## S3 method for class 'zooreg'
na.approx(object, ...)
## S3 method for class 'ts'
na.approx(object, ...)
## Default S3 method:
na.approx(object, x = index(object), xout, ..., na.rm = TRUE, maxgap = Inf, along)

na.spline(object, ...)
## S3 method for class 'zoo'
na.spline(object, x = index(object), xout, ..., na.rm = TRUE, along)
## S3 method for class 'zooreg'
na.spline(object, ...)
## S3 method for class 'ts'
na.spline(object, ...)
## Default S3 method:
na.spline(object, x = index(object), xout, ..., na.rm = TRUE, maxgap = Inf, along)

```

**Arguments**

object	object in which NAs are to be replaced
x, xout	Variables to be used for interpolation as in <a href="#">approx</a> .
na.rm	logical. Should leading NAs be removed?
maxgap	maximum number of consecutive NAs to fill. Any longer gaps will be left unchanged. Note that all methods listed above can accept maxgap as it is ultimately passed to the default method.
along	deprecated.
...	further arguments passed to methods. The n argument of <a href="#">approx</a> is currently not supported.

**Details**

Missing values (NAs) are replaced by linear interpolation via [approx](#) or cubic spline interpolation via [spline](#), respectively.

It can also be used for series disaggregation by specifying xout.

By default the index associated with object is used for interpolation. Note, that if this calls `index.default` this gives an equidistant spacing `1:NROW(object)`. If object is a matrix or data.frame, the interpolation is done separately for each column.

If obj is a plain vector then `na.approx(obj, x, y, xout, ...)` returns `approx(x = x[!na], y = coredata(obj)[!na], xout = xout, ...)` (where na indicates observations with NA) such that xout defaults to x.

If obj is a zoo, zooreg or ts object its coredata value is processed as described and its time index is xout if specified and index(obj) otherwise. If obj is two dimensional then the above is applied to each column separately. For examples, see below.

If obj has more than one column, the above strategy is applied to each column.

### Value

An object of similar structure as object with (internal) NAs replaced by interpolation. Leading or trailing NAs are omitted if na.rm = TRUE or not replaced if na.rm = FALSE.

### See Also

### Examples

```
z <- zoo(c(2, NA, 1, 4, 5, 2), c(1, 3, 4, 6, 7, 8))

## use underlying time scale for interpolation
na.approx(z)
## use equidistant spacing
na.approx(z, 1:6)

# with and without na.rm = FALSE
zz <- c(NA, 9, 3, NA, 3, 2)
na.approx(zz, na.rm = FALSE)
na.approx(zz)

d0 <- as.Date("2000-01-01")
z <- zoo(c(11, NA, 13, NA, 15, NA), d0 + 1:6)

# NA fill, drop or keep leading/trailing NAs
na.approx(z)
na.approx(z, na.rm = FALSE)

# extrapolate to point outside of range of time points
# (a) drop NA, (b) keep NA, (c) extrapolate using rule = 2 from approx()
na.approx(z, xout = d0 + 7)
na.approx(z, xout = d0 + 7, na.rm = FALSE)
na.approx(z, xout = d0 + 7, rule = 2)

# use splines - extrapolation handled differently
z <- zoo(c(11, NA, 13, NA, 15, NA), d0 + 1:6)
na.spline(z)
na.spline(z, na.rm = FALSE)
na.spline(z, xout = d0 + 1:6)
na.spline(z, xout = d0 + 2:5)
na.spline(z, xout = d0 + 7)
na.spline(z, xout = d0 + 7, na.rm = FALSE)

## using na.approx for disaggregation
```

```

zy <- zoo(1:3, 2000:2001)

# yearly to monthly series
zmo <- na.approx(zy, xout = as.yearmon(2000+0:13/12))
zmo

# monthly to daily series
sq <- seq(as.Date(start(zmo)), as.Date(end(zmo), frac = 1), by = "day")
zd <- na.approx(zmo, x = as.Date, xout = sq)
head(zd)

# weekly to daily series
zww <- zoo(1:3, as.Date("2001-01-01") + seq(0, length = 3, by = 7))
zww
zdd <- na.approx(zww, xout = seq(start(zww), end(zww), by = "day"))
zdd

# The lines do not show up because of the NAs
plot(cbind(z, z), type = "b", screen = 1)
# use na.approx to force lines to appear
plot(cbind(z, na.approx(z)), type = "b", screen = 1)

# Workaround where less than 2 NAs can appear in a column
za <- zoo(cbind(1:5, NA, c(1:3, NA, 5), NA)); za

ix <- colSums(!is.na(za)) > 0
za[, ix] <- na.approx(za[, ix]); za

# using na.approx to create regularly spaced series
# z has points at 10, 20 and 40 minutes while output also has a point at 30
if(require("chron")) {
  tt <- as.chron("2000-01-01 10:00:00") + c(1, 2, 4) * as.numeric(times("00:10:00"))
  z <- zoo(1:3, tt)
  tseq <- seq(start(z), end(z), by = times("00:10:00"))
  na.approx(z, xout = tseq)
}

```

---

na.fill

*Fill NA or specified positions.*

---

## Description

Generic function for filling NA values or specified positions.

## Usage

```

na.fill(object, fill, ...)
## S3 method for class 'ts'
na.fill(object, fill, ix, ...)
## S3 method for class 'zoo'

```

```
na.fill(object, fill, ix, ...)
## Default S3 method:
na.fill(object, fill, ix, ...)
```

### Arguments

object	an object.
fill	a three component list or a vector that is coerced to a list. Shorter objects are recycled. The three components represent the fill value to the left of the data, within the interior of the data and to the right of the data, respectively. The value of any component may be the keyword "extend" to indicate repetition of the leftmost or rightmost non-NA value or linear interpolation in the interior. NULL means that items are dropped rather than filled.
ix	logical. Should be the same length as the number of time points. Indicates which time points not to fill. This defaults to the non-NA values.
...	further arguments passed to methods.

### Details

Fill NA or indicated values.

### See Also

[na.approx](#)

### Examples

```
z <- zoo(c(NA, 2, NA, 1, 4, 5, 2, NA))
na.fill(z, "extend")
na.fill(z, c("extend", NA))
na.fill(z, -(1:3))
na.fill(z, list(NA, NULL, NA))
```

---

na.locf

*Last Observation Carried Forward*

---

### Description

Generic function for replacing each NA with the most recent non-NA prior to it.

### Usage

```
na.locf(object, na.rm = TRUE, ...)
## Default S3 method:
na.locf(object, na.rm = TRUE, fromLast, rev,
         maxgap = Inf, rule = 2, ...)
```

**Arguments**

object	an object.
na.rm	logical. Should leading NAs be removed?
fromLast	logical. Causes observations to be carried backward rather than forward. Default is FALSE. With a value of TRUE this corresponds to NOCB (next observation carried backward). It is not supported if x or xout is specified.
rev	Use fromLast instead. This argument will be eliminated in the future in favor of fromLast.
maxgap	Runs of more than maxgap NAs are retained, other NAs are removed and the last occurrence in the resulting series prior to each time point in xout is used as that time point's output value. (If xout is not specified this reduces to retaining runs of more than maxgap NAs while filling other NAs with the last occurrence of a non-NA.)
rule	See <a href="#">approx</a> .
...	further arguments passed to methods.

**Value**

An object in which each NA in the input object is replaced by the most recent non-NA prior to it. If there are no earlier non-NAs then the NA is omitted (if `na.rm = TRUE`) or it is not replaced (if `na.rm = FALSE`).

The arguments `x` and `xout` can be used in which case they have the same meaning as in [approx](#).

Note that if a multi-column zoo object has a column entirely composed of NA then with `na.rm = TRUE`, the default, the above implies that the resulting object will have zero rows. Use `na.rm = FALSE` to preserve the NA values instead.

**See Also**

13258, 13259, 13262, 13263, 13264, 13265, 13266, 13269, 13270,
13271, 13272, 13274)))

# z.na is same as z but with missing days added (with NAs)
# It is formed by merging z with a zero with series having all the dates.

rng <- range(time(z))
z.na <- merge(z, zoo(, seq(rng[1], rng[2], by = "day")))

# use na.locf to bring values forward picking off 5th of month
na.locf(z.na)[as.POSIXlt(time(z.na))$mday == 5]

## this is the same as the last one except instead of always using the
## 5th of month in the result we show the date actually used

# idx has NAs wherever z.na does but has 1, 2, 3, ... instead of
# z.na's data values (so idx can be used for indexing)

idx <- coredata(na.locf(seq_along(z.na) + (0 * z.na)))

# pick off those elements of z.na that correspond to 5th

z.na[idx[as.POSIXlt(time(z.na))$mday == 5]]

## only fill single-day gaps

merge(z.na, filled1 = na.locf(z.na, maxgap = 1))

## fill NAs in first column by inflating the most recent non-NA
## by the growth in second column. Note that elements of x-x
## are NA if the corresponding element of x is NA and zero else

m <- zoo(cbind(c(1, 2, NA, NA, 5, NA, NA), seq(7)^2), as.Date(1:7))

```

```

r <- na.locf(m[,1]) * m[,2] / na.locf(m[,2] + (m[,1]-m[,1]))
cbind(V1 = r, V2 = m[,2])

## repeat a quarterly value every month
## preserving NAs
zq <- zoo(c(1, NA, 3, 4), as.yearqtr(2000) + 0:3/4)
tt <- as.yearmon(start(zq)) + seq(0, len = 3 * length(zq))/12
na.locf(zq, xout = tt, maxgap = 0)

```

---

na.StructTS

*Fill NA or specified positions.*

---

### Description

Generic function for filling NA values using seasonal Kalman filter.

### Usage

```

na.StructTS(object, ...)
## S3 method for class 'ts'
na.StructTS(object, ..., na.rm = FALSE, maxgap = Inf)
## S3 method for class 'zoo'
na.StructTS(object, ..., na.rm = FALSE, maxgap = Inf)

```

### Arguments

object	an object.
...	other arguments passed to methods.
na.rm	logical. Whether to remove end portions or fill them with NA.
maxgap	Runs of more than maxgap NAs are retained, other NAs are removed and the last occurrence in the resulting series prior to each time point in xout is used as that time point's output value.

### Details

Interpolate with seasonal Kalman filter. The input object should have a frequency. It is assumed the cycle length is 1.

### See Also

[na.approx](#)

**Examples**

```

z <- zooreg(rep(10 * seq(4), each = 4) + rep(c(3, 1, 2, 4), times = 4),
start = as.yearqtr(2000), freq = 4)
z[10] <- NA

zout <- na.StructTS(z)

plot(cbind(z, zout), screen = 1, col = 1:2, type = c("l", "p"), pch = 20)

```

na.trim

*Trim Leading/Trailing Missing Observations***Description**

Generic function for removing leading and trailing NAs.

**Usage**

```

na.trim(object, ...)
## Default S3 method:
na.trim(object, sides = c("both", "left", "right"),
is.na = c("any", "all"), ...)

```

**Arguments**

object	an object.
sides	character specifying whether NAs are to be removed from both sides, just from the left side or just from the right side.
is.na	If "any" then a row will be regarded as NA if it has any NAs. If "all" then a row will be regarded as NA only if all elements in the row are NA. For one dimensional zoo objects this argument has no effect.
...	further arguments passed to methods.

**Value**

An object in which leading and/or trailing NAs have been removed.

**See Also**

**Examples**

```
# examples of na.trim
x <- zoo(c(1, 4, 6), c(2, 4, 6))
xx <- zoo(matrix(c(1, 4, 6, NA, 5, 7), 3), c(2, 4, 6))
na.trim(x)
na.trim(xx)

# using na.trim for alignment
# cal defines the legal dates
# all dates within the date range of x should be present
cal <- zoo(c(1, 2, 3, 6, 7))
x <- zoo(c(12, 16), c(2, 6))
na.trim(merge(x, cal))
```

---

ORDER

*Ordering Permutation*

---

**Description**

ORDER is a generic function for computing ordering permutations.

**Usage**

```
ORDER(x, ...)
## Default S3 method:
ORDER(x, ..., na.last = TRUE, decreasing = FALSE)
```

**Arguments**

x	an object.
...	further arguments to be passed to methods.
na.last	for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed.
decreasing	logical. Should the sort order be increasing or decreasing?

**Details**

ORDER is a new generic function which aims at providing the functionality of the non-generic base function `order` for arbitrary objects. Currently, there is only a default method which simply calls `order`. For objects (more precisely if `is.object` is TRUE) `order` leverages the generic `xtfrm`. Thus, to assure ordering works, one can supply either a method to `xtfrm` or to `ORDER` (or both).

**See Also**

[order](#)

**Examples**

```
ORDER(rnorm(5))
```

---

plot.zoo

*Plotting zoo Objects*

---

**Description**

Plotting method for objects of class "zoo".

**Usage**

```
## S3 method for class 'zoo'
plot(x, y = NULL, screens, plot.type,
     panel = lines, xlab = "Index", ylab = NULL, main = NULL,
     xlim = NULL, ylim = NULL, xy.labels = FALSE, xy.lines = NULL,
     yax.flip = FALSE, oma = c(6, 0, 5, 0),
     mar = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
     col = 1, lty = 1, lwd = 1, pch = 1, type = "l", log = "",
     nc, widths = 1, heights = 1, ...)
## S3 method for class 'zoo'
lines(x, y = NULL, type = "l", ...)
## S3 method for class 'zoo'
points(x, y = NULL, type = "p", ...)
```

**Arguments**

x	an object of class "zoo".
y	an object of class "zoo". If y is NULL (the default) a time series plot of x is produced, otherwise if both x and y are univariate "zoo" series, a scatter plot of y versus x is produced.
screens	factor (or coerced to factor) whose levels specify which graph each series is to be plotted in. screens=c(1,2,1) would plot series 1, 2 and 3 in graphs 1, 2 and 1. If not specified then 1 is used if plot.type="single" and seq_len(ncol(x)) otherwise.
plot.type	for multivariate zoo objects, "multiple" plots the series on multiple plots and "single" superimposes them on a single plot. Default is "single" if screens has only one level and "multiple" otherwise. If neither screens nor plot.type is specified then "single" is used if there is one series and "multiple" otherwise. This option is provided for back compatibility. Usually screens is used instead.
panel	a function(x, y, col, lty, ...) which gives the action to be carried out in each panel of the display for plot.type = "multiple".
ylim	if plot.type = "multiple" then it can be a list of y axis limits. If not a list each graph has the same limits. If any list element is not a pair then its range is used instead. If plot.type = "single" then it is as in plot.

<code>xy.labels</code>	logical, indicating if <code>text</code> labels should be used in the scatter plot, or character, supplying a vector of labels to be used.
<code>xy.lines</code>	logical, indicating if <code>lines</code> should be drawn in the scatter plot. Defaults to the value of <code>xy.labels</code> if that is logical, otherwise to <code>FALSE</code> .
<code>yax.flip</code>	logical, indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when <code>type = "multiple"</code> .
<code>xlab, ylab, main, xlim, oma, mar</code>	graphical arguments, see <code>par</code> .
<code>col, lty, lwd, pch, type</code>	graphical arguments that can be vectors or (named) lists. See the details for more information.
<code>log</code>	specification of log scales as "x", "y" or "xy".
<code>nc</code>	the number of columns to use when <code>plot.type = "multiple"</code> . Defaults to 1 for up to 4 series, otherwise to 2.
<code>widths, heights</code>	widths and heights for individual graphs, see <code>layout</code> .
<code>...</code>	additional graphical arguments.

## Details

The methods for `plot` and `lines` are very similar to the corresponding `ts` methods. However, the handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1,2), c(3,4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way. If `plot.type` and `screens` conflict then multiple plots will be assumed. Also see the examples.

In the case of a custom panel the panel can reference `parent.frame$panel.number` in order to determine which frame the panel is being called from. See examples.

`par(mfrow=...)` and `Axis` can be used in conjunction with single panel plots in the same way as with other classic graphics.

For multi-panel graphics, `plot.zoo` takes over the layout so `par(mfrow=...)` cannot be used. `Axis` can be used within the panels themselves but not outside the panel. See examples.

In addition to classical time series line plots, there is also a simple `barplot` method for "zoo" series.

---

read.zoo

*Reading and Writing zoo Series*

---

## Description

read.zoo and write.zoo are convenience functions for reading and writing "zoo" series from/to text files. They are convenience interfaces to read.table and write.table, respectively.

## Usage

```

read.zoo(file, format = "", tz = "", FUN = NULL,
  regular = FALSE, index.column = 1, drop = TRUE, FUN2 = NULL,
  split = NULL, aggregate = FALSE, ..., text)
write.zoo(x, file = "", index.name = "Index", row.names = FALSE, col.names = NULL, ...)

```

## Arguments

**file** character string or strings giving the name of the file(s) which the data are to be read from/written to. See [read.table](#) and [write.table](#) for more information. Alternatively, in read.zoo, file can be a connection or a data.frame (e.g., resulting from a previous read.table call) that is subsequently processed to a "zoo" series.

format	date format argument passed to FUN.
tz	time zone argument passed to <a href="#">as.POSIXct</a> .
FUN	a function for computing the index from the first column of the data. See details.
regular	logical. Should the series be coerced to class "zooreg" (if the series is regular)?
index.column	numeric vector or list. The column names or numbers of the data frame in which the index/time is stored. If the <code>read.table colClasses</code> argument is used and "NULL" is among its components then <code>index.column</code> refers to the column numbers after the columns corresponding to "NULL" in <code>colClasses</code> have been removed. If specified as a list then one argument will be passed to argument FUN per component so that, for example, <code>index.column = list(1, 2)</code> will cause <code>FUN(x[,1], x[,2], ...)</code> to be called whereas <code>index.column = list(1:2)</code> will cause <code>FUN(x[,1:2], ...)</code> to be called where <code>x</code> is a data frame of characters data. Here <code>...</code> refers to <code>format</code> and/or <code>tz</code> , if they specified as arguments. <code>index.column = 0</code> can be used to specify that the row names be used as the index. In the case that no row names were input sequential numbering is used. If <code>index.column</code> is specified as an ordinary vector then if it has the same length as the number of arguments of FUN (or FUN2 in the event that FUN2 is specified and FUN is not) then <code>index.column</code> is converted to a list. Also it is always converted to a list if it has length 1.
drop	logical. If the data frame contains just a single data column, should the second dimension be dropped?
x	a "zoo" object.
index.name	character with name of the index column in the written data file.
row.names	logical. Should row names be written? Default is FALSE because the row names are just character representations of the index.
col.names	logical. Should column names be written? Default is to write column names only if <code>x</code> has column names.
FUN2	function. It is applied to the time index after FUN and before <code>aggregate</code> . If FUN is not specified but FUN2 is specified then only FUN2 is applied.
split	NULL or column number or name or vector of numbers or names. If not NULL then the data is assumed to be in long format and is split according to the indicated columns. See the R <a href="#">reshape</a> command for description of long data. If <code>split=Inf</code> then the first of each run are made into a separate series, the second of each run and so on. If <code>split=-Inf</code> then the last of each run is made into a separate series, the second last and so on.
aggregate	logical or function. If set to TRUE, then <a href="#">aggregate.zoo</a> is applied to the zoo object created to compute the <a href="#">mean</a> of all values with the same time index. Alternatively, <code>aggregate</code> can be set to any other function that should be used for aggregation. If FALSE (the default), no aggregation is performed and a warning is given if there are any duplicated time indexes. Note that most zoo functions do not accept objects with duplicate time indexes. See <a href="#">aggregate.zoo</a> .
...	further arguments passed to <a href="#">read.table</a> or <a href="#">write.table</a> , respectively.
text	See argument of same name in <a href="#">read.table</a> .

## Details

`read.zoo` is a convenience function which should make it easier to read data from a text file and turn it into a "zoo" series immediately. `read.zoo` reads the data file via `read.table(file, ...)`. The column `index.column` (by default the first) of the resulting data is interpreted to be the index/time, the remaining columns the corresponding data. (If the file only has only column then that is assumed to be the data column and 1, 2, ... are used for the index.) To assign the appropriate class to the index, `FUN` can be specified and is applied to the first column.

To process the index, `read.zoo` calls `FUN` with the index as the first argument. If `FUN` is not specified then if there are multiple index columns they are pasted together with a space between each. Using the index column or pasted index column: 1. If `tz` is specified then the index column is converted to `POSIXct`. 2. If `format` is specified then the index column is converted to `Date`. 3. Otherwise, a heuristic attempts to decide among "numeric", "Date" and "POSIXct". If `format` and/or `tz` is specified then they are passed to the conversion function as well.

If `regular` is set to `TRUE` and the resulting series has an underlying regularity, it is coerced to a "zooreg" series.

`write.zoo` is a convenience function for writing "zoo" series to text files. It first coerces its argument to a "data.frame", adds a column with the index and then calls `write.table`.

## Value

`read.zoo` returns an object of class "zoo" (or "zooreg").

## Note

`read.zoo` works by first reading the data in using `read.table` and then processing it. This implies that if the index field is entirely numeric the default is to pass it to `FUN` or the built-in date conversion routine a number, rather than a character string. Thus, a date field such as 09122007 intended to represent December 12, 2007 would be seen as 9122007 and interpreted as the 91st day thereby generating an error.

This comment also applies to trailing decimals so that if 2000.10 were intended to represent the 10th month of 2000 in fact it would receive 2000.1 and regard it as the first month of 2000 unless similar precautions were taken.

In the above cases the index field should be specified to be "character" so that leading or trailing zeros are not dropped. This can be done by specifying a "character" index column in the "colClasses" argument, which is passed to `read.table`, as shown in the examples below.

```

---

rollapply

*Apply Rolling Functions*

---

## Description

A generic function for applying a function to rolling margins of an array.

## Usage

```

rollapply(data, ...)
## S3 method for class 'ts'
rollapply(data, ...)
## S3 method for class 'zoo'
rollapply(data, width, FUN, ..., by = 1, by.column = TRUE,
          fill = if (na.pad) NA, na.pad = FALSE, partial = FALSE,
          align = c("center", "left", "right"))
## Default S3 method:
rollapply(data, ...)
rollapplyr(..., align = "right")

```

## Arguments

data	the data to be used (representing a series of observations).
width	numeric vector or list. In the simplest case this is an integer specifying the window width which is aligned to the original sample according to the align argument. Alternatively, width can be a list regarded as offsets compared to the current time, see below for details.

<code>FUN</code>	the function to be applied.
<code>...</code>	optional arguments to <code>FUN</code> .
<code>by</code>	calculate <code>FUN</code> at every <code>by</code> -th time point rather than every point. <code>by</code> is only used if <code>width</code> is length 1 and either a plain scalar or a list.
<code>by.column</code>	logical. If <code>TRUE</code> , <code>FUN</code> is applied to each column separately.
<code>fill</code>	a three-component vector or list (recycled otherwise) providing filling values at the left/within/to the right of the data range. See the <code>fill</code> argument of <a href="#">na.fill</a> for details.
<code>na.pad</code>	deprecated. Use <code>fill = NA</code> instead of <code>na.pad = TRUE</code> .
<code>partial</code>	logical or numeric. If <code>FALSE</code> (default) then <code>FUN</code> is only applied when all indexes of the rolling window are within the observed time range. If <code>TRUE</code> , then the subset of indexes that are in range are passed to <code>FUN</code> . A numeric argument to <code>partial</code> can be used to determine the minimal window size for partial computations. See below for more details.
<code>align</code>	specifies whether the index of the result should be left- or right-aligned or centered (default) compared to the rolling window of observations. This argument is only used if <code>width</code> represents widths.

## Details

If `width` is a plain numeric vector its elements are regarded as widths to be interpreted in conjunction with `align` whereas if `width` is a list its components are regarded as offsets. In the above cases if the length of `width` is 1 then `width` is recycled for every `by`-th point. If `width` is a list its components represent integer offsets such that the `i`-th component of the list refers to time points at positions `i + width[[i]]`. If any of these points are below 1 or above the length of `index(data)` then `FUN` is not evaluated for that point unless `partial = TRUE` and in that case only the valid points are passed.

The rolling function can also be applied to partial windows by setting `partial = TRUE`. For example, if `width = 3`, `align = "right"` then for the first point just that point is passed to `FUN` since the two points to its left are out of range. For the same example, if `partial = FALSE` then `FUN` is not invoked at all for the first two points. If `partial` is a numeric then it specifies the minimum number of offsets that must be within range. Negative `partial` is interpreted as `FALSE`.

If `FUN` is `mean`, `max` or `median` and `by.column` is `TRUE` and `width` is a plain scalar and there are no other arguments then special purpose code is used to enhance performance. Also in the case of `mean` such special purpose code is only invoked if the data argument has no NA values. See [rollmean](#), [rollmax](#) and [rollmedian](#) for more details.

Currently, there are methods for "zoo" and "ts" series and "default" method for ordinary vectors and matrices.

`rollapplyr` is a wrapper around `rollapply` that uses a default of `align = "right"`.

## Value

A object of the same class as `data` with the results of the rolling function.

## See Also

```

---

rollmean	<i>Rolling Means/Maximums/Medians</i>
----------	---------------------------------------

---

**Description**

Generic functions for computing rolling means, maximums and medians of ordered observations.

**Usage**

```
rollmean(x, k, fill = if (na.pad) NA, na.pad = FALSE,
align = c("center", "left", "right"), ...)
rollmeanr(..., align = "right")
rollmax(x, k, fill = if (na.pad) NA, na.pad = FALSE,
align = c("center", "left", "right"), ...)
rollmaxr(..., align = "right")
rollmedian(x, k, fill = if (na.pad) NA, na.pad = FALSE,
align = c("center", "left", "right"), ...)
rollmedianr(..., align = "right")
```

**Arguments**

x	an object (representing a series of observations).
k	integer width of the rolling window. Must be odd for rollmedian.
fill	a three-component vector or list (recycled otherwise) providing filling values at the left/within/to the right of the data range. See the fill argument of <a href="#">na.fill</a> for details.
na.pad	deprecated. Use fill = NA instead of na.pad = TRUE.
align	character specifying whether the index of the result should be left- or right-aligned or centered (default) compared to the rolling window of observations.
...	Further arguments passed to methods.

**Details**

These functions compute rolling means, maximums and medians respectively and are thus similar to [rollapply](#) but are optimized for speed.

Currently, there are methods for "zoo" and "ts" series and default methods. The default method of rollmedian is an interface to [runmed](#). The default method of rollmean does not handle inputs that contain NAs. In such cases, use [rollapply](#) instead.

**Value**

An object of the same class as x with the rolling mean/max/median.

**See Also**

[rollapply](#), [zoo](#), [na.fill](#)

**Examples**

```
x.Date <- as.Date(paste(2004, rep(1:4, 4:1), sample(1:28, 10), sep = "-"))
x <- zoo(rnorm(12), x.Date)

rollmean(x, 3)
rollmax(x, 3)
rollmedian(x, 3)

xm <- zoo(matrix(1:12, 4, 3), x.Date[1:4])
rollmean(xm, 3)
rollmax(xm, 3)
rollmedian(xm, 3)

rollapply(xm, 3, mean) # uses rollmean
rollapply(xm, 3, function(x) mean(x)) # does not use rollmean
```

---

window.zoo

---

*Extract/Replacing the Time Windows of Objects*

---

**Description**

Methods for extracting time windows of "zoo" objects and replacing it.

**Usage**

```
## S3 method for class 'zoo'
window(x, index. = index(x), start = NULL, end = NULL, ...)
## S3 replacement method for class 'zoo'
window(x, index. = index(x), start = NULL, end = NULL, ...) <- value
```

**Arguments**

x	an object.
index.	the index/time window which should be extracted.
start	an index/time value. Only the indexes in index which are greater or equal to start are used. If the index class supports comparisons to character variables, as does "Date" class, "yearmon" class, "yearqtr" class and the chron package classes "dates" and "times" then start may alternately be a character variable.
end	an index/time value. Only the indexes in index which are lower or equal to end are used. Similar comments about character variables mentioned under start apply here too.
value	a suitable value object for use with window(x).
...	currently not used.

**Value**

Either the time window of the object is extracted (and hence return a "zoo" object) or it is replaced.

**See Also**

[zoo](#)

**Examples**

```
## zoo example
x.date <- as.Date(paste(2003, rep(1:4, 4:1), seq(1,19,2), sep = "-"))
x <- zoo(matrix(rnorm(20), ncol = 2), x.date)
x

window(x, start = as.Date("2003-02-01"), end = as.Date("2003-03-01"))
window(x, index = x.date[1:6], start = as.Date("2003-02-01"))
window(x, index = x.date[c(4, 8, 10)])
window(x, index = x.date[c(4, 8, 10)]) <- matrix(1:6, ncol = 2)
x

## for classes that support comparisons with "character" variables
## start and end may be "character".
window(x, start = "2003-02-01")

## zooreg example (with plain numeric index)
z <- zooreg(rnorm(10), start = 2000, freq = 4)
window(z, start = 2001.75)
window(z, start = c(2001, 4))

## replace data at times of d0 which are in dn
d1 <- d0 <- zoo(1:10) + 100
dn <- - head(d0, 4)

window(d1, time(dn)) <- coredat(dn)
```

---

xblocks

*Plot contiguous blocks along x axis.*

---

**Description**

Plot contiguous blocks along x axis. A typical use would be to highlight events or periods of missing data.

**Usage**

```
xblocks(x, ...)
```

```
## Default S3 method:
```

```
xblocks(x, y, ..., col = NULL, border = NA,
        ybottom = par("usr")[3], ytop = ybottom + height,
        height = diff(par("usr")[3:4]),
        last.step = median(diff(tail(x))))

## S3 method for class 'zoo'
xblocks(x, y = x, ...)

## S3 method for class 'ts'
xblocks(x, y = x, ...)
```

### Arguments

<code>x, y</code>	In the default method, <code>x</code> gives the ordinates along the x axis and must be in increasing order. <code>y</code> gives the color values to plot as contiguous blocks. If <code>y</code> is numeric, data coverage is plotted, by converting it into a logical ( <code>!is.na(y)</code> ). Finally, if <code>y</code> is a function, it is applied to <code>x</code> ( <code>time(x)</code> in the time series methods). If <code>y</code> has character (or factor) values, these are interpreted as colors – and should therefore be color names or hex codes. Missing values in <code>y</code> are not plotted. The default color is taken from <code>palette()[1]</code> . If <code>col</code> is given, this over-rides the block colors given as <code>y</code> . The <code>ts</code> and <code>zoo</code> methods plot the <code>coredata(y)</code> values against the time index <code>index(x)</code> .
<code>...</code>	In the default method, further arguments are graphical parameters passed on to <a href="#">gpar</a> .
<code>col</code>	if <code>col</code> is specified, it determines the colors of the blocks defined by <code>y</code> . If multiple colors are specified they will be repeated to cover the total number of blocks.
<code>border</code>	border color.
<code>ybottom, ytop, height</code>	<code>y</code> axis position of the blocks. The default is to fill the whole plot region, but by setting these values one can draw blocks along the top or bottom of the plot. Note that <code>height</code> is not used directly, it only sets the default value of <code>ytop</code> .
<code>last.step</code>	width (in native units) of the final block. Defaults to the median of the last 5 time steps (assuming steps are regular).

### Details

Blocks are drawn forward in "time" from the specified `x` locations, up until the following value. Contiguous blocks are calculated using [rle](#).

**Examples**

```

## example time series:
set.seed(0)
flow <- ts(filter(rlnorm(200, mean = 1), 0.8, method = "r"))

## highlight values above and below thresholds.
## this draws on top using semi-transparent colors.
rgb <- hcl(c(0, 0, 260), c = c(100, 0, 100), l = c(50, 90, 50), alpha = 0.3)
plot(flow)
xblocks(flow > 30, col = rgb[1]) ## high values red
xblocks(flow < 15, col = rgb[3]) ## low value blue
xblocks(flow >= 15 & flow <= 30, col = rgb[2]) ## the rest gray

## same thing:
plot(flow)
xblocks(time(flow), cut(flow, c(0,15,30,Inf), labels = rev(rgb)))

## another approach is to plot blocks underneath without transparency.
plot(flow)
## note that 'ifelse' keeps its result as class 'ts'
xblocks(ifelse(flow < mean(flow), hcl(0, 0, 90), hcl(0, 80, 70)))
## need to redraw data series on top:
lines(flow)
box()

## for single series only: plot.default has a panel.first argument
plot(time(flow), flow, type = "l",
      panel.first = xblocks(flow > 20, col = "lightgray"))
## (see also the 'panel' argument for use with multiple series, below)

## insert some missing values
flow[c(1:10, 50:80, 100)] <- NA

## the default plot shows data coverage
## (most useful when displaying multiple series, see below)
plot(flow)
xblocks(flow)

## can also show gaps:
plot(flow, type = "s")
xblocks(time(flow), is.na(flow), col = "gray")

## Example of alternating colors, here showing calendar months
flowdates <- as.Date("2000-01-01") + as.numeric(time(flow))
flowz <- zoo(coredata(flow), flowdates)
plot(flowz)
xblocks(flowz, months, ## i.e. months(time(flowz)),
        col = gray.colors(2, start = 0.7), border = "slategray")
lines(flowz)

## Example of multiple series.
## set up example data

```

```

z <- ts(cbind(A = 0:5, B = c(6:7, NA, NA, 10:11), C = c(NA, 13:17)))

## show data coverage only (highlighting gaps)
plot(z, panel = function(x, ...)
  xblocks(x, col = "darkgray"))

## draw gaps in darkgray
plot(z, type = "s", panel = function(x, ...) {
  xblocks(time(x), is.na(x), col = "darkgray")
  lines(x, ...); points(x)
})

## Example of overlaying blocks from a different series.
## Are US presidential approval ratings linked to sunspot activity?
## Set block height to plot blocks along the bottom.
plot(presidents)
xblocks(sunspot.year > 50, height = 2)

```

---

xyplot.zoo

*Plot zoo Series with Lattice*

---

## Description

xyplot methods for time series objects (of class "zoo", "its", or "tis").

## Usage

```

## S3 method for class 'zoo'
xyplot(x, data, ...)

## S3 method for class 'zoo'
llines(x, y = NULL, ...)
## S3 method for class 'zoo'
lpoints(x, y = NULL, ...)
## S3 method for class 'zoo'
ltext(x, y = NULL, ...)

panel.segments.zoo(x0, x1, ...)
panel.rect.zoo(x0, x1, ...)
panel.polygon.zoo(x, ...)

```

## Arguments

x, x0, x1	time series object of class "zoo", "its" or "tis". For panel.plot.default it should be a numeric vector.
y	numeric vector or matrix.
data	not used.

... arguments are passed to `xyplot.ts`, and may be passed through to `xyplot` and `panel.xyplot`.

Some of the commonly used arguments are:

- `screens` factor (or coerced to factor) whose levels specify which graph each series is to be plotted in. `screens = c(1, 2, 1)` would plot series 1, 2 and 3 in graphs 1, 2 and 1. This also defines the strip text in multi-panel plots.
- `scales` the default is set so that all series have the "same" X axis but "free" Y axis. See `xyplot` in the **lattice** package for more information on scales.
- `layout` numeric vector of length 2 specifying number of columns and rows in the plot, see `xyplot` for more details. The default is to fill columns with up to 6 rows.
- `xlab` character string used as the X axis label.
- `ylab` character string used as the Y axis label. If there are multiple panels it may be a character vector the same length as the number of panels, but *NOTE* in this case the vector should be reversed OR the argument `as.table` set to `FALSE`.
- `lty`, `lwd`, `pch`, `type`, `col` graphical arguments passed to `panel.xyplot`. These arguments can also be vectors or (named) lists, see details for more information.

## Details

`xyplot.zoo` plots a "zoo", "its" or "tis" object using `xyplot.ts` from **lattice**. Series of other classes are coerced to "zoo" first.

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1,2), c(3,4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way.

Note that since **zoo** 1.6-3 `plot.panel.default` and `plot.panel.custom` are no longer necessary, as normal panel functions (`panel.xyplot` by default) will work.

Similarly, there are now methods for the generic **lattice** drawing functions `llines`, `lpoints`, and `ltext`. These can also be called as `panel.lines`, `panel.points`, and `panel.text`, respectively. The old interfaces (`panel.lines.zoo`, `panel.points.zoo`, and `panel.text.zoo`), will be removed in future versions. `panel.polygon.zoo` may also be removed.

## Value

Invisibly returns a "trellis" class object. Printing this object using `print` will display it.

# This will give you a spin button to choose the column to plot,
# and a button to print out the current series number.
playwith(xyplot(dat[,c(1,i)]), parameters = list(i = 1:100,
  do_something = function(playState) print(playState$env$i))

## End(Not run)

```

---

yearmon

*An Index Class for Monthly Data*

---

### Description

"yearmon" is a class for representing monthly data.

### Usage

```
yearmon(x)
```

### Arguments

x                    numeric (interpreted as being "in years").

### Details

The "yearmon" class is used to represent monthly data. Internally it holds the data as year plus 0 for January, 1/12 for February, 2/12 for March and so on in order that its internal representation is

the same as `ts` class with `frequency = 12`. If `x` is not in this format it is rounded via `floor(12*x + .0001)/12`.

There are coercion methods available for various classes including: default coercion to "yearmon" (which coerces to "numeric" first) and coercions to and from "yearmon" to "Date" (see below), "POSIXct", "POSIXlt", "numeric", "character" and "jul". The last one is from the "tis" package available on CRAN. In the case of `as.yearmon.POSIXt` the conversion is with respect to GMT. (Use `as.yearmon(format(...))` for other time zones.) In the case of `as.yearmon.character` the format argument uses the same percent code as "Date". These are described in [strptime](#). Unlike "Date" one can specify a year and month with no day. Default formats of "%Y-%m", "%Y-%m-%d" and "%b %Y".

There is an `is.numeric` method which returns FALSE.

`as.Date.yearmon` and `as.yearmon.yearqtr` each has an optional second argument of "frac" which is a number between 0 and 1 inclusive that indicates the fraction of the way through the period that the result represents. The default is 0 which means the beginning of the period.

There is also a `date` method for `as.yearmon` usable with objects created with package `date`.

`Sys.yearmon()` returns the current year/month and methods for `min`, `max` and `range` are defined (by defining a method for `Summary`).

A `yearmon` mean method is also defined.

## Value

Returns its argument converted to class `yearmon`.

## See Also

[yearqtr](#), [zoo](#), [zooreg](#), [ts](#)

## Examples

```
x <- as.yearmon(2000 + seq(0, 23)/12)
x

as.yearmon("mar07", "%b%y")
as.yearmon("2007-03-01")
as.yearmon("2007-12")

# returned Date is the fraction of the way through
# the period given by frac (= 0 by default)
as.Date(x)
as.Date(x, frac = 1)
as.POSIXct(x)

# given a Date, x, return the Date of the next Friday
nextfri <- function(x) 7 * ceiling(as.numeric(x - 1)/7) + as.Date(1)

# given a Date, d, return the same Date in the following month
# Note that as.Date.yearmon gives first Date of the month.
d <- as.Date("2005-1-1") + seq(0,90,30)
next.month <- function(d) as.Date(as.yearmon(d) + 1/12) +
```

```

as.numeric(d - as.Date(as.yearmon(d)))
next.month(d)

# 3rd Friday in last month of the quarter of Date x
as.Date(as.yearmon(as.yearqtr(x)) + 2/12) + 14

z <- zoo(rnorm(24), x, frequency = 12)
z
as.ts(z)

## convert data fram to multivariate monthly "ts" series
## 1.read raw data
Lines.raw <- "ID Date Count
123 20 May 1999 1
123 21 May 1999 3
222 1 Feb 2000 2
222 3 Feb 2000 4
"
DF <- read.table(textConnection(Lines.raw), skip = 1,
  col.names = c("ID", "d", "b", "Y", "Count"))
## 2. fix raw date
DF$yearmon <- as.yearmon(paste(DF$b, DF$Y), "%b %Y")
## 3. aggregate counts over months, convert to zoo and merge over IDs
ag <- function(DF) aggregate(zoo(DF$Count), DF$yearmon, sum)
z <- do.call("merge.zoo", lapply(split(DF, DF$ID), ag))
## 4. convert to "zooreg" and then to "ts"
frequency(z) <- 12
as.ts(z)

xx <- zoo(seq_along(x), x)

## aggregating over year
as.year <- function(x) as.numeric(floor(as.yearmon(x)))
aggregate(xx, as.year, mean)

```

---

yearqtr

*An Index Class for Quarterly Data*

---

### Description

"yearqtr" is a class for representing quarterly data.

### Usage

```

yearqtr(x)
as.yearqtr(x, ...)
## S3 method for class 'yearqtr'
format(x, format = "%Y Q%q", ...)

```

**Arguments**

x	for yearqtr a numeric (interpreted as being “in years”). For as.yearqtr another date class object. For the “yearqtr” method of format an object of class “yearqtr” or if called as format.yearqtr then an object with an as.yearqtr method that can be coerced to “yearqtr”.
format	character string specifying format. “%C”, “%Y”, “%y” and “%q”, if present, are replaced with the century, year, last two digits of the year, and quarter (i.e. a number between 1 and 4), respectively.
...	other arguments. Currently not used.

**Details**

The “yearqtr” class is used to represent quarterly data. Internally it holds the data as year plus 0 for Quarter 1, 1/4 for Quarter 2 and so on in order that its internal representation is the same as ts class with frequency = 4. If x is not in this format it is rounded via `floor(4*x + .0001)/4`.

`as.yearqtr.character` uses a default format of “%Y Q%q”, “%Y q%q” or “%Y-%q” according to whichever matches. %q accepts the numbers 1-4 (possibly with leading zeros).

There are coercion methods available for various classes including: default coercion to “yearqtr” (which coerces to “numeric” first) and coercion from “yearqtr” to “Date” (see below), “POSIXct”, “POSIXlt”, “numeric”, “character” and “jul”. The last one is from the frame package on CRAN.

There is an `is.numeric` method which returns FALSE.

There is also a `date` method for `as.yearqtr` usable with objects created with package `date`.

`Sys.yearqtr()` returns the current year/month and methods for `min`, `max` and `range` are defined (by defining a method for `Summary`).

A `yearqtr.mean` method is also defined.

Certain methods support a `frac` argument. See [yearmon](#).

**Value**

`yearqtr` and `as.yearqtr` return the first argument converted to class `yearqtr`. The `format` method returns a character string representation of its argument first argument.

**See Also**

[yearmon](#), [zoo](#), [zooreg](#), [ts](#), [strptime](#).

**Examples**

```
x <- as.yearqtr(2000 + seq(0, 7)/4)
x

format(x, "%Y Quarter %q")
as.yearqtr("2001 Q2")
as.yearqtr("2001 q2") # same
as.yearqtr("2001-2") # same
```

```

# returned Date is the fraction of the way through
# the period given by frac (= 0 by default)
dd <- as.Date(x)
format.yearqtr(dd)
as.Date(x, frac = 1)
as.POSIXct(x)

zz <- zoo(rnorm(8), x, frequency = 4)
zz
as.ts(zz)

```

---

zoo

*Z's Ordered Observations*

---

### Description

zoo is the creator for an S3 class of indexed totally ordered observations which includes irregular time series.

### Usage

```

zoo(x = NULL, order.by = index(x), frequency = NULL)
## S3 method for class 'zoo'
print(x, style = , quote = FALSE, ...)

```

### Arguments

x	a numeric vector, matrix or a factor.
order.by	an index vector with unique entries by which the observations in x are ordered. See the details for support of non-unique indexes.
frequency	numeric indicating frequency of order.by. If specified, it is checked whether order.by and frequency comply. If so, a regular "zoo" series is returned, i.e., an object of class c("zooreg", "zoo"). See below and <a href="#">zooreg</a> for more details.
style	a string specifying the printing style which can be "horizontal" (the default for vectors), "vertical" (the default for matrices) or "plain" (which first prints the data and then the index).
quote	logical. Should characters be quoted?
...	further arguments passed to the print methods of the data and the index.

### Details

zoo provides infrastructure for ordered observations which are stored internally in a vector or matrix with an index attribute (of arbitrary class, see below). The index must have the same length as `NROW(x)` except in the case of a zero length numeric vector in which case the index length can be any length. Emphasis has been given to make all methods independent of the index/time class

(given in `order.by`). In principle, the data `x` could also be arbitrary, but currently there is only support for vectors and matrices and partial support for factors.

`zoo` is particularly aimed at irregular time series of numeric vectors/matrices, but it also supports regular time series (i.e., series with a certain frequency). `zoo`'s key design goals are independence of a particular index/date/time class and consistency with `ts` and base `R` by providing methods to standard generics. Therefore, standard functions can be used to work with "zoo" objects and memorization of new commands is reduced.

When creating a "zoo" object with the function `zoo`, the vector of indexes `order.by` can be of (a single) arbitrary class (if `x` is shorter or longer than `order.by` it is expanded accordingly), but it is essential that `ORDER(order.by)` works. For other functions it is assumed that `c()`, `length()`, `MATCH()` and subsetting `[`, work. If this is not the case for a particular index/date/time class, then methods for these generic functions should be created by the user. Note, that to achieve this, new generic functions `ORDER` and `MATCH` are created in the `zoo` package with default methods corresponding to the non-generic base functions `order` and `match`. Note that the `order` and hence the default `ORDER` typically work if there is a `xtfrm` method. Furthermore, for certain (but not for all) operations the index class should have an `as.numeric` method (in particular for regular series) and an `as.character` method might improve printed output (see also below).

The index observations `order.by` should typically be unique, such that the observations can be totally ordered. Nevertheless, `zoo()` is able to create "zoo" objects with duplicated indexes (with a warning) and simple methods such as `plot()` or `summary()` will typically work for such objects. However, this is not formally supported as the bulk of functionality provided in **zoo** requires unique index observations/time stamps. See below for an example how to remove duplicated indexes.

If a frequency is specified when creating a series via `zoo`, the object returned is actually of class "zooreg" which inherits from "zoo". This is a subclass of "zoo" which relies on having a "zoo" series with an additional "frequency" attribute (which has to comply with the index of that series). Regular "zooreg" series can also be created by `zooreg`, the `zoo` analogue of `ts`. See the respective help page and `is.regular` for further details.

Methods to standard generics for "zoo" objects currently include: `print` (see above), `summary`, `str`, `head`, `tail`, `[` (subsetting), `rbind`, `cbind`, `merge` (see `merge.zoo`), `aggregate` (see `aggregate.zoo`), `rev`, `split` (see `aggregate.zoo`), `barplot`, `plot` and `lines` (see `plot.zoo`). For multivariate "zoo" series with column names the `$` extractor is available, behaving similar as for "data.frame" objects. Methods are also available for median and quantile.

`ifelse.zoo` is not a method (because `ifelse` is not a generic) but must be written out including the `.zoo` suffix.

To "prettify" printed output of "zoo" series the generic function `index2char` is used for turning index values into character values. It defaults to using `as.character` but can be customized if a different printed display should be used (although this should not be necessary, usually).

The subsetting method `[` work essentially like the corresponding functions for vectors or matrices respectively, i.e., takes indexes of type "numeric", "integer" or "logical". But additionally, it can be used to index with observations from the index class of the series. If the index class of the series is one of the three classes above, the corresponding index has to be encapsulated in `I()` to enforce usage of the index class (see examples). Subscripting by a zoo object whose data contains logical values is undefined.

Additionally, `zoo` provides several generic functions and methods to work (a) on the data contained in a "zoo" object, (b) the index (or time) attribute associated to it, and (c) on both data and index:

(a) The data contained in "zoo" objects can be extracted by `coredata` (strips off all "zoo"-specific attributes) and modified using `coredata<-`. Both are new generic functions with methods for "zoo" objects, see [coredata](#).

(b) The index associated with a "zoo" object can be extracted by `index` and modified by `index<-`. As the interpretation of the index as "time" in time series applications is more natural, there are also synonymous methods `time` and `time<-`. The start and the end of the index/time vector can be queried by `start` and `end`. See [index](#).

(c) To work on both data and index/time, zoo provides methods `lag`, `diff` (see [lag.zoo](#)) and `window`, `window<-` (see [window.zoo](#)).

In addition to standard group generic function (see [Ops](#)), the following mathematical operations are available as methods for "zoo" objects: `transpose t` which coerces to a matrix first, and `cumsum`, `cumprod`, `cummin`, `cummax` which are applied column wise.

Coercion to and from "zoo" objects is available for objects of various classes, in particular "ts", "irts" and "its" objects can be coerced to "zoo", the reverse is available for "its" and for "irts" (the latter in package `tseries`). Furthermore, "zoo" objects can be coerced to vectors, matrices and lists and data frames (dropping the index/time attribute). See [as.zoo](#).

Seven methods are available for NA handling in the data of "zoo" objects: `na.approx` which uses linear interpolation to fill in NA values. `na.contiguous` which extracts the longest consecutive stretch of non-missing values in a "zoo" object, `na.locf` which replaces NAs by the last previous non-NA, `na.omit` which returns a "zoo" object with incomplete observations removed, `na.aggregate` which uses group means to fill in NA values, `na.spline` which uses spline interpolation to fill in NA values and `na.trim` which trims runs of NAs off the beginning and end but not in the interior. An 8th NA routine can be found in the `stinepack` package where `na.stinterp` which performs Stineman interpolation.

A typical task to be performed on ordered observations is to evaluate some function, e.g., computing the mean, in a window of observations that is moved over the full sample period. The generic function `rollapply` provides this functionality for arbitrary functions and more efficient versions `rollmean`, `rollmax`, `rollmedian` are available for the mean, maximum and median respectively.

The `zoo` package has an `as.Date` numeric method which is similar to the one in the core of R except that the `origin` argument defaults to January 1, 1970 (whereas the one in the core of R has no default).

Note that since `zoo` uses date/time classes from base R and other packages, it may inherit bugs or problems with those date/time classes. Currently, there is one such known problem with the `c` method for the `POSIXct` class in base R: If `x` and `y` are `POSIXct` objects with `tzone` attributes, the attribute will always be dropped in `c(x, y)`, even if it is the same across both `x` and `y`. Although this is documented at [c.POSIXct](#), one may want to employ a workaround as shown at <https://stat.ethz.ch/pipermail/r-devel/2010-August/058112.html>.

## Value

A vector or matrix with an "index" attribute of the same dimension (`NROW(x)`) by which `x` is ordered.

---

 zooreg

*Regular zoo Series*

---

### Description

zooreg is the creator for the S3 class "zooreg" for regular "zoo" series. It inherits from "zoo" and is the analogue to [ts](#).

### Usage

```
zooreg(data, start = 1, end = numeric(), frequency = 1,
        deltat = 1, ts.eps = getOption("ts.eps"), order.by = NULL)
```

### Arguments

data	a numeric vector, matrix or a factor.
start	the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit.
end	the time of the last observation, specified in the same way as start.
frequency	the number of observations per unit of time.
deltat	the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of frequency or deltat should be provided.
ts.eps	time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than ts.eps.
order.by	a vector by which the observations in x are ordered. If this is specified the arguments start and end are ignored and zoo(data, order.by, frequency) is called. See <a href="#">zoo</a> for more information.

### Details

Strictly regular series are those whose time points are equally spaced. Weakly regular series are strictly regular time series in which some of the points may have been removed but still have the original underlying frequency associated with them. "zooreg" is a subclass of "zoo" that is used to represent both weakly and strictly regular series. Internally, it is the same as "zoo" except it also has a "frequency" attribute. Its index class is more restricted than "zoo". The index: 1. must be numeric or a class which can be coerced via `as.numeric` (such as [yearmon](#), [yearqtr](#), [Date](#), [POSIXct](#), [tis](#), [xts](#), etc.). 2. when converted to numeric must be expressible as multiples of 1/frequency. 3. group generic functions `Ops` should be defined, i.e., adding/subtracting a numeric to/from the index class should produce the correct value of the index class again.

zooreg is the zoo analogue to `ts`. The arguments are almost identical, only in the case where `order.by` is specified, `zoo` is called with `zoo(data, order.by, frequency)`. It creates a regular series of class "zooreg" which inherits from "zoo". It is essentially a "zoo" series with an additional "frequency" attribute. In the creation of "zooreg" objects (via `zoo`, `zooreg`, or coercion functions) it is always check whether the index specified complies with the frequency specified.

The class "zooreg" offers two advantages over code "ts": 1. The index does not have to be plain numeric (although that is the default), it just must be coercible to numeric, thus printing and plotting can be customized. 2. This class can not only represent strictly regular series, but also series with an underlying regularity, i.e., where some observations from a regular grid are omitted.

Hence, "zooreg" is a bridge between "ts" and "zoo" and can be employed to coerce back and forth between the two classes. The coercion function `as.zoo.ts` returns therefore an object of class "zooreg" inheriting from "zoo". Coercion between "zooreg" and "zoo" is also available and drops or tries to add a frequency respectively.

For checking whether a series is strictly regular or does have an underlying regularity the generic function `is.regular` can be used.

Methods to standard generics for regular series such as `frequency`, `deltat` and `cycle` are available for both "zooreg" and "zoo" objects. In the latter case, it is checked first (in a data-driven way) whether the series is in fact regular or not.

`as.zooreg.ts` has a class argument whose value represents the class of the index of the zooreg object into which the `ts` object is converted. The default value is "ti". Note that the frequency of the zooreg object will not necessarily be the same as the frequency of the `ts` object that it is converted from.

## Value

An object of class "zooreg" which inherits from "zoo". It is essentially a "zoo" series with a "frequency" attribute.

## See Also

`zoo`, `is.regular`

## Examples

```
## equivalent specifications of a quarterly series
## starting in the second quarter of 1959.
zooreg(1:10, frequency = 4, start = c(1959, 2))
as.zoo(ts(1:10, frequency = 4, start = c(1959, 2)))
zoo(1:10, seq(1959.25, 1961.5, by = 0.25), frequency = 4)

## use yearqtr class for indexing the same series
z <- zoo(1:10, yearqtr(seq(1959.25, 1961.5, by = 0.25)), frequency = 4)
z
z[-(3:4)]

## create a regular series with a "Date" index
zooreg(1:5, start = Sys.Date())
## or with "yearmon" index
zooreg(1:5, end = yearmon(2000))
```

```
## lag and diff (as diff is defined in terms of lag)
## act differently on zoo and zooreg objects!
## lag.zoo moves a point to the adjacent time whereas
## lag.zooreg moves a point by deltat
x <- c(1, 2, 3, 6)
zz <- zoo(x, x)
zr <- as.zooreg(zz)
lag(zz, k = -1)
lag(zr, k = -1)
diff(zz)
diff(zr)

## lag.zooreg without and with na.pad
lag(zr, k = -1)
lag(zr, k = -1, na.pad = TRUE)

## standard methods available for regular series
frequency(z)
deltat(z)
cycle(z)
cycle(z[-(3:4)])

zz <- zoo(1:6, as.Date(c("1960-01-29", "1960-02-29", "1960-03-31", "1960-04-29", "1960-05-31", "1960-06-30")))
# this converts zz to "zooreg" and then to "ts" expanding it to a daily
# series which is 154 elements long, most with NAs.
## Not run:
length(as.ts(zz)) # 154

## End(Not run)
# probably a monthly "ts" series rather than a daily one was wanted.
# This variation of the last line gives a result only 6 elements long.
length(as.ts(aggregate(zz, as.yearmon, c))) # 6

z zr <- as.zooreg(zz)

dd <- as.Date(c("2000-01-01", "2000-02-01", "2000-03-01", "2000-04-01"))
zrd <- as.zooreg(zoo(1:4, dd))
